Note: The title blocks for the Chapter 1 figures refer to “Comanche Peak S.E.S.” The plant name has changed to CPNPP, and these figure title blocks will not be updated to reflect this.

1.1 INTRODUCTION

This updated Final Safety Analysis Report (FSAR) describes the design, construction and operation of a two-unit nuclear power plant designated as the Comanche Peak Nuclear Power Plant (CPNPP), Operating Licenses NPF-87 and NPF-89 for Units 1 and 2, respectively. All future references to the Final Safety Analysis Report (or FSAR) contained in this document refer to the updated FSAR. This report follows the format recommended by Regulatory Guide 1.70, Revision 2, Standard Format and Content of Safety Analysis Reports for Nuclear Power Plants. The design information provided herein reflects the design in sufficient detail to enable a definitive evaluation as to whether CPNPP can be constructed and operated without undue risk to the health and safety of the public.

Vistra Operations Company LLC (Vistra OpCo) (operator) and Comanche Peak Power Company LLC (CP PowerCo) (owner) are subsidiaries of Vistra Corp. A simplified organizational diagram is shown in Figure 13.1-1.

Vistra OpCo - has corporate responsibility for the design, engineering, construction, licensing, operation, procurement, quality assurance and fuel management support to CPNPP.

1.1.1 STATION LOCATION

Located in Somervell County in North Central Texas, the CPNPP is about 65 miles southwest of the Dallas-Fort Worth Metropolitan Area. In addition, the Squaw Creek Reservoir (SCR), built for station cooling, extends northward into Hood County.

1.1.2 NUCLEAR STEAM SUPPLY SYSTEM

The Nuclear Steam Supply System (NSSS) for each unit is a pressurized water reactor, which along with the design and fabrication of the initial cores, is supplied by Westinghouse Electric Corporation.

1.1.3 CONTAINMENT

The containment for each unit is a steel-lined, reinforced concrete, cylindrical structure with a hemispherical dome designed by Gibbs & Hill, Inc. (Architect-Engineer).

1.1.4 CORE THERMAL POWER LEVEL

Each generating unit core was originally designed for a warranted power output of 3411 Megawatt thermal (MWt), which corresponds to a net electrical output of approximately 1150 Megawatt electric (MWe). This output, combined with the reactor coolant pump heat output of 14 MWt, gives a warranted NSSS output of 3425 MWt, which is the license application rating. A 4.5 percent increase in steam flow results in the maximum calculated NSSS output of 3579 MWt, and thus a maximum calculated core output of 3565 MWt. All safety systems, including the containment and engineered safety features, are designed for operation at the maximum calculated power output.

The thermal power output of Units 1 and 2 were subsequently increased to 3612 MWt.

1.1.5 SCHEDULE

CPNPP Unit 1 was declared for commercial operation on August 13, 1990. Unit 2 was declared for commercial operation on August 3, 1993.

1.2 GENERAL PLANT DESCRIPTION

1.2.1 SITE CHARACTERISTICS

The site of the Comanche Peak Nuclear Power Plant (CPNPP) is in an area of low population (520 persons within four miles of site) having a rural farm-ranch community setting. There are no residents within one mile of the site, and only 75 persons reside within two miles. There are approximately 12,000 persons within 10 miles of the site. The nearest communities, Glen Rose and Granbury (combined 1970 population about 4,000 persons), are 4 1/4 and 10 miles from the site, respectively. Fort Worth (1970 population about 400,000), from 33 to 50 miles from site, is the nearest major population center.

Land use in the site vicinity and surrounding area is predominantly agricultural. Dairy cattle are a minor portion of the total livestock with the closest commercial dairy herd nearly five (5) miles from the site. There is no commercial fishing in the site vicinity.

Although local population is projected to increase, no land use characteristics are projected to be drastically altered during station life. The site is well-suited for locating a nuclear generating installation because of a large exclusion area with a minimum boundary distance of 5,067 feet (1544 meters), a population center distance greater than 20 miles, a rock foundation for all seismic Category I structures, a lack of high surface water conditions, an available cooling water supply, and because of favorable hydrologic, geologic, seismic, and meteorologic conditions.

1.2.1.1 Geology and Seismology

The CPNPP site is located on the Comanche Plateau, a subdivision of the Central Texas section of the Great Plains physiographic province.

Gently dipping Lower Cretaceous limestone and sandstone directly underlie the site.

Structurally, the site occupies the south flank of the Fort Worth basin, a sedimentary depositional trough filled with Pennsylvanian and Permian sediments formed in mid-Pennsylvanian time. A regional unconformity separates the Paleozoic sediments from the lower Cretaceous sediments underlying the site.

Detailed investigation within five miles of the site has disclosed no evidence of surface faulting, thus eliminating the need for considering this factor as a design basis.

With regard to the stability of subsurface materials, there is no evidence in the site region indicating actual or potential uplift or subsidence, cavernous or karst terrain, tectonic warping or deformational zones pertinent to the site. Also not in evidence are zones of alteration, significant weathering, structural weakness, unrelieved residual stresses, or geologically hazardous materials.

Two major fault systems, the Balcones and the Luling-Mexia-Talco fault zones occur within 200 miles of the site. They are not regarded as active faults but are considered in establishing the Safe Shutdown Earthquake (SSE).

Seventeen seismic events have been reported with epicenters within 200 miles of the site. The closest large event was a modified Mercalli Intensity VII which occurred in 1882 near Bonham,

Texas, 155 miles northeast of the CPNPP. The closest known event to the site occurred 90 miles to the north in 1950 and exhibited an intensity of IV. Two events occurred 90 and 100 miles to the southeast of the site in 1932 (V-VI) and 1970 (IV), respectively. For the purpose of establishing the Safe Shutdown Earthquake (SSE), it has been assumed that a Bonham type event could occur at the closest approach of the Wichita-Ouachita tectonic subprovince to the site (70 miles). Based on these considerations, a conservative safe shutdown earthquake of 0.12g has been selected for the site. An acceleration of 0.06g has been selected for the site operating basis earthquake based on similar analysis.

In conclusion, the site is acceptable from a geologic and seismic standpoint for the facility designed for the SSE.

1.2.1.2 Hydrology

The CPNPP site is on Squaw Creek, a tributary of the Paluxy and thence Brazos rivers. Squaw Creek Reservoir (SCR) is impounded for station cooling by a dam constructed on Squaw Creek approximately 4 1/2 miles upstream of its confluence with the Paluxy and Brazos rivers.

The site grade is at elevation 810 feet, which provides 20.3 feet of freeboard above the Probable Maximum Flood (PMF) and superimposed wave runup on Squaw Creek Reservoir. The site grade is well above the maximum water levels conceivable on the Brazos River. Hence, the site will be unaffected by river flooding of any kind and will not be affected by tsunami, seiche, or ice flooding.

A continuous supply of service water is assured by means of a seismic Category I dam which encloses an arm of SCR. For the purpose of controlling the concentration of dissolved solids, SCR receives makeup water from Lake Granbury, on the Brazos River, and SCR blowdown is returned to Lake Granbury.

Most of the groundwater in the site region occurs in bedrock, although some does exist in shallow flood plain alluvium in stream valleys, but is not withdrawn for use. Bedrock aquifers pertinent to the CPNPP vicinity include, in order of increasing age, the Paluxy, Glen Rose, and Twin Mountains formations. Locally, the CPNPP and SCR are on the Glen Rose outcrop, which in turn is underlain by the Twin Mountains Formation. The Paluxy Formation is absent at the CPNPP location and is not found within the limits of the reservoir; the Glen Rose Formation is the upper most stratigraphic unit exposed in these areas.

In these formations, groundwater percolates slowly along bedrock joints and fractures, and through interstices in the rock fabric. The Twin Mountains Formation is the only moderately productive bedrock zone in the site vicinity. The Paluxy Formation has nominal pumpage near the site. The Glen Rose Formation yields very little water in the site area and is usually less productive than the other formations.

The station’s liquid waste processing system is designed so that radioactive liquid waste can be processed adequately prior to release to the environment as described in Section 11.2.

1.2.1.3 Meteorology

Located approximately 290 miles to the northwest of the Gulf of Mexico, the CPNPP site usually experiences a continental climate with marked temperature extremes both diurnally and

seasonally. Maritime tropical air masses almost completely dominate the weather in summer. During the winter, outbreaks of polar continental air are the most common frontal activity, while pacific maritime cold fronts are more frequent in the spring and fall. Wide variations in precipitation amounts occur from year to year, including both drought and persistent rains (occasionally induced by land-weakened, but rain-filled tropical cyclones from the Gulf of Mexico).

Tornado average return is about once in 320 years for the station site.

The accident dilution factors at the site are similar to those specified by Regulatory Guide 1.4 for tentative use in site evaluations. The highest frequency of poorer diffusion conditions generally occur with winds blowing toward the northwest, north-north-west, and north sectors. Some amelioration of the conditions in these sectors will be provided by the warmed waters of the SCR and by reduced topographic variation. The routine dilution factors were evaluated according to Regulatory Guide 1.111.

1.2.1.4 Environmental Radiation Monitoring

Pre-operational baseline radiological monitoring has been performed to determine the average background radiation level.

Conditions of radioactive releases are expected to be infrequent and thus contribute little dose to humans. Of primary concern are doses attributable to I-131 uptake and the submersion dose from noble gases. The primary emphasis of the operational environmental monitoring program will be to measure whole body dose from gaseous effluent and onsite sources, I-131 in air, and radionuclides (especially I-131) in milk. Radionuclides will also be measured in airborne particulate, surface water, well water, broadleaf vegetation, food products, fish, and milk. Frequency of data collection and location of measurements have been evaluated to maximize the data relating to the dose in humans.

1.2.2 PLANT DESCRIPTION

1.2.2.1 Design Criteria

The design of the CPNPP complies with Appendix A of 10 CFR Part 50, General Design Criteria for Nuclear Power Plants.

1.2.2.2 Nuclear Steam Supply System

The Nuclear Steam Supply system (NSSS) consists of a Westinghouse pressurized water reactor (PWR) and supporting auxiliary systems. The nuclear, mechanical, and thermal-hydraulic design of the reactor core is similar to the design of other Westinghouse units under construction. The rated thermal output of Unit 1 and Unit 2 is 3458 megawatt thermal (MWt). Heat balances, showing the major parameters of the plant for the original design rated power condition and maximum expected power condition and that provide bounding thermal/ hydraulic conditions for the core power uprates to 3458 MWt, are shown in Section 10.1.

Nominal performance of the NSSS based on 0 percent makeup is as follows:

		Unit 1[(a)]	Unit 2
1.	Thermal output of NSSS, MWt	3475	3474
2.	Thermal output of reactor core, MWt	3458	3458
3.	Steam flow from NSSS, lb/hr	15,334,487	15,359,775
4.	Steam pressure at a steam generator outlet, psia	967	995
5.	Maximum moisture content, percent	0.10	0.25
6.	Assumed feedwater temperature at steam generator inlet, °F	441.6 (HB) 443 (BE)	441.5

a) Based on nominal performance after 1RF12 [1 and 2].

1.2.2.2.1 Reactor Core

The reactor core is a multi-regions core composed of slightly enriched uranium dioxide pellets enclosed in pressurized, cold worked, sealed Zircaloy tubes. The fuel tubes are grouped and supported in fuel assemblies of the canless type. The basic fuel assembly consists of the control rod guide thimbles attached to the grids and the top and bottom nozzles. The fuel rods are held by the grids in the assembly to provide for very stiff support.

The initial loading of fuel into the core is designed so that fuel assemblies with the highest enrichment are placed in the outer region of the core while the two groups of fuel assemblies with lower enrichment are selectively arranged in the central region. During refueling operations, a portion of the fuel is discharged, and new fuel is loaded into the core. The fuel in the reactor core is arranged to achieve an acceptable power distribution.

Control rod assemblies are inserted into the guide thimbles of the fuel assemblies. The absorber sections of the control rods are fabricated from silver-indium-cadmium and sealed in stainless steel tubes. Neutron control for slow transients is provided by means of boric acid in solution in the Reactor Coolant System (RCS).

Each control rod cluster is attached to a spider connector and drive shaft. The drive mechanisms for the control rod assemblies are equipped with magnetic latches which are controlled by three magnetic coils and the latches are designed so that upon loss of power to the coils, the rod cluster control assembly (RCCA) is released and falls by gravity into the reactor core, effecting a shutdown of the reactor.

The reactor core rated thermal power for Unit 1 prior to 1RF09 is 3411 MWt; this results in a NSSS thermal power of approximately 3427 MWt with the additional 16 Mwt (approximate) of energy input to the RCS by nonreactor sources such as pump heat.

The reactor core thermal power for Unit 1 (after 1RF09) and Unit 2 is 3458 Mwt; this results in a NSSS thermal power of approximately 3474 Mwt with the additional 16 Mwt (approximate) of energy input to the RCS by nonreactor sources such as pump heat.

1.2.2.2.2 Reactor Coolant System

The Reactor Coolant System (RCS) consists of four parallel, similar, heat transfer loops, each consisting of a reactor coolant pump and steam generator, connected to the reactor vessel. In addition, the system includes a pressurizer, pressurizer relief tank, connecting piping, and the instrumentation necessary for operational control and protection.

The RCS transfers the heat developed in the reactor core to the steam generators, where steam is generated to drive the plant turbine- generator. Borated, demineralized light water is used as the heat transfer medium for the RCS and is circulated at a flow rate and temperature consistent with achieving the desired thermal-hydraulic performance for the reactor core. The water of the RCS also serves as neutron moderator, reflector, and solvent for the neutron absorber.

The reactor coolant pumps are Westinghouse vertical, single stage, centrifugal pumps of the shaft-seal type. The power supply systems for the pumps are designed to provide for adequate coolant flow to the reactor core under all required conditions.

The steam generators are Westinghouse vertical U-tube units containing Inconel tubes and equipped with integral moisture separation equipment to reduce the moisture content of the steam to 0.10 percent for Unit 1 and to 0.25 percent or less for Unit 2.

All reactor coolant piping as well as all pressure-containing and heat transfer surfaces in contact with the reactor water is stainless steel clad expect for the fuel tubes and steam generator tubing which are Zircaloy and Inconel, respectively. The reactor core internals, including the control rod drive shafts, are primarily stainless steel.

The electrically heated pressurizer, which is connected to one of the four parallel reactor coolant loops (RCLs), is designed to perform the following functions:

1. To maintain the pressure of the RCS during normal operation

2. To limit the pressure variations during plant loading transients

3. To maintain the RCS pressure within the design limits during abnormal occurrences.

1.2.2.3 Engineered Safety Features

The engineered safety features (ESF) systems are designed to limit the potential radiation exposure to the public as well as to plant personnel in the event of a postulated accidental release of radioactive fission products from the reactor system, particularly as the result of a loss-of-coolant accident (LOCA). These ESF function to localize, control, mitigate, and terminate all such postulated accidents to ensure that the guidelines of 10 CFR Part 100 for exposure limits are not exceeded.

The following is a list of ESF:

1. Containment

2. Containment Spray System

3. Containment spray chemical additive subsystem

4. Containment Isolation System

5. Combustible Gas Control Systems

6. Emergency Core Cooling System (ECCS)

7. Control Room habitability systems

8. Residual Heat Removal (RHR) System

Each of the ESF systems is missile-protected and designed to withstand all normal and accident loads including the Safe Shutdown Earthquake (SSE).

1.2.2.3.1 Containment

The containment is a steel-lined, reinforced concrete structure which consists of a vertical cylinder with a hemispherical dome supported on a foundation mat with a reactor cavity pit. The interior steel liner is constructed with carbon steel plate for leaktightness.

The Containment Building completely encloses the reactor and the RCS. An interior structure within the Containment Building supports and provides shielding for the reactor and other components of the NSSS.

The containment is designed to withstand the pressures and temperatures resulting from a spectrum of LOCAs and secondary system breaks.

1.2.2.3.2 Containment Spray System

The Containment Spray System, including the containment spray chemical additive subsystem, is designed to meet the following criteria:

1. To ensure that the containment pressure and temperature do not exceed the design parameters for all accidents including LOCAs

2. To ensure that offsite radiological consequences are within the limits of 10 CFR Part 100 by reducing the fission product concentration with containment

The Containment Spray System initially supplies the containment atmosphere with borated water drawn from the Refueling Water Storage Tank (RWST). When the water level in the RWST reach the low-level set point, water is drawn from the Containment sump and recirculated through the Containment spray heat exchangers to provide for the continued cooling of the containment atmosphere.

1.2.2.3.3 Containment Spray Chemical Additive Subsystem

The containment spray chemical additive subsystem is designed to insure that the concentration of the iodines within the Containment, following all postulated accidents, is reduced to limit the offsite radiological consequences.

The desired reduction in containment iodine concentration is accomplished by the injection of sodium hydroxide from the containment spray chemical additive subsystem into the containment spray water; this chemically-treated water absorbs the fission product iodines from the containment atmosphere and retains them in solution in the containment sump.

The containment spray chemical additive subsystem, together with the balance of the Containment Spray System, is designed as follows:

1. To be fully redundant

2. To meet the single failure criterion

3. To withstand all normal and accident loads

4. To be fully missile-protected

1.2.2.3.4 Containment Isolation System

In the event of postulated accidents, the Containment Isolation System is designed to minimize the leakage of radioactive materials through fluid lines penetrating Containment.

This design objective is achieved by the use of double isolation barriers. The use of double isolation barriers ensures that no single failure of any active or passive component renders the Containment Isolation System partially or wholly inoperable. The isolation valves are checked regularly during normal unit operation and are designed to assume a fail-safe position.

The Containment Isolation System ensures that the offsite radiological consequences of a main steam line rupture or LOCA are within the guidelines of 10 CFR Part 100.

1.2.2.3.5 Combustible Gas Control Systems

Combustible gas control systems are not required to be Engineered Safety Feature Systems.

The hydrogen purge system, a non-safety system, is designed to meet seismic category II requirements. This system purges the containment atmosphere through filters which reduce radioactive releases. See Section 6.2.5 for details.

1.2.2.3.6 Emergency Core Cooling System

The ECCS, with active and passive subsystems, is designed to perform the following functions:

1. To inject borated water into the RCS following a LOCA to minimize core-damage, metal-water reactions, and fission-product releases

2. To ensure adequate shutdown margin regardless of temperature

3. To provide for long-term postaccident cooling of the reactor core by recirculating borated water from the containment sump

1.2.2.3.7 Control Room Habitability Systems

The Control Room habitability systems are designed to ensure that the Control Room is habitable for a period not less than 30 days following any LOCA.

The Control Room air-conditioning system has a recirculation mode designed to maintain Control Room ambient conditions suitable for personnel occupancy during accident conditions. A set of emergency filtration units removes airborne activity from outside air during emergency pressurization and filtration modes of operation.

Communication and domestic facilities are provided to meet personnel needs during an extended stay in the Control Room area.

1.2.2.3.8 Residual Heat Removal System

The RHR System serves as a part of the ECCS during both the low pressure injection and recirculation phases following a LOCA. The RHR System is designed to provide an adequate supply of water for cooling of the reactor core; this is accomplished by the RHR pumps delivering water from the RWST to the RCLs. When the supply of refueling water is depleted, recirculation of containment sump water through a heat exchanger is initiated and maintained to ensure continued core cooling.

1.2.2.4 Plant Instrumentation and Control System

Instrumentation and controls are provided to monitor and maintain plant parameters within the prescribed operating ranges.

Reactor control is provided by the following:

1. Temperature coefficients of reactivity

2. Control rod cluster motion

3. Injection of neutron absorbing chemical shim in the form of boric acid

The control rod clusters provide for load-follow transients as well as for startup and shutdown requirements. The chemical shim is inserted during cold shutdown, partially removed during startup, and further adjusted during the lifetime of the core to compensate for such effects as fuel consumption and accumulation of fission products which act to decrease the excess reactivity of the core.

The reactor control system permits the plant to accept 10 percent step-load increases and ramp load increases of 5 percent per minute over the load-range of 15 to 100 percent of full power. Step-and ramp-load reductions of the same magnitude are also possible over the range of 15 to 100 percent of full power.

The non-nuclear-safety-related process and containment instrumentation measure temperatures, pressure, flows, and levels in the steam and auxiliary systems and in the Containment. Process variables required on a continuous basis for startup, operation, and shutdown of the unit are indicated, recorded, and controlled from the Control Room. The quantity and types of process instrumentation provided ensure safe and orderly operation of all systems and processes over the full operating range of the plant.

The nuclear-safety-related instrumentation and control systems provide automatic protection and exercise proper control to ensure safe reactor operation and to provide initiating signals to mitigate the consequences of design basis accidents (DBAs). Supervision of both nuclear and turbine generator plants is accomplished from the Control Room.

1.2.2.5 Power Conversion and Electrical Systems

The electrical systems transmit the output of the generator units to the utility system and provide power for plant auxiliary loads. Independent and redundant Class 1E standby power systems function during a DBA to ensure operation of necessary safety-related systems.

The main generator for each unit is rated 1410 MVA at 0.90 power factor, 22 kV, 60 Hz, three-phase, 1800 rpm. Power output from each generator is fed to its respective main step-up transformer bank through the isolated phase bus system. Generator voltage is stepped up to 345 kV and transmitted through overhead transmission lines to the 345 kV Switchyard where distribution to the utility system is accomplished. Seven 345 kV transmission lines connect the Switchyard to other switching stations in the Transmission Operator's transmission system. The AC station power is distributed through the 6900 V, 480 V, and 118 V uninterruptible AC auxiliary bus systems to the unit loads. The DC load requirements are satisfied by 125-V, 125⁄250-V, and 24⁄48-V systems.

During normal operation, the main generators supply power to all the auxiliary loads except for the loads connected to the emergency buses.

These loads are normally energized from the offsite power systems. Startup and shutdown power is derived from two independent offsite power circuits. One circuit is connected to the 345 kV Switchyard, and the second feeder is connected to the 138 kV system. Each high voltage circuit is transformed through startup transformers to 6900 V.

Under LOCA and loss-of-offsite power conditions, power to the safety-related loads is achieved through the standby diesel generator system. A total of four 100 percent diesel generators, two per unit, is provided. Each diesel generator is assigned to a specific safeguard bus. One diesel generator and its associated bus and loads can satisfy the safety load requirements for one unit. There is no sharing of diesel generators.

Each unit has two independent Class 1E 125-VDC systems to provide DC and uninterruptible AC power to essential plant instruments and controls. An independent 125/250-VDC system is provided for each unit to supply non-Class 1E power and control loads.

1.2.2.6 Fuel Handling and Storage System

The Fuel Handling System is designed to permit the handling of spent fuel under water from the time it leaves the reactor vessel during refueling until it is placed in a cask for offsite shipment.

The transfer of spent fuel under water provides both a transparent radiation shield and a reliable cooling source for the removal of residual and decay heat.

The Fuel Handling System is located in two separate areas. The first area is comprised of the refueling cavity inside the Containment Building, which is flooded during the refueling operations; the second area is the Fuel Building, which includes two spent fuel pools; a cask pit and connecting fuel transfer canal, and which is external to the Containment Building and accessible to authorized personnel. The two areas of the Fuel Handling System are connected by the Fuel Transfer System, which moves the fuel through an opening in the Containment. The Fuel Handling System provides for the safe handling of RCCA under all conditions and for the required assembly, disassembly, and storage of reactor internals. This system includes a refueling machine located inside the Containment above the refueling cavity Fuel Transfer System (which includes a fuel transfer tube), a fuel handling crane above the fuel storage racks area, the RCCA changing fixture, and lifting devices (which are used for handling the reactor vessel head and internals).

The new fuel assemblies can be stored in racks in the new fuel pit, in racks in the spent fuels pools, or in the in-containment storage racks. In each of the locations, the new fuel is separated by sufficient distance to preclude criticality. Spent fuel is placed in storage racks in the spent fuel pools where it will remain for a sufficient decay and cooling period before shipment in a cask to a fuel reprocessing facility or a storage facility.

1.2.2.7 Cooling Water Systems

Two separate closed-loop cooling water systems are provided to facilitate heat removal from ESF, safety-related, and non-safety- related equipment. These are the Component Cooling Water System (CCWS) and the Turbine Plant Cooling Water (TPCW) System. Cooling for the CCWS is provided by the Station Service Water System (SSWS) and the heat is ultimately rejected to the Safe Shutdown Impoundment (SSI). Cooling for the TPCW System is provided by the Circulating Water System and this resulting heat is ultimately rejected to the Squaw Creek Reservoir (SCR).

The design criteria for the CCWS are as follows:

1. To remove residual heat from the RCS by means of the RHR System during plant shutdown

2. To cool the letdown flow to the CVCS during power operation

3. To dissipate waste heat from containment and auxiliary components

4. To remove ESF heat loads after an accident

The CCWS transfers heat to the SSWS via the component cooling water heat exchangers.

The CCWS consists of two separate and independent full capacity, safeguards-related, redundant trains of pumps and heat exchangers to remove heat from the engineering safeguards components and a nonredundant, safety-related loop with an ANS non-safety-class-related portion. Corrosion inhibiting demineralized water is circulated through the CCWS. The CCWS is maintained at a higher pressure than the SSWS to prevent inleakage of potentially corrosive

station service water fluids. The CCWS provides an intermediate barrier between the RCS and the service water system to preclude direct leakage of radioactive material to the SSI.

An uninterrupted supply of water for the service water system is ensured by the SSI, a seismic Category I structure. Makeup water for the SSI is provided via a shallow canal connecting it with the SCR and can be provided via a bleed-off from the Circulating Water System.

The design criterion for the TPCW System is to remove waste heat from various Turbine Building auxiliaries.

The TPCW System passes its heat load via the TPCW heat exchanger to the Circulating Water System.

Cooling water for the main condensers is provided by the Circulating Water System. The Circulating Water System Intake Structure is located north of the plant on the SCR. The heated water of the Circulating Water System is discharged to the SCR via a discharge tunnel at a point southeast of the plant.

1.2.2.8 Auxiliary Systems

The auxiliary systems are designed to perform the following functions:

1. To supply RCS water requirements

2. To purify reactor coolant water

3. To introduce chemicals to inhibit corrosion

4. To introduce and remove chemicals for reactivity control

5. To cool system components

6. To remove residual heat during a portion of the reactor cooling period and when the reactor is shut down

7. To cool the spent fuel pool water

8. To permit sampling of reactor coolant

9. To provide for safety injection

10. To vent and drain the RCS and the auxiliary systems

11. To provide containment ventilation and cooling

12. To provide plant fire protection

The principal auxiliary systems are the following:

1. Chemical and Volume Control System (CVCS)

2. Sampling systems

3. Compressed air systems

4. Plant ventilation systems

5. Station Service Water System (SSWS)

6. Plant Fire Protection System

7. Spent Fuel Pool Cooling and Cleanup System

1.2.2.8.1 Chemical and Volume Control System

Performance of the following functions will establish the design criteria of the CVCS:

1. Purification of reactor coolant fluid

2. Corrosion control

3. Regulation of reactor coolant inventory

4. Reactivity shim

5. Seal water injection for reactor coolant pumps

During power operation, a continuous feed-and-bleed system is maintained to and from the RCS. The bypassed fluid is depressurized, cooled, purified, and stored by a series of valves, heat exchangers, demineralizers, and tanks. Furthermore, the amount of reactor coolant is automatically adjusted to compensate for changes in volume as a result of coolant temperature changes. The CVCS provides reactivity control by varying the boron concentration in the reactor coolant.

Water for the reactor coolant pump shaft seals is supplied from the charging pump.

The centrifugal charging pumps associated with the CVCS also serve as the high-head pumps for the ECCS. In the event of a LOCA, the CVCS is isolated except for the charging pumps, which inject borated water into the reactor core.

1.2.2.8.2 Sampling Systems

The CPNPP is equipped with three sampling systems: the Primary Sampling System, the Secondary Sampling System and the Post Accident Sampling System (PASS). The Primary Sampling System serves the RCS and its auxiliary systems while the Secondary Sampling System serves the feedwater and main steam systems. The PASS no longer functions, as described in FSAR Section II.B.3. These systems provide a determination of both the chemical and radiological makeup of various plant fluids. Samples drawn from radioactive sources are passed through sample coolers or delay coils, or both, as required.

1.2.2.8.3 Compressed Air Systems

Each of the two CPNPP units are equipped with oil-free air compressors, which discharge filtered and dried compressed air into the Instrument Air System. There are two instrument air compressors for each unit and two common instrument air compressors which can be aligned to either unit. An oil-flooded common compressor supplies both units with unfiltered compressed air into a separate Service Air System.

The Service Air System provides compressed air for routine maintenance at various stations throughout the plant.

The Instrument Air System provides compressed air, which is dried and filtered, for all air-operated instruments and valves.

1.2.2.8.4 Plant Ventilation System

To facilitate the independent control of the atmosphere in various plant areas, separate ventilation systems have been provided. The following major areas are served by separate ventilation system:

1. Containment Building.

2. Auxiliary, Safeguards, and Fuel Building.

3. Turbine Building.

4. Diesel Generator Building.

5. Control Room.

6. Uninterruptible Power Supply and Distribution Room.

In addition, a Containment Purge System and a Containment Preaccess Filtration System are provided for the containment atmosphere.

1.2.2.8.5 Station Service Water System

The SSWS removes heat from the CCWS to meet the cooling requirements of the plant as follows:

1. During normal operations

2. Following shutdown

3. During and after all postulated LOCAs

The SSWS is assured of a constant supply of water by the SSI Dam which is a seismic Category I structure founded on bedrock. The SSI maintains the necessary volume of water required by NRC Regulatory Guide 1.27. Makeup water is provided via a shallow canal to the SCR and can be provided via a bleed-off from the Circulating Water System.

The SSWS of each of the units is completely independent and redundant. Each unit has two fully independent trains, either of which can supply the required cooling waterflow. The pumps and heat exchangers of each train can be aligned with the other train in the event of a component failure.

1.2.2.8.6 Plant Fire Protection System

The Fire Protection system provides means for detecting, alarming, and extinguishing fires. The system is divided into two basic subsystems: the Fire Detection System and the fire extinguishing system. The Fire Detection System is a plantwide instrumentation system provided to detect fires in various areas of the plant and to alert the Control Room operators of a fire and its location. The fire extinguishing system includes such fire fighting equipment as sprinkler systems (wet pipe, deluge and preaction), water spray, standpipe and hose stations, Halon Systems, and portable extinguishers. The Fire Protection System is not required to ensure the integrity of the reactor coolant pressure boundary (RCPB), the capability to shut down the reactor, and the capability to prevent or mitigate the consequences of accidents which could result in potential offsite exposures as detailed in 10 CFR Part 100.

All fire protection piping in Category I structures is classified Class 5 as described in Section 3.2.2.

The station fire main system, including the associated pumps, piping, and valves, is shared by the two CPNPP units.

Noncombustible and fire-resistant materials are selected where practical for use throughout the CPNPP facility, particularly in controlled-access portions of the plant such as the Containment and Control Room.

1. Fire Detection System

   A Fire Detection System is provided throughout the plant. When a fire is detected, the respective zone and fire indication appears on the local zone panel and the main fire detection panel in the Control Room. An alarm indicating lamp illuminates in the base of the ionization detectors indicating the actuated detector, for other types of detectors a lamp illuminates at the local zone panel. The majority of detectors are placed overhead in their respective areas. Also, detectors located in areas protected by halon and automatic open head water spray systems actuate the fixed systems. Detectors sound an alarm condition via the Control Room fire detection panel.

   The Fire Detection System uses fire, smoke, and heat detection devices located throughout the entire plant; they include the following:

   a. Ionization smoke detectors

      Ionization detectors are of the two-chamber-type design. The first is a reference chamber to compensate against the sensitivity changes due to temperature, barometric pressure, and humidity variations. The second chamber is a sensing chamber open to the outside elements through a protective screening which permits combustion products to enter while preventing insects and foreign matter from entering and causing false alarms.

b. Thermal detectors

Spot-type thermal detectors are of the fixed-temperature, rate compensation type.

Continuous strip thermistor heat detectors are used to monitor the temperature of charcoal adsorber beds of the atmosphere cleanup units, and other areas where accurate measurement of temperatures for fire detection is required. The strip thermistors are of the negative coefficient of resistance type.

c. Flame detectors

Flame detectors are of the ultraviolet (UV) radiation sensing type. The detectors respond to the UV frequency of radiation given off by a fire. The UV flame detectors are installed with high ceilings or specific pieces of equipment which contain highly flammable materials.

The detectors are strategically positioned throughout the facility to detect fires, annunciate alarms in the Control Room and indicate the location of the fire on the Control Room fire detection panel and local zone panel.

The detection system is electrically supervised. Class A supervision is used in the cable spreading rooms. As a minimum, class B supervision is used in the remainder of the plant.

2. Fire Extinguishing System

The fire extinguishing system uses portable extinguishers, in conjunction with hose stations and fixed suppression systems, as primary and secondary means of suppression. Water is supplied for the standpipes and suppression systems from two dedicated above ground storage tanks via an underground piping distribution system and water supply lines for each building and transformer branch from the underground loop; every branch has a post indicator gate valve for isolation of the branch or building. The main loop is divided into sections by post indicator valves to allow isolation of the loop in case of a line break. There are three 50 percent capacity fire pumps to supply water to the system. One is an electric motor driven pump and the other two pumps are diesel engine driven. Water is supplied to the underground fire loop by the lead pump, the electric motor-driven pump, when the jockey pump cannot maintain the system pressure above a predetermined set point.

A siamese fire department connection is provided for emergency fill of the system by a fire truck or a portable auxiliary pump. This fill is used as a backup to the pumps. As required by National Fire Protection Association (NFPA) No. 24, a check valve and a ball drip valve are provided for the connection of the siamese to the main loop. The siamese connection is located adjacent to the Service Water Intake Structure.

The Safeguards, Fuel Handling, and Auxiliary buildings have internal loops to supply suppression and standpipes systems. These loops have multiple connections to the underground loop. Valves are available for isolation of sections of the loops as well as isolation of the internal loop from the underground loop. Each suppression and standpipe

system has a shutoff valve to facilitate work on the system. Approved control valves are located in the respective system in accordance with applicable NFPA standards.

The Turbine Buildings have an internal loop to supply standpipes. This internal loop has multiple connections to the underground loop in Unit 1 and Unit 2. Crosstie lines are provided between Unit 1 and Unit 2 Turbine Buildings to facilitate isolation of sections of either loop. Valves are provided in accordance with NFPA No. 14 to control the waterflow and isolate the system. The water spray and automatic sprinkler systems are connected to the outside loop via isolation valves located in the fire protection valve rooms, which are accessible from inside and outside the Turbine Buildings, as required, to control the waterflow to the suppression systems.

The suppression systems for the diesel generator day tanks are supplied from the main loop independent of each other. Each system has a deluge valve, a cutoff valve, and a detection system. Actuation of one system does not affect operation of the other diesel generator; each diesel generator compartment is provided with a watertight door to prevent flooding of the adjacent areas. The systems are actuated automatically based on detection of a fire or manually adjacent to the respective area. The systems can only be shut off manually at the valve.

The fire pump house structure is protected by an automatic wet-pipe sprinkler system. Water flow and valve tamper alarms are provided at the pump house location and in the Control Room.

The deluge water spray systems for the atmosphere cleanup units, except the containment preaccess units, are supplied by the interior building supply loop. The preaccess units are supplied by the Demineralized Water System. Should demineralized water be unavailable, the operator can manually route fire protection water through the demineralized water piping. Actuation of one system will not affect the operation of an adjacent atmosphere cleanup unit.

The halon system for each cable spreading room consists of a detection system, storage cylinders, manifold and header assembly, control valves, piping, nozzles, and local control panel. Each system is designed with two charges of halon. Halon is released automatically after receipt of a fire signal from detectors located in the cable spreading room. The Unit computer rooms are each provided with a manually actuated halon system, and ionization smoke detection provides control room personnel notification of a fire.

1.2.2.8.7 Spent Fuel Pool Cooling and Cleanup System

The Spent Fuel Pool Cooling and Cleanup System serves the spent fuel pools of both units.

The cooling portion of this system has two trains consisting of a pump, heat exchanger, and other associated equipment.

The purification portion of this system consists of two trains containing a filter and a demineralizer which can be operated in parallel with either of the two cooling trains.

The skimmer portion of this system consists of a single skimmer train and is shared between both pools.

1.2.2.9 Waste Processing Systems

The waste processing systems (WPS) are designed to process liquid, gaseous, and solid waste while achieving the lowest reasonable radioactive release to the environment available through current technology. Liquid and gaseous wastes to be recycled within the plant are first segregated from those to be processed or shipped offsite.

Segregation of wastes is consistently maintained in the subsystems to ensure proper handling.

The Liquid Waste Processing System (LWPS) is designed to perform the following functions:

1. To collect reactor grade water
2. To process reactor grade water
3. To recycle reactor grade water
4. To collect floor drains and laundry waste
5. To process floor drains and laundry waste
6. To recycle or discharge processed floor drain and laundry waste
7. To remove radioactive constituents
8. To concentrate the removed radioactive constituents
9. To process concentrated radioactive constituents for solidification and shipment offsite

In addition, all liquid wastes are sampled and activity levels recorded prior to release. All processed liquid effluents from the RCS are subjected to purification by the CVCS ion exchanger in addition to the components of the WPS. The limits established by 10 CFR Part 20 are met.

The Gaseous Waste Processing System (GWPS) is designed to perform the following functions:

1. To reduce fission product gas concentrations in the RCS during normal operation
2. To contain indefinitely the fission product gases removed from the RCS
3. To collect gases generated by other systems
4. To maintain a low level of hydrogen gas in the collected gases
5. To discharge radioactive effluents after monitoring for radioactivity via a controlled path to ensure that the expected offsite doses are as low as reasonably achievable (ALARA)

The waste gases generated during plant operations including anticipated operational occurrences are collected and processed and are stored in waste gas decay tanks.

The Solid Waste Management System is designed:

1. To provide a means of encapsulating or compacting radioactive solid wastes generated by reactor plant operations

2. To provide adequate equipment and storage area shielding for the protection of operating personnel pending shipment of waste to disposal facilities

3. To measure and record the radiation levels of the solid waste processed for shipment from the site to disposal facilities

4. To provide a 3- to 6-month storage capacity for the processed wastes depending upon plant operation.

Solid wastes are compacted into containers for offsite disposal.

The WPS, with the exception of the equipment associated with the reactor coolant drain tanks, are completely shared. The reactor coolant drain tanks and associated equipment are located inside their respective Containment structures.

1.2.2.10 Safe Shutdown Impoundment

The SSI is an enclosed body of water formed from a cove of the SCR and is retained by a seismic Category I dam. It is designed and constructed to withstand the most severe postulated natural phenomena. The water level of the SSI is maintained by a spillway between the SSI and the reservoir behind the Squaw Creek Dam.

Since the Squaw Creek Dam is not a seismic Category I structure, it is assumed that ground motion from the SSE results in catastrophic, total, and instantaneous drawdown of the water level on the downstream side of the SSI Dam. The spillway limits the low water level in the SSI to 769 ft 6 in, at which point the volume of water contained is approximately 300 acre-feet.

The SSI is designed to serve as the ultimate heat sink of the CPNPP and acts to dissipate heat rejected by the SSWS during postaccident shutdown and normal cooldown conditions. It has been sized to provide adequate cooling capacity for the CPNPP in accordance with the requirements of NRC Regulatory Guide 1.27.

The materials used in construction of the SSI Dam include limestone rock from excavation at the plant site, clay from a borrow area located upstream from the Squaw Creek embankment, and a granular filter zone material.

1.2.2.11 Shared Structures, Systems, and Components

1.2.2.11.1 Shared Structures

The following structures are shared by both units of the CPNPP:

1. Auxiliary Building, including Control Room

2. Fuel Building

3. Service Water Intake Structure

4. Circulating Water Intake Structure

5. Circulating Water Discharge Structure

1.2.2.11.2 Shared Systems

The following systems are shared (or have shared components) by both units of the CPNPP:

1. Chemical and Volume Control Systems (CVCS)

2. Boron Recycle System (BRS)

3. Compressed Air Systems (CASs)

4. Station Service Water System (SSWS)

5. Waste Processing Systems (WPS)

6. Fire Protection Systems

7. Hydrogen Purge System

8. Turbine Building ventilation system

9. Control Room ventilation system

10. Primary Plant ventilation system

11. UPS and Distribution Room Ventilation System

1.2.2.11.3 Shared Components

The following components are shared by both units of the CPNPP:

1. Fuel handling equipment (in Fuel Building only)

2. Startup transformers

3. 480-V motor control centers feeding to the common services systems (mechanical) load and lighting

4. Control Room panels where common services controls are located

1.2.2.12 General Arrangements

Figure 1.2-1 through Figure 1.2-46 provide sufficient detail of major structures and equipment to give an understanding of the general layout of the plant. Plan and elevation drawings are provided for the following structures:

1. Containment and Safeguards Buildings (Unit 1)

2. Containment and Safeguards Buildings (Unit 2)

3. Turbine Building (Unit 1)

4. Turbine Building (Unit 2)

5. Auxiliary and Electrical Control Building

6. Fuel Building

7. Circulating Water Intake Structure

8. Service Water Intake Structure

These figures are based on plant plan and elevation drawings. As such, the figures provide additional detail beyond what is necessary for general arrangements. These figures will be updated as necessary to provide a reasonable understanding of the general arrangement of major plant structures and equipment. The additional detail on these drawings is not updated.

1.2.2.13 References

1. TXU Letter CPSES-200401793, Transmittal of Contract Information - Best Estimate Feedwater Temperature, July 20, 2004.

2. Design Specification No. 418A23, Revision 2, Comanche Peak Nuclear Power Plant Unit 1, Delta 76 Replacement Steam Generator, September 2006.

1.2.3 OLD STEAM GENERATOR STORAGE FACILITY

The Old Steam Generator Storage Facility (OSGSF), shown in Figure 1.2-1, is a reinforced concrete structure supported on a reinforced concrete footing. The OSGSF consists of precast concrete wall closure panels and a reinforced concrete roof slab supported by structural steel beams. The OSGSF provides a secure long-term on-site storage facility for the four Unit 1 Old Steam Generators and Old Reactor Vessel Heads (and associated Control Rod Drive Mechanisms) for Units 1 and 2.

1.2.4 INDEPENDENT SPENT FUEL STORAGE INSTALLATION

The CPNPP site contains an Independent Spent Fuel Storage Installation (ISFSI) as shown on Figure 1.2-1. The ISFSI consists of a concrete pad with space for 84 natural convection air-cooled, HI-STORM shielded dry spent fuel storage casks, each capable of storing 32 spent nuclear fuel assemblies in a welded multiple purpose container. The ISFSI is inside a separate security protected area.

1.2.5 BEYOND DESIGN BASIS

1.2.5.1 NRC Order EA-12-049 Beyond Design Basis External Events

On March 12, 2012, the NRC issued Order EA-12-049, "Order to Modify Licenses with Regard to Requirements for Mitigation Strategies for Beyond-Design-Basis External Events." Strategies,

details, and programmatic controls for mitigating beyond-design-basis external events are contained in site specific program documents. The CPNPP site contains a FLEX Storage Building as shown on Figure 1.2-1. The FLEX Storage Building protects equipment credited for NRC Order EA-12-049. Modifications to a Structure, System, or Component (SSC) required by the strategies of NRC Order EA-12-049 and are reflected in the FSAR flow diagrams as required.

1.2.5.2 NRC Order EA-12-051 – Spent Fuel Pool Instrumentation

On March 12, 2012, the NRC issued Order EA-12-051, “Order to Modify Licenses with Regard to Reliable Spent Fuel Pool Instrumentation.” Details and programmatic controls are contained in site specific program documents. The instrument display for the wide range spent fuel pool instrumentation is installed in compliance with NRC Order EA-12-051 and is readily accessible during postulated events and allows for SFP level information to be promptly available to decision makers. As appropriate, Sections 9.1.3.2 and 9.1.3.5 and Tables 17A-1 and 17A-2 refer to the wide range Spent Fuel Pool Instrumentation installed in accordance with the NRC Order.

1.3 COMPARISON TABLES

1.3.1 DELETED.

1.3.2 COMPARISON OF FINAL AND PRELIMINARY DESIGNS

Table 1.3-2 details the significant design changes that have been made since the submittal of the PSAR.

The FSAR is complete and does not rely on information contained in the PSAR. The original intent of this table was to provide a comparison with the PSAR when the FSAR was initially submitted for NRC Staff review. The information in this table is considered historical and will not be updated.

TABLE 1.3-1
THIS TABLE HAS BEEN DELETED

TABLE 1.3-2
DESIGN CHANGES SINCE PSAR SUBMITTAL

(Sheet 1 of 30)

(See Note 1)

Systems or Components	CPNPP/FSAR Section	Changes
I. Structures		
Category I Structures (other than containment)	3.8	Leak chase system behind liner of outdoor Category I tanks has been eliminated.
		The requirement for roof blow out panels above the main steam lines in the Safeguards Building has been deleted.
Control Room	3.11B	Limiting environmental conditions have been reduced to 80°F and 60 percent relative humidity.
	6.4 3.11B	Positive pressure of 1/2 inch water gauge changed to 0.1 inch water gauge during an accident.
Containment Systems	3.8	The containment external pressure design has been changed from a 3 psi differential to a 5 psi differential pressure.
		The containment internal structure through liner anchors was eliminated.
		The containment dome liner has been increased from 3/8 inch thickness to 1/2 inch.
		The containment liner paint has been changed.

TABLE 1.3-2
DESIGN CHANGES SINCE PSAR SUBMITTAL

(Sheet 2 of 30)

(See Note 1)

Systems or Components	CPNPP/FSAR Section	Changes
	3.9	The break flow in the reactor cavity analysis is limited to 144 in^2 by pipe whip restraints instead of the previous 150 in^2. (See Section 3.9N.1.4.6 for application of leak-before-break to GDC-4.) Cathodic protection not required for containment liner, reinforced steel and other such steel encased in concrete. Containment penetration sleeves changed from A-333-70, Grade 6 to: 1. SA-333, Grade 6 for sleeve sizes 20 in. and smaller 2. SA-516, Grade 70 or SA-537, Class 2 to sleeve sizes 20 in. and larger Inside weld no longer utilized on cold pipe penetration. Sleeve with inside weld and guard pipe on hot pipe penetration replaced with sleeve without inside welds or guard pipe.
	3.11B	Maximum operational temperature increased to 120°F.
	6.2.1	The reactor cavity analysis was redone using new support criteria and restraint design.

TABLE 1.3-2
DESIGN CHANGES SINCE PSAR SUBMITTAL

(Sheet 3 of 30)

(See Note 1)

Systems or Components	CPNPP/FSAR Section	Changes
	6.2.4	Changes in signals used to actuate the containment isolation system to reflect changes in WNES protection system. Addition of bellows expansion joints to the valve isolation tanks.
	6.2.5	The containment liner paint has been changed from a primer and top coat that was zinc free to inorganic zinc as a primer in phenolic topcoat. The use of aluminum and zinc inside containment is now permitted. Remote thermal conductivity hydrogen analyzers are replaced by in-containment electrochemical sensors and microprocessor based analyzers located in the control room. The containment free volume has been changed from 2.9×10^6 cubic feet to 2.985×10^6 cubic feet
	6.5	Containment sump pH limits changed from 9.0 to 8.6 and 9.3 to 9.5.
Missile Shield	3.5	The CRDM roll away missile shield is constructed of steel instead of reinforced concrete.

TABLE 1.3-2
DESIGN CHANGES SINCE PSAR SUBMITTAL

(Sheet 4 of 30)

(See Note 1)

Systems or Components	CPNPP/FSAR Section	Changes
Safe Shutdown Impoundment	9.2.5	The presence of fractures in the SSI limestone foundation material was determined to be acceptable if the fractures occur above elevation 769.5 (spillway level), and if the fractures would not cause piping of core material. Clarification of the term “unweathered” to mean material that is firm, hard, and of appropriate strength parameters; the presence of slight oxidation resulting in some color change may not be an indication of weathering.
Shielding	12.1	Deleted the provisions for: 1. Local alarms at entries to Zone IV areas 2. Local and remote alarms at entries to Zone V areas has been deleted. The minimum density for ordinary concrete has been changed from 2.33 g/cc to 2.26 g/cc The secondary shield wall no longer surrounds the pressurizer and the thickness has been increased to 2 ft 9 in.
Tornado Characteristics	3.5	Tornado Missile Characteristics have been changed.

TABLE 1.3-2
DESIGN CHANGES SINCE PSAR SUBMITTAL

(Sheet 5 of 30)

(See Note 1)

Systems or Components	CPNPP/FSAR Section	Changes
Piping Systems, Handling Equipment and Tornado Venting Components	3.2 and Appendix 17A	Portions of systems or components are designed as Seismic Category II components.
Non-nuclear Safety Piping Systems or Components	3.2 and Appendix 17A	Portions of systems or components are designed as Class 5 components.
Auxiliary Feedwater System	3.6B	The system is identified as high energy fluid system.
II. Reactor Systems		
Fuel	4.2	The reactors are fueled with 17 x 17 fuel assemblies in lieu of 15 x 15 fuel assemblies.
Reactor internals	3.1, 7.7	The use of part length control rods has been removed from the CPNPP design.
	4.5.2	The reactor internals have been modified to accept 17 x 17 fuel assemblies.

TABLE 1.3-2
DESIGN CHANGES SINCE PSAR SUBMITTAL

(Sheet 6 of 30)

(See Note 1)

Systems or Components	CPNPP/FSAR Section	Changes
RCS pressure boundary	5.2	Flux core welding on stainless steel piping components fabricated in the shop are permitted. The allowable heat input range is 15 to 100 KJ/in. The use of the following as valve materials is now permitted for valves 2.5 in. and larger: bodies: SA 351 grade CF8 and CF8M bonnets: SA 351 grade CF8M with nickel plating or stellite hardfacing closure bolting: SA 564 Type 630 and SA 193 grade B6 closure nuts: SA 193 grade B6 and SA 194 grade 8M The use of the following as valve materials is now permitted for valves 2.0 in. and smaller: bodies: SA-351 Gr. CF8M SA-182 F 316

TABLE 1.3-2
DESIGN CHANGES SINCE PSAR SUBMITTAL

(Sheet 7 of 30)

(See Note 1)

Systems or Components	CPNPP/FSAR Section	Changes
		bonnets: SA-182 F 316 discs: A-567 Gr. 1 (Stellite 21) stems: SA-564 Type 416 (Non-pressure retaining applications) The lower heat input range limit for welding processes of austenitic stainless steel have been deleted, and the use of automatic gas tungsten arc-cold wire processes is allowed. The maximum allowable heat input for this process is 45 KJ/in.
	7.6	An RCS cold overpressure control system is employed to provide for the mitigation of potential cold overpressurization transients, utilizing existing power operated relief valves with modifications to their actuation logic.
Steam Generators	5.4.3	CPNPP utilizes model D5 steam generators in Unit 2. Thermal sleeves in reactor coolant loop branch nozzles have been deleted.
RHR systems	3.6	The RHR system is no longer identified as a high-energy fluid system located outside the containment.

TABLE 1.3-2
DESIGN CHANGES SINCE PSAR SUBMITTAL

(Sheet 8 of 30)

(See Note 1)

Systems or Components	CPNPP/FSAR Section	Changes
Safety Injection System	3.1	Change in SIS signal from coincident low pressurizer pressure and water level to low pressurizer pressure.
Reactor Coolant and Whip Restraint	3.1 3.6 3.9N 5.4	The leak-before-break technology has been applied to exclude from the design basis the dynamic effects of postulate ruptures in the reactor coolant loop piping.
III. Electrical Systems:		
Reactor Trip System	7.2	The reactor trip on low feedwater flow has been replaced by a low-low steam generator level trip. The RTD bypass line T hot and T cold measurements have been replaced by an N-16 power monitor and an inline T cold measurement CPNPP utilities 4 section power range neutron detector assemblies.
Engineered Safety Feature Systems	7.3	An improved steamline break protection system has been incorporated where safety injection and steamline isolation are initiated from low compensated steam line pressure.
CCW, SSW	7.3	Recirculation valves are now flow controlled, rather than pressure controlled

TABLE 1.3-2
DESIGN CHANGES SINCE PSAR SUBMITTAL

(Sheet 9 of 30)

(See Note 1)

Systems or Components	CPNPP/FSAR Section	Changes
Post-Accident Monitoring	7.5	SSW and CCW system parameters are not considered post-accident monitors
Hot Shutdown Panels	7.4	Indicators on the hot shutdown panel are no longer considered “Post accident monitors” and are treated as non-Class IE.
Electrical systems	8.1	Non-safety-related loads removed from Class 1E batteries and reassigned to ± 125-V non-Class 1E batteries. A static switch has been added to the BOP static uninterrupt. Power supply system inverter to accommodate the 120 V supply. 138 kV DeCordova line previously was directly fed from DeCordova substation. Now it is transferred through switching station located near DeCordova SES. Motor operated disconnect switch is added to the 138 kV line at CPNPP to isolate the startup transformer XST1 for maintenance. The condition of diesel generator trip on bus-fault is removed. Now diesel generator does not trip on bus fault condition. However, will trip on overspeed.

TABLE 1.3-2
DESIGN CHANGES SINCE PSAR SUBMITTAL

(Sheet 10 of 30)

(See Note 1)

Systems or Components	CPNPP/FSAR Section	Changes
		Some events which trip diesel generator excluding accident condition, are added and deleted as follows: 1. Bus fault signal to trip the generator breaker is deleted and following signal are included to trip the diesel generator. 2. Lube oil high temperature 3. Generator over current Diesel generator trips due to following events, during “no accident” conditions have been added 1. Generator Negative Sequence 2. Generator Ground 3. Generator Field Ground Trip Diesel generator rating modified from a 2000 hour rating to a 2 hour short term rating Plant computer removed from DC safeguards bus and added to 125/250 V bus. Both DC safeguard batteries are sized identically.

TABLE 1.3-2
DESIGN CHANGES SINCE PSAR SUBMITTAL

(Sheet 11 of 30)

(See Note 1)

Systems or Components	CPNPP/FSAR Section	Changes
		Back-up (Alternate) 120 V ac instrument power supply to the 118 V Class IE uninterruptible as bus is changed from 120 V single phase chassie emergency Lighting System to the 120 V ac supply from Class IE MCC via a 480/120 volt single phase Class 1E bypass transformer. Static switch is added in each BOP SUP system to allow automatic transfer from inverter to back-up (alternate) 120 V ac power source. The air circuit breakers are molded case type and fusible switches are provided on some switchboard feeders (instead of circuit breakers) for coordination purposes. Unit substation transformer was changed from 1500 kVA to 2000/1666 kVA. The backup supply for the 120-V NSSS instrument buses was originally taken from the 120-V single-phase emergency lighting system. These buses are now fed from the Class 1E motor control centers via a 480/120V single-phase Class 1E bypass transformer. Electric penetration centerline spacing changed from 2 ft 6 in. to 2 ft 2 in. Total integrated dose that electrical equipment is subjected to is increased to 2.0×10^8 rads (1.5 gamma and 0.5 beta).

TABLE 1.3-2
DESIGN CHANGES SINCE PSAR SUBMITTAL

(Sheet 12 of 30)

(See Note 1)

Systems or Components	CPNPP/FSAR Section	Changes
		Added ±24 volt dc system for the turbine generator systems
IV. Mechanical Water Systems:		
Component Cooling	9.2	The following equipment is no longer served by the CCWS: 1. Safety injection pump seal cooler 2. Centrifugal charging pump seal cooler 3. SGBS heat exchanger The following equipment is now served by the CCWS: 1. Instrument air aftercoolers 2. Chilled water system condensers 3. Control room air-conditioning condensers 4. Pump added for component cooling water drain tank in safeguards building 5. Control room alarm added if makeup water added to surge tank

TABLE 1.3-2
DESIGN CHANGES SINCE PSAR SUBMITTAL

(Sheet 13 of 30)

(See Note 1)

Systems or Components	CPNPP/FSAR Section	Changes
		The CCWS heat exchangers will utilize Cu-Ni tubes instead of stainless steel.
		Component Cooling Water pump normal supply temperature is increased to 115^{o}F.
Condensate Storage Facility	9.2.6	Storage capacity increased from 480,000 gallons to 500,000 gallons.
		Secondary system water storage decreased from 240,000 gallons to 224,000 gallons.
		Reserve auxiliary feedwater capacity increased from 240,000 gallons to 276,000 gallons.
Containment Spray System	3.2	Containment spray system nozzles will not bear an “N” stamp
		Change from one spray header to seven.
	6.5	Minimum spray fall height changed from 117 feet to 115 feet 9 inches.
		Eductor calibrated flow changed from 37.5 gpm to 45 gpm.
		Containment spray delivery lag time changed from 40 seconds to 60 seconds.

TABLE 1.3-2
DESIGN CHANGES SINCE PSAR SUBMITTAL

(Sheet 14 of 30)

(See Note 1)

Systems or Components	CPNPP/FSAR Section	Changes
		Containment sprayed volume changed from 2.528 x 10^6 cubic feet to 1.725 x 10^6 cubic feet. (From 87% to 57.8%)
Piping systems	3.6	The pipe whip analyses are now performed by the ANSYS computer program of Swanson Analysis System, Inc.
	3.9	The addition of stress limits for seismic Category I piping.
Potable and sanitary water system	9.2.4	Sewage plant effluent is discharged to Squaw Creek Reservoir instead of the evaporation ponds. Domestic water storage tank is designed to ASME B&PV Code Section III Code Class 3 requirements. Capacity of the sewage treatment plant is increased from 5000 gpd (normal operation) to 10,000 gpd (normal operation) and to 30,000 gpd during the construction stage. Capacity of the hypochlorinator has been increased.
Station Service Water System	9.2.1	The following changes have been made: 1. The SSI study resulted in an increase of the accident inlet temperature of the service water to 105°F

TABLE 1.3-2
DESIGN CHANGES SINCE PSAR SUBMITTAL

(Sheet 15 of 30)

(See Note 1)

Systems or Components	CPNPP/FSAR Section	Changes
		2. Revision of Service Water Intake structure
		3. Service water pump design temperature increased from 95°F to 120°F
		4. Traveling screen spray piping changed from carbon steel to copper alloy
		5. The SSWS no longer removes heat from the control room air-conditioning system
		6. The SSWS has been added as a backup water supply to the Auxiliary Feedwater System
		7. The non-safety-related train of the SSWS has been deleted
		8. Automatic strainers have been deleted.
		9. Piping is constructed of either stainless steel (or other corrosion resistant material) or is plasite 7122 lined carbon steel as indicated in the appropriate drawings and/or specifications.
Valves: Feedwater Isolation Valves	6.2.4	The feedwater isolation valve will no longer fail closed upon loss of power. Closure will be upon energizing redundant solenoid valves.

TABLE 1.3-2
DESIGN CHANGES SINCE PSAR SUBMITTAL

(Sheet 16 of 30)

(See Note 1)

Systems or Components	CPNPP/FSAR Section	Changes
Valves: General	3.1 6.2.4	Change from air-operated valves failing closed to air and solenoid-operated valves failing in the direction of greatest safety.
Materials	6.1B	The control of delta ferrite to reduce the susceptibility of stainless steel welds to hot cracking is no longer considered for ANS Safety Class 3 components. The requirement that the total leachable chloride and fluoride content of clean elastomers and plastics placed over all openings in components fabricated from austenitic stainless steel be limited to 15 and 10 ppm, respectively, has been deleted.
V. Fuel Storage and Handling Systems:		
Fuel storage and handling system	9.1	The following changes were made to the spent fuel storage handling system system: 1. An increase in total spent fuel storage space from 400 to 1166 spent fuel assemblies (1116 in spent fuel pools/25 in each Containment) 2. A decrease in center-to-center spacing from 21 to 16 in.

TABLE 1.3-2
DESIGN CHANGES SINCE PSAR SUBMITTAL

(Sheet 17 of 30)

(See Note 1)

Systems or Components	CPNPP/FSAR Section	Changes
		3. An increase in Keff from 0.90 to 0.95 for spent fuel assemblies if immersed in unborated water. Purification loop was added to the refueling cavity. The number of dry storage racks has been increased from 129 to 132. An increase in Keff from 0.90 to 0.98 for new fuel assemblies if flooded with unborated water. The dry cask loading concept is eliminated. The design of the spent fuel pool cooling heat exchangers is changed from horizontal to vertical.
VI. Auxiliary Systems:		
Auxiliary Feedwater System	9.2.1	The SSWS has been added as a backup water supply.
	10.4.9	Manually controlled heating systems have been changed to automatic systems The Auxiliary Feedwater is supplied to the secondary side of the steam generator through a separate upper Auxiliary Feedwater nozzle.

TABLE 1.3-2
DESIGN CHANGES SINCE PSAR SUBMITTAL

(Sheet 18 of 30)

(See Note 1)

Systems or Components	CPNPP/FSAR Section	Changes
Condensers	10.4.1	Design basis for auxiliary condensers was revised. Instrumentation for main condenser was modified to include high differential pressure alarm and temperature recorder in the control room. Isolation valves were added to the auxiliary condenser and turbine plant heat exchanger with change from a motor operator to a gear operator. The number of condensate pumps in the condenser hotwells has been changed from three to two half-capacity pumps.
Vacuum pumps	10.4.2	The number of mechanical vacuum pumps was changed from two to three. During startup, discharge is to the atmosphere; during normal operation, discharge is through the charcoal filter system.
Circulating water system	10.4.5	Design basis was revised. Pressure-differential alarm on the screen is annunciated in control room. Butterfly valves on the turbine plant cooling water heat exchangers were added. Circulating water pipes are made from coated carbon steel instead of concrete or plastic.

TABLE 1.3-2
DESIGN CHANGES SINCE PSAR SUBMITTAL

(Sheet 19 of 30)

(See Note 1)

Systems or Components	CPNPP/FSAR Section	Changes
Condensate Cleanup System	10.4.6	Backwash recovery and powdered resin handling added to system design
Feedwater heaters	10.4.7	Separate external drain coolers have been added to the 6A and 6B heaters.
Steam Generator Blowdown System	10.4.8	Treatment capacity of the system has been increased from 50 to 640 gpm.
		Blowdown cooled by condensate of condensate/blowdown instead of component cooling water
		Blowdown now recycled to heater drain tank at high temperature
		The processing of spent resin has been changed from regeneration to flushing into the storage tank prior to drumming.
		Change in bed processing as a result of elimination of the regeneration mode.
		SGBS heat exchanger has been changed from ANS Safety Class 3 to NNS.
Fire Protection System	9.5.1	The Fire Protection System has been completely upgraded to address current NRC Regulatory Positions.

TABLE 1.3-2
DESIGN CHANGES SINCE PSAR SUBMITTAL

(Sheet 20 of 30)

(See Note 1)

Systems or Components	CPNPP/FSAR Section	Changes
Lighting systems	9.5.3	Lighting system powered from localized motor control centers in lieu of a central power substation. Instrument room and primary plant egress routes have been added to the list of areas provided with DC emergency lighting. The AC Essential Lighting System and DC Emergency Lighting System are reclassified as non-Class 1E.
Diesel Generator Fuel Oil Day Tank	9.5.4	Fuel oil supply increased to 2160 gallons from 3 hours
The Diesel Generator Fuel Oil Storage and Transfer System	9.5.4	The diesel fuel oil storage tank is equipped with: 1. A fill line with a shutoff valve. 2. A perforated fill line which runs to within 2 feet of the bottom of the tank. 3. A dirt and water collector. 4. Hold down straps embedded in a concrete foundation. 5. A return line from the fuel oil day tank.

TABLE 1.3-2
DESIGN CHANGES SINCE PSAR SUBMITTAL

(Sheet 21 of 30)

(See Note 1)

Systems or Components	CPNPP/FSAR Section	Changes
Diesel Generator Combustion Air Intake and Exhaust System	9.5.8	Exhaust relief valve discharge changed to vertical.
Main Steam Supply System	10.2	Design temperature reduced to 541.5°F from 544.6°F.
		A vibration trip and alarm have been added.
		A MSR high level trip and alarm have been added.
	10.3	The main steam relief valves are relocated upstream from the safety valves to gain accessibility to these valves.
		The main steam isolation valve materials have been changed.
		Each steam line of auxiliary feedwater pump turbine is provided with an air-operated stop valve instead of motorized stop check valve.
		Phosphate was deleted from use and condensate polishing added.
		Design pressure changed to 1200 psig.
		Safety class piping extended to the first moment restraint beyond the Main Steam Stop Valves.

TABLE 1.3-2
DESIGN CHANGES SINCE PSAR SUBMITTAL

(Sheet 22 of 30)

(See Note 1)

Systems or Components	CPNPP/FSAR Section	Changes
		Power operated relief valves now set to open at 1130 psia.
		The Main Steam Stop Valve integral bypass valve has been upgraded to code Class 1 from Code Class 2
		Lowest and highest safety valve set pressures changed to 1185 and 1235 psig.
Steam Generators	10.3	Steam generator safety valves rated to pass 105 percent rather than 110 percent of flow.
Compressed Air System	9.3.1	Air accumulators are upgraded to ANS Safety class 3 and designed to ASME B&PV Code Section III Class 3 Requirements.
VII. Ventilation Systems:		
Containment Ventilation Systems	6.2.6	The hydrogen purge system filter efficiencies have been increased from 90 to 95%.
	9.4	CRDM cooling is accomplished by two 100-percent CRDM exhaust fans per containment instead of three 50-percent exhaust fans.
		The following changes have been made in the neutron detector well cooling system:

TABLE 1.3-2
DESIGN CHANGES SINCE PSAR SUBMITTAL

(Sheet 23 of 30)

(See Note 1)

Systems or Components	CPNPP/FSAR Section	Changes
		1. Use of chilled water instead of component cooling water as the cooling medium of the neutron detector well cooling system 2. A reduction in airflow from 24,000 ft^3 per containment to 13,100 ft^3 per containment for the neutron detector well cooling system due to the increase in the temperature gradient across the cooling coils Heating, ventilating, and air-conditioning (HVAC) dampers are manufactured in accordance with ANS Safety Class 3, 10 CFR Part 50 Appendix B, and manufacturers' standards rather than ASME II. To provide for adequate cooling during accident conditions, centrifugal chillers are used for the emergency fan coil units instead of service water. Increase size of containment coolers to absorb heat load from the CRDM. Only the containment purge exhaust ductwork is classified ANS Safety Class 3.
Other ventilation systems		
	9.4.1	Roof-mounted fans changed to in-duct fans for improved missile protection Reduction in outside air intake quantity for control room

TABLE 1.3-2
DESIGN CHANGES SINCE PSAR SUBMITTAL

(Sheet 24 of 30)

(See Note 1)

Systems or Components	CPNPP/FSAR Section	Changes
		Control room pressurization capacity increased from 150 cfm to 800 cfm.
		Control room air-conditioning units increased to 100 percent redundancy from 50 percent redundancy.
		Greater than 10 percent of the total air quantity is directed through the control room emergency filtration units.
		Four nuclear safety related vane-axial fans are utilized in each diesel generator room instead of one.
	9.4.1	The concept of lead system and standby system is deleted. Emergency recirculation will activate both Train A and Train B components.
	9.4.2	Auxiliary safeguards buildings ventilation supply distribution systems are now classified as seismic Category I
	9.4.3	Auxiliary building ventilation supply distribution system classified as seismic Category I
		Electrical area ventilation system contains only two 50-percent-capacity fans.

TABLE 1.3-2
DESIGN CHANGES SINCE PSAR SUBMITTAL

(Sheet 25 of 30)

(See Note 1)

Systems or Components	CPNPP/FSAR Section	Changes
		Uncontrolled access area ventilation system contains two 50-percent-capacity fans.
		Battery rooms have in-duct fans instead of roof-mounted fans.
		Office and service area ventilation systems have 50-percent redundancy; these systems are not required to satisfy the single-failure criterion and are nonessential to the safe shutdown of the reactor.
	General	Auxiliary, safeguards, fuel-handling, and containment purge supply and exhaust are incorporated into primary plant ventilation system.
		Summer design condition of diesel generator building changed from 104°F to 122°F
		Filter bed thickness increased from 2 inches to 4 inches.
		Air inlet design temperature to the hydrogen purge exhaust unit changed from 120°F to 250°F.
		Instrument air accumulators are now provided for the control room HVAC system.

TABLE 1.3-2
DESIGN CHANGES SINCE PSAR SUBMITTAL

(Sheet 26 of 30)

(See Note 1)

Systems or Components	CPNPP/FSAR Section	Changes
VIII. Steam & Power Conversion Systems:		
Component and sub-system design	5.4	The steam generators for Unit 2 have been changed from D4's to D5's
Steam and power conversion system	10.1	The steam dump system to the condenser form the steam generator system is not a safety-related feature included in the steam and power conversion system.
	10.3	The Main Steam Isolation Valve (MSIV) Bypass Valve were converted form automatic to manual. The hydraulic actuactors were deleted and handwheels installed. The valves are capable of being locked in position.
Turbine-generator	10.2	Added Occupational Safety and Health Act (OSHA) to codes and standards. The worst case accident, a failure of the cast stage of the low pressure turbine rotor, is analyzed. The following have been added to the list of events that initiate a turbine trip: 1. Reactor trip 2. Steam generator high-high level

TABLE 1.3-2
DESIGN CHANGES SINCE PSAR SUBMITTAL

(Sheet 27 of 30)

(See Note 1)

Systems or Components	CPNPP/FSAR Section	Changes
		3. Safety injection 4. Generator trip 5. Moisture separator high level (each MSR) 6. Excessive vibration during speed operation from 900 rpm until unit is synchronized. The following have been deleted from the list of events that initiate a turbine trip 1. Low flow of stator coolant The following have been added to the list of events that initiate a generator trip: 1. Loss of lube oil pressure 2. Low flow of stator coolant

TABLE 1.3-2
DESIGN CHANGES SINCE PSAR SUBMITTAL

(Sheet 28 of 30)

(See Note 1)

Systems or Components	CPNPP/FSAR Section	Changes
IX. Waste Processing Systems:		
Liquid Waste Processing System	11.2	The following equipment has been added to the LWPS: 1. Laundry reverse osmosis system 2. Laundry holdup and monitor tanks 3. Laundry holdup and monitor tank pump 4. 10,000 gallon floor drain tank 2 5. 30,000 gallon floor drain tank 3
Solid Waste Processing System (SWPS)	11.4	Utilizes an ATCOR proprietary cement solidification system per ATCOR Topical Report No. ATC-132A.
X. Sampling & Monitoring Systems:		
Process Sampling System	9.3.2	Phosphate analyzers replaced by sodium ion analyzers. System changed to non-nuclear safety related and non-seismic down-stream from the external containment isolation valves.
	9.3.2, II.B.3	Inclusion of Post Accident Sampling System.

TABLE 1.3-2
DESIGN CHANGES SINCE PSAR SUBMITTAL

(Sheet 29 of 30)

(See Note 1)

Systems or Components	CPNPP/FSAR Section	Changes
Containment Hydrogen Monitoring System	6.2.5	Remote thermal conductivity analyzers replaced by in-containment electrochemical sensors and microprocessor-based analyzers located in the control room.
Steam generator liquid sample monitors	11.5.2	Steam generator liquid sample monitors reduced from four to one to simplify design
Radiation Monitoring System	11.5	Changed from Analog to digital, microprocessor based system. Process monitors have been added to liquid waste processing and auxiliary condensate systems and to safeguards, auxiliary and fuel building vent ducts. Area monitors have been added to the fuel building to form a criticality alarm system. The auxiliary vent stack is no longer capable of being monitored by the containment air monitor Radiation monitors have been modified and have been added for accident monitoring.
	12.32	Change from analog system to digital microprocessor based system Radiation monitors have been added for accident monitoring.

XI.	Boron Recycle and Radioactive Waste Processing Systems		
1.	Boron Recycle	3.2	The code, code class, safety class, and seismic classification Table 17A-1 of system components were revised.
2.	Liquid Waste Processing System	3.2 Table 17A-1 Appendix 1A(B)	Same as for XI, item 1.
3.	Gaseous Waste Processing System	3.2 Table 17A-1 Appendix 1A(B)	Same as for XI, item 1.

NOTE 1: The FSAR is complete and does not rely on information contained in the PSAR. The original intent of this table was to provide a comparison with the PSAR when the FSAR was initially submitted for NRC Staff review. The information in this table is considered historical and will not be updated.

1.4 IDENTIFICATION OF AGENTS AND CONTRACTORS

1.4.1 OWNER AND OPERATORS

Vistra Operations Company LLC (Vistra OpCo) (operator) and Comanche Peak Power Company LLC (CP PowerCo) (owner) are subsidiaries of Vistra Corp. A simplified organizational diagram is shown in Figure 13.1-1.

1.4.2 CONTRACTORS

Vistra OpCo is responsible for the design and construction of CPNPP.

A historical list of major contractors during the design and construction of CPNPP is provided below.

- Gibbs & Hill, Inc. – original architect-engineer responsible for the design and engineering
- Stone and Webster Engineering Corporation (SWEC) – various engineering services
- Impell – various engineering services (e.g., fire protection, equipment qualification, cable tray hangers, conduit supports, startup assistance)
- Ebasco – various engineering services (e.g, HVAC, conduit supports, cable tray hangers, system interaction program)
- Westinghouse Electric Corporation – Nuclear Steam Supply System Manufacturer
- Dames & Moore – earth sciences engineer
- Brown & Root, Inc. – constructor
- Mason-Johnson & Associates – subsurface and soils investigation
- Freese and Nichols – reservoir design
- EDS Nuclear Incorporated – retained as a consultant for QA services to assist in the development of QA programs and to provide operations administrative support services

Responsibilities of the quality assurance program (e.g., audits, procurement) are described in Chapter 17.

TABLE 1.4-1
DELETED

1.5 REQUIREMENTS FOR FURTHER TECHNICAL INFORMATION

The activities described in Section 1.5 will be maintained as historical information and will not be updated.

Reference [1] presents descriptions of the safety-related research and development programs which are being carried out for, or by, or in conjunction with, Westinghouse Nuclear Energy Systems, and which are applicable to Westinghouse Pressurized Water Reactors (PWRs).

For each program still in progress the safety-related program is first introduced, followed, where appropriate, by background information. There is, then, a description of the program which relates the program objectives to the problem and presents pertinent recent results. Finally, a back up position may be given for programs (generally experimental rather than analytical) which have not yet reached a stage where it is reasonably certain that the results confirm the expectation. The back up position is one that might be used if the results are unfavorable; it is not necessarily the only course that might be taken.

The term “research and development”, as used in this report, is the same as that used by the NRC in 10CFR50.2, that is:

(n) ‘Research and development’ means (1) theoretical analysis, exploration or experimentation; or (2) the extension of investigative findings and theories of a scientific nature into practical application for experimental and demonstration purposes including the experimental production and testing of models, devices, equipment, materials, and processes.

The technical information generated by these research and development programs will be used either to demonstrate the safety of the design and more sharply define margins of conservatism, or will lead to design improvements.

1.5.1 BLOWDOWN HEAT TRANSFER TESTING

The Nuclear Regulatory Commission (NRC) acceptance criteria for Emergency Core Cooling Systems (ECCS) for light-water power reactors was issued in Section 50.46 of 10CFR50 on December 28, 1973. It defines the basis and conservative assumptions to be used in the evaluation of the performance of the ECCS. Westinghouse believes that some of the conservatism of the criteria is associated with the manner in which transient departure from nucleate boiling (DNB) phenomena are treated in the evaluation models. Transient critical heat flux data presented at the 1972 specialists meeting of the Committee on Reactor Safety Technology (CREST) indicated that the time to DNB can be delayed under transient conditions. To demonstrate the conservatism of the ECCS evaluation models, Westinghouse initiated a program to experimentally simulate the blowdown phase of a loss of coolant accident (LOCA). This testing is part of the Electric Power Research Institute (EPRI) sponsored Blowdown Heat Transfer Program, which was started early in 1976. Testing was completed in 1979. A DNB correlation will be developed by Westinghouse from these test results for use in the ECCS analyses.

1.5.1.1 Objective

The objective of the Blowdown Heat Transfer Test was to determine the time that DNB occurs under LOCA conditions. This information will be used to confirm the existing, or develop a new

Westinghouse transient DNB correlation. The steady state DNB data obtained from 15 x 15 and 17 x 17 test programs can be used to assure that the geometrical differences between the two fuel arrays can be correctly treated in the transient correlations.

1.5.1.2 Program

The program was divided into two phases. The Phase I tests started from steady state conditions, with sufficient power to maintain nucleate boiling throughout the bundle. Controlled ramps of decreasing test section pressure or flow initiated DNB. By applying a series of controlled conditions, investigation of the DNB was studied over a range of qualities and flows, and at pressures relevant to a PWR blowdown.

Phase I provided separate-effects data to permit heat transfer correlation development.

Typical parameters used for Phase I testing are shown in Table 1.5-1.

Phase II simulates PWR behavior during a LOCA to permit definition of the time delay associated with onset of DNB. Tests in this phase covered the large double ended guillotine cold leg break. All tests in Phase II were also started after establishment of typical steady state operating conditions. The fluid transient was then initiated, and the rod power decay programmed in such a manner as to simulate the actual heat input of fuel rods. The test was terminated when the heater rod temperatures reach a predetermined limit.

Typical parameters used for Phase II testing are shown in Table 1.5-2.

1.5.1.3 Test Description

The experimental program was conducted in the J-Loop at the Westinghouse Forest Hills Facility with a full length 5 x 5 rod bundle simulating a section of a 15 x 15 assembly to determine DNB occurrence under LOCA conditions.

The heater rod bundles used in this program were internally-heated rods, capable of a maximum power of 18.8 kW/ft, with a total power of 135 kW (for extended periods) over the 12 foot heated length of the rod. Heat was generated internally by means of a varying cross-sectional resistor which approximates a chopped cosine power distribution. Each rod was adequately instrumented with a total of 12 clad thermocouples.

1.5.1.4 Results

The experiments in the DDNB Facility resulted in cladding temperature and fluid properties measured as a function of time throughout the blowdown range from 0 to 20 seconds.

Facility modifications and installation of the initial test bundle were completed. A series of shakedown tests in the J-Loop were performed. These tests provided data for instrumentation calibration and check-out, and provided information regarding facility control and performance. Initial program tests were performed during the first half of 1975. Under the sponsorship of EPRI, testing was reinitiated during 1976 on the same test bundle. The testing was terminated in November and plans were made for a new test bundle and further testing during 1978-79. These tests were completed in December of 1979. A DNB correlation will be developed from these test results for use in the Westinghouse ECCS analyses.

TABLE 1.5-1
DELAYED DEPARTURE FROM NUCLEATE BOILING PHASE I TEST PARAMETERS

Parameters	Nominal Value
Initial Steady State Conditions	
Pressure	1250 to 2250 psia
Test section mass velocity	12 to 2.5 x 10^6 lb/hr-ft^2
Core inlet temperature	550 to 600°F
Maximum heat flux	306,000 to 531,000 Btu/hr-ft^2
Transient Ramp Conditions	
Pressure decrease	0 to 350 psi/sec and subcooled depressurization from 2250 psia
Flow decrease	0 to 100%/sec
Inlet enthalpy	Constant

TABLE 1.5-2
DELAYED DEPARTURE FROM NUCLEATE BOILING PHASE II TEST PARAMETERS

Parameters	Nominal Value
Initial Steady State Conditions	
Pressure	2250 psia
Test section mass velocity	2.5×10^6 lb/hr-ft^2
Inlet temperature	545°F
Maximum heat flux	531,000 Btu/hr-ft^2
Transient Conditions	
Simulated break	Double ended cold leg guillotine breaks

1.6 MATERIAL INCORPORATED BY REFERENCE

Table 1.6-1 lists documents which provide information additional to that provided in this FSAR and have been filed separately with the Nuclear Regulatory Commission (NRC) in support of the CPNPP operating licenses. A change to any of the documents listed in this table is considered to be a change to the FSAR and is subject to the same processing requirements. It should be noted, however, that for documents with revisions and/or dates, only the specific revisions and/or dates listed are considered to be part of the FSAR. Later revisions to these documents are not part of the FSAR unless they are incorporated into this table (except for the Technical Requirements Manual (including TRM Bases) and Technical Specifications Bases).

Table 1.6-2 lists many of the topical reports and other licensing documents which were provided to the NRC in support of the CPNPP operating licenses as additional background and/or reference material for the FSAR. Material in this table is not considered to be "incorporated by reference" and changes to these documents are not considered to changes to the FSAR. Table 1.6-2 is historical and is not updated.

Documents listed in Table 1.6-2 (or are referenced elsewhere in the FSAR but are not listed in Table 1.6-1) are provided for information (e.g., references listed at the end of each FSAR section) or are documents to which CPNPP is committed (e.g., Regulatory Guides, Codes and Standards). Compliance with committed documents is required but the documents are not considered to be part of the FSAR.

1.7 ELECTRICAL, INSTRUMENTATION, AND CONTROL DRAWINGS

A list of electrical, instrumentation, and control drawings is presented in Tables 1.7-1 and 1.7-2 for Unit 1 and Unit 2, respectively. These drawings include safety-related systems and non-safety-related systems which interact with the safety-related systems.

The fifth digit letter of the drawing number indicates type of drawing. E indicates Electrical drawing and M indicates Mechanical Instrumentation and Control (I&C) drawing.

The sixth digit numeral indicates Unit number. 1 indicates Unit 1 and 2 indicates Unit 2.

The revision and date indicated identify the drawing issue submitted to the NRC staff for review. Additional drawings or later revisions of these drawings will be provided upon request and the latest revision of all drawings are available for review on site.

APPENDIX 1A(N) - DISCUSSION OF REGULATORY GUIDES

This appendix discusses the CPNPP positions on, and compliance with, Division 1 regulatory guides as they apply to the Nuclear Steam Supply System scope of equipment and services. Appendix 1A(B) is provided separately for the balance of plant information.

Identification of specific issues of regulatory guides are provided in the discussions where appropriate.

Regulatory Guide 1.1

Net Positive Suction Head for Emergency Core Cooling and Containment Heat Removal System Pumps

Discussion

CPNPP complies with Safety Guide 1 (11/2/70) as discussed in Section 6.3.2.2.10.

Also refer to Appendix 1A(B) for further discussion.

Regulatory Guide 1.2

Thermal Shock to Reactor Pressure Vessels

Discussion

CPNPP follows all the recommendations of Safety Guide 2 (11/20/70). Regulatory Position C.1 is followed by Westinghouse's own analytical and experimental programs as well as by participation in the Heavy Section Steel Technology (HSST) program at the Oak Ridge National Laboratory.

Analytical techniques have been developed by Westinghouse to perform fracture evaluations of reactor vessels under thermal shock loadings.

Under the HSST program a number of 6 inch thick 39 inch outside diameter steel pressure vessels containing carefully prepared and sharpened surface cracks are being tested. Test conditions include both hydraulic internal pressure loadings and thermal shock loadings. The objective of this program is the validate analytical fracture mechanics techniques and demonstrate quantitatively the margin of safety inherent in reactor pressure vessels.

A number of vessels have been tested under hydraulic pressure loadings, and results have confirmed the validity of fracture analysis techniques. The results and implications of the hydraulic pressure tests are summarized in Oak Ridge National Laboratory report ORNL-TM-5090.

Three thermal shock experiments have been completed and are now being evaluated. Preliminary information indicates that the analytical techniques do agree favorably with experimental results.

Westinghouse is continuing to obtain fracture toughness data for reactor pressure vessel steels through internally funded programs as well as HSST sponsored work.

Fracture toughness testing of irradiated compact tension fracture toughness specimens has been completed. The complete post-irradiation data on 0.394, 2, and 4 inch thick specimens are now available from the HSST program. Both static and dynamic post-irradiation fracture toughness data have been obtained. Evaluation of the data obtained to date on material irradiated to fluences between 2.2 and 4.5 10^{19} n/cm^2 indicates that the reference toughness curve as contained in the American Society of Mechanical Engineers (ASME) Code, Section III, remains a conservative lower bound for toughness values for pressure vessel steels. Another fracture toughness program is now underway. This program involves the irradiation and testing of weld metal used in fabrication of operating pressure vessels of pre-1972 construction. These welds characteristically have high copper contents and low initial Charpy V-notch “shelf” energies. Results of this program are expected in 1977.

Details of progress and results obtained in the HSST program are available in the HSST program semiannual (quarterly beginning in 1974) progress reports, issued by Oak Ridge National Laboratory.

Regulatory Position C.2 is followed inasmuch as no significant changes have been made in approved core or reactor designs.

Regulatory Position C.3 is followed since the vessel design does not preclude the use of an engineering solution to assure adequate recovery of the fracture toughness properties of the vessel material.

If additional margin is needed, the reactor vessel can be annealed at any point in its service life. This solution is already feasible, in principle, and could be performed with the vessel in place.

Regulatory Guide 1.3

Assumptions Used for Evaluating the Potential Radiological Consequences of a Loss of Coolant Accident for Boiling Water Reactors

Discussion

This regulatory guide is not applicable to the Comanche Peak Nuclear Power Plant (CPNPP).

Regulatory Guide 1.4

Assumptions Used for Evaluating the Potential Radiological Consequences of a Loss of Coolant Accident for Pressurized Water Reactors

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.5

Assumptions Used for Evaluating Potential Radiological Consequences of a Steam Line Break Accident for Boiling Water Reactors

Discussion

This regulatory guide is not applicable to the CPNPP.

Regulatory Guide 1.6

Independence Between Redundant Standby (Onsite) Power Sources and Between Their Distribution Systems

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.7

Control of Combustible Gas Concentrations in Containment Following a Loss of Coolant Accident

Discussion

Based on a revision to 10CFR50.44, Regulatory Guide 1.7 no longer applies to CPNPP. See Section 6.2.5.

Regulatory Guide 1.8

Personnel Selection and Training

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.9

Selection of Diesel Generator Set Capacity for Standby Power Supplies

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.10

Mechanical (Cadweld) Splices in Reinforcing Bars of Category I Concrete Structures

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.11

Instrument Lines Penetrating Primary Reactor Containment

Discussion

CPNPP meets the recommendations of Safety Guide 11 (3/10/71) in accordance with the comments of Section 7.3.1.1.2.

Also refer to Appendix 1A(B) for further discussion.

Regulatory Guide 1.12

Instrumentation for Earthquakes

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.13

Spent Fuel Storage Facility Design Basis

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.14

Reactor Coolant Pump Flywheel Integrity

Discussion

The CPNPP design follows the recommendations of Revision 1 (8/75) of Regulatory Guide 1.14 except for the following:

1. Post-spin inspection

   Westinghouse has shown in Reference [4] that the flywheel would not fail at 290 percent of normal speed for a flywheel flaw of 1.15 inches or less in length. Results for a double ended guillotine break at the pump discharge with full separation of pipe ends assumed, show the maximum overspeed was to be less than 100 percent of normal speed. The maximum overspeed was calculated in Reference [4] to be about 280 percent of normal speed for the same postulated break, and an assumed instantaneous loss of power to the reactor coolant pump. In comparison with the overspeed presented above, the flywheel is tested at 125 percent of normal speed. Thus, the flywheel could withstand a speed up

to 2.3 times greater than the flywheel spin test speed 125 percent provided that no flaws greater than 1.15 inches are present. If the maximum speed were 125 percent of normal speed or less, the critical flaw size for failure would exceed 6 inches in length.

Nondestructive tests and critical dimension examinations are all performed before the spin tests. The inspection methods employed (described in Reference [4] provide assurance that flaws significantly smaller than the critical flaw size of 1.15 inches for 290 percent of normal speed would be detected. Flaws in the flywheel will be recorded in the pre-spin inspection program (see Reference [4]). Flaw growth attributable to the spin test (i.e., from a single reversal of stress, up to speed and back), under the most adverse conditions, is about three orders of magnitude smaller than what nondestructive inspection techniques are capable of detecting. For these reasons, Westinghouse performs no post- spin inspections and believes that pre-spin test inspections are adequate.

2. Interference fit stresses and excessive deformation

Much of Revision 1 to Regulatory Guide 1.14 deals with stresses in the flywheel resulting from the interference fit between the flywheel and the shaft. Because Westinghouse's design specifies a light interference fit between the flywheel and the shaft; at zero speed, the hoop stresses and radial stresses at the flywheel bore are negligible. Centering of the flywheel relative to the shaft is accomplished by means of keys and/or centering devices attached to the shaft, and at normal speed, the flywheel is not in contact with the shaft in the sense intended by Revision 1. Hence, the definition of "Excessive Deformation," as defined in Revision 1 of Regulatory Guide 1.14, is not applicable to the Westinghouse design since the enlargement of the bore and subsequent partial separation of the flywheel from the shaft does not cause unbalance of the flywheel. Extensive Westinghouse experience with reactor coolant pump flywheels installed in this fashion has verified the adequacy of the design.

Westinghouse's position is that combined primary stress levels, as defined in Revision 0 of Safety Guide 14 (C.2.a and C.2.c), are both conservative and proven and that no changes to these stress levels are necessary. Westinghouse designs to these stress limits and thus does not have permanent distortion of the flywheel bore at normal or spin test conditions.

3. Discussion B, cross rolling ratio of 1 to 3

Westinghouse's position is that specification of a cross rolling ratio is necessary since past evaluations have shown that ASME SA-533 Grade B Class 1 materials produced without this requirement have suitable toughness for typical flywheel applications. Proper material selection and specification of minimum material properties in the transverse direction adequately ensure flywheel integrity. An attempt to gain isotropy in the flywheel material by means of cross rolling is unnecessary since adequate margins of safety are provided by both flywheel material selection (ASME SA-533 Grade B Class 1) and by specifying minimum yield and tensile levels and toughness test values taken in the direction perpendicular to the maximum working direction of the material.

4. Regulatory Position C.1.a, relative to vacuum-melting and degassing process of the electroslag process

   The requirements for vacuum melting and degassing process or the electroslag process are not essential in meeting the balance of the Regulatory Position nor do they, in themselves, ensure compliance with the overall Regulatory Position. The initial Safety Guide 14 (10/27/71) stated that the "flywheel material should be produced by process that minimized flaws in the material and improves its fracture toughness properties." This is accomplished by using SA-533 material including vacuum treatment.

5. Regulatory Position C.2.b

   Westinghouse suggests that this paragraph be reworded as follows in order to remove the ambiguity of reference to an undefined overspeed transient.

   "Design speed should be 125 percent of normal speed or the speed to which the pump motor might be electrically driven by station turbine generator during anticipated transients, whichever is greater. Normal speed is defined as the synchronous speed of the alternating current drive motor at 60 hertz."

6. Inspection

   The reactor coolant pump flywheel inspection is in accordance with Technical Specification 5.5.7.

Regulatory Guide 1.15

Testing of Reinforcing Bars for Category I Concrete Structures

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.16

Reporting of Operating Information - Appendix A Technical Specifications

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.17

Protection of Nuclear Power Plants Against Industrial Sabotage

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.18

Structural Acceptance Test for Concrete Primary Reactor Containments

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.19

Nondestructive Examination of Primary Containment Liner Welds

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.20

Comprehensive Vibration Assessment Program for Reactor Internals During Preoperational and Initial Startup Testing

Discussion

The CPNPP position on Revision 2 (5/76) of Regulatory Guide 1.20 is discussed in Section 3.9N.2.4.

Regulatory Guide 1.21

Measuring, Evaluating, and Reporting Radioactivity in Solid Wastes and Releases of Radioactive Materials in Liquid and Gaseous Effluents from Light-Water-Cooled Nuclear Power Plants

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.22

Periodic Testing of Protection System Actuation Functions

Discussion

CPNPP meets the recommendations of Safety Guide 22 (2/17/72) in accordance with the comments of Section 7.1.2.5.

Regulatory Guide 1.23

Onsite Meteorological Program

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.24

Assumptions Used for Evaluating the Potential Radiological Consequences of a Pressurized Water Reactor Radioactive Gas Storage Tank Failure

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.25

Assumptions Used for Evaluating the Potential Radiological Consequences of a Fuel Handling Accident in the Fuel Handling and Storage Facility for Boiling and Pressurized Water Reactors

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.26

Quality Group Classifications and Standards for Water, Steam and Radioactive-Waste-Containing Components of Nuclear Power Plants

Discussion

Quality group classification of fluid system equipment of the Westinghouse scope of supply for the CPNPP is as described in Section 3.2.

Nuclear Steam Supply System fluid system components important to safety are classified in accordance with the August 1970 Draft of American National Standard (ANSI) N18.2, “Nuclear Safety Criteria for the Design of Stationary Pressurized Water Reactor Plant,” except for the deviation described in Section 3.2.2. In addition, components of the accumulator subsystem and the refueling water subsystem are placed in a higher classification. The effect of this higher classification is to produce the same quality levels for all components as is achieved by the application of the 1973 version of N18.2, as finally accepted by ANSI.

Classification by this means is an alternate acceptable method of meeting the intent of Revision 3 (2/76) of Regulatory Guide 1.26. The method of classifying is in accordance with NRC stated policy on regulatory guides that “methods and solutions different from those set out in the guides will be acceptable if they provide a basis for the findings requisite to the issuance or continuance of a permit or license by the Commission.”

Also refer to Appendix 1A(B) for further discussion.

Regulatory Guide 1.27

Ultimate Heat Sink for Nuclear Power Plants

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.28

Quality Assurance Program Requirements (Design and Construction)

Discussion

The Westinghouse quality assurance program, including the Westinghouse position on Regulatory Guide 1.28, is presented in WCAP-8370 [5].

Also refer to Appendix 1A(B) for further discussion.

Regulatory Guide 1.29

Seismic Design Classification

Discussion

Seismic classification of fluid system equipment of Westinghouse scope of supply for the CPNPP is as described in Section 3.2.

The classification of components by safety class provides the means of establishing applicable aseismic design requirements of both components and system. At the time the CPNPP was designed, duplication by special seismic classification was unnecessary since ANSI N18.2, "Nuclear Safety Criteria for the Design of Stationary Pressurized Water Reactor Plants" was considered to establish seismic design requirements of systems having components classified as Safety Class 1, Safety Class 2, or Safety Class 3. Safety class fluid system components are designed to remain functional in the event of occurrence of the Design Basis Earthquake, defined in Section 2.1.5.4 of ANSI N18.2-1973 but now identified as the Safe Shutdown Earthquake by the NRC. The Reactor Protection System includes similar aseismic design features.

Classification by this means is an alternate acceptable method of meeting the intent of Revision 2 (2/76) of Regulatory Guide 1.29. The method of classifying is in accordance with NRC stated policy on regulatory guides that "methods and solutions different from those set out in the guides will be acceptable if they provide a basis for the findings requisite to the issuance or continuance of a permit or license by the Commission."

Also refer to Appendix 1A(B).

Regulatory Guide 1.30

Quality Assurance Requirements for the Installation, Inspection, and Testing of Instrumentation and Electric Equipment

Discussion

The design criteria Westinghouse applies to safety-related instrumentation and controls are consistent with ANSI N45.2.4-1972 (IEEE Standard 336-1971), “Installation, Inspection, and Testing Requirements of Instrumentation and Electrical Equipment During the Construction of Nuclear Power Generating Stations.” The major actions is complying with this standard fall within the scope of plant construction. Westinghouse functions in design and procurement of instrumentation and electrical equipment are supportive to the later fulfillment of the standard at the time of construction.

For those activities performed after September 1, 1972, Westinghouse follows the guidance of Safety Guide 30 (8/11/72). For those activities performed prior to September 1, 1972, the quality assurance procedures employed in the design of the CPNPP may vary in detail from the position of the regulatory guide, but meet its essential requirements.

Also refer to Appendix 1A(B).

Regulatory Guide 1.31

Control of Stainless Steel Welding

Discussion

The Westinghouse position concerning the control of delta ferrite in stainless steel welding is discussed in Section 5.2.3. The Westinghouse production weld verification program, as described in Reference [6], was approved as a satisfactory substitute for conformance with the NRC Interim Position on Revision 3 (4/78) of Regulatory Guide 1.31. The results of the verification program have been summarized and documented in Reference [7].

The welding of austenitic stainless steel is controlled to mitigate the occurrence of microfissuring or hot cracking in the weld. Although published data and experience have not confirmed that fissuring is detrimental to the quality of the weld, it is recognized that such fissuring is undesirable in a general sense. Also, it has been well documented in the technical literature that the presence of delta ferrite is one of the mechanisms for reducing the susceptibility of stainless steel welds to hot cracking. However, there are insufficient data to specify a minimum delta ferrite level below which the material will be prone to hot cracking. It is assumed that such a minimum lies somewhere between 0 and 3 percent delta ferrite.

The scope of these controls discussed herein encompasses welding processes used to join stainless steel parts in components designed, fabricated or stamped in accordance with ASME B&PV Code, Section III Class 1, 2, 3 and CS components. Delta ferrite control is appropriate for the above welding requirements except in the following cases where no filler metal is used (for example, in electron beam welding and in autogenous gas shielded tungsten arc welding), where stainless steel filler metal is used for weld metal cladding, explosive welding, and welding using fully austenitic welding materials.

The fabrication and installation specifications require welding procedure and welder qualification in accordance with Section III, and include the delta ferrite determinations for the austenitic stainless steel welding materials that are used for welding qualification testing and for production processing. Specifically, the undiluted weld deposits of the “starting” welding materials are

required to contain a minimum of 5 percent delta ferrite[a] as determined by chemical analysis and calculation using the appropriate weld metal constitution diagrams in Section III. When new welding procedure qualification tests are evaluated for these applications, including repair welding of raw materials, they are performed in accordance with Section III and Section IX. The results of all the destructive and non-destructive tests are reported in the procedure qualification record in addition to the information required by Section III.

The "starting" welding materials used for fabrication and installation welds of austenitic stainless steel materials and components meet the requirements of Section III. The austenitic stainless steel welding material conforms to ASME weld metal analysis A-7 (designated A-8 in the 1974 Edition of the ASME code), type 308 or 308L for all applications. Bare weld filler metal, including consumable inserts, used in inert gas welding processes conform to ASME SFA-5.9, and are procured to contain not less than 5 percent delta ferrite in the deposit according to Section III. Weld filler metal materials used in flux shielded welding processes conform to ASME SFA-5.4 or SFA-5.9 and are procured in a wire-flux combination to be capable of providing not less than 5 percent delta ferrite in the deposit according to Section III. Welding materials are tested using the welding energy inputs to be employed in production welding.

Combinations of approved heats and lots of "starting" welding materials are used for all welding processes. The welding quality assurance program includes identification and control of welding material by lots and heats as appropriate. All of the weld processing is monitored according to approved inspection programs which include review of "starting" materials, qualification records and welding parameters. Welding systems are also subject to quality assurance audit including calibration of gages and instruments, identification of "starting" and completed materials, welder and procedure qualifications, availability and use of approved welding and heat treating procedures, and documentary evidence of compliance with materials, welding parameters, and inspection requirements. Fabrication and installation welds are inspected using non-destructive examination methods according to Section III rules.

To assure the reliability of these controls, Westinghouse has performed a delta ferrite verification program, described in Reference [6]. The verification program has been approved as a valid approach to verify the Westinghouse hypothesis and is considered an acceptable alternative for conformance with the Interim Position on Regulatory Guide 1.31. The Regulatory Staff's acceptance letter and topical report evaluation were received on December 30, 1974. The program results, which support the hypothesis presented in Reference [6], are summarized in Reference [7].

Welds made in accordance with the criteria discussed herein have continually resulted in sound production welds, which are free from detrimental fissuring and consistently conform to Section III non-destructive acceptance standards.

Also refer to Appendix 1A(B).

a. The equivalent Ferrite Number may be substituted for percent delta ferrite.

Regulatory Guide 1.32

Criteria for Safety-Related Electric Power Systems from Nuclear Power Plants

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.33

Quality Assurance Program Requirements (Operation)

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.34

Control of Electroslag Weld Properties

Discussion

Where electroslag welding is used in fabricating nuclear plant components the Westinghouse procurement procedure requires vendors to meet the guidelines of Regulatory Guide 1.34 (12/28/72).

Regulatory Guide 1.35

Inservice Inspection of Ungrouted Tendons in Prestressed Concrete Containment Structures

Discussion

This regulatory guide is not applicable to the CPNPP.

Regulatory Guide 1.36

Nonmetallic Thermal Insulation for Austenitic Stainless Steel

Discussion

The Westinghouse practice meets the recommendations of Regulatory Guide 1.36 (2/23/73) but is more stringent in several respects as discussed below.

The nonmetallic thermal insulation used on the reactor coolant pressure boundary is specified to be made of compounded materials which yield low leachable chloride and/or fluoride concentrations. The compounded materials in the form of blocks, boards, cloths, tapes, adhesives, cements, etc., are silicated to provide protection of austenitic stainless steels against stress corrosion which may result from accidental wetting of the insulation by spillage, minor leakage or other contamination from the environmental atmosphere. Each lot of insulation materials provides a compatible combination for the reactor coolant pressure boundary.

The tests for qualification specified by this regulatory guide (ASTM- C-692-71 or RDT M12-IT) allow use of the tested insulation materials if no more than one of the metallic test samples crack. Westinghouse rejects the tested insulation material if any of the test samples crack.

The Westinghouse procedure is more specific than the procedures suggested by this regulatory guide, in that the Westinghouse specification requires determination of leachable chloride and fluoride ions from a sample of the insulating material. The procedures in this regulatory guide (ASTM-D-512 and ASTM-D-1179) do not differentiate between leachable and unleachable halogen ions.

In addition, Westinghouse experience indicates that only one of the three methods allowed under ASTM-D-512 and ASTM-D-1179 for chloride and fluoride analysis is sufficiently accurate for reactor applications. This is the “referee” method, which is used by Westinghouse. These requirements are defined in Westinghouse Process Specification PS-83336KA.

Also refer to Appendix 1A(B).

Regulatory Guide 1.37

Quality Assurance Requirements for Cleaning of Fluid Systems and Associated Components of Water-Cooled Nuclear Power Plants

Discussion

This guide (dated March 16, 1973) endorses ANSI N45.2.1-1973, which applies to cleaning procedures at the construction site and is therefore not in the Westinghouse scope. Westinghouse procurement orders apply cleaning requirements during fabrication and packaging of safety-related components so that NSSS equipment is delivered to the site in a properly cleaned condition. A Westinghouse process specification provides detailed cleaning requirements for equipment manufacturers, and is included as a procurement requirement, where appropriate.

Also refer to Appendix 1A(B).

Regulatory Guide 1.38

Quality Assurance Requirements for Packaging, Shipping, Receiving, Storage, and Handling of Items for Water-Cooled Nuclear Power Plants

Discussion

For the CPNPP whose application was docketed prior to April 1, 1973, the quality assurance procedures employed in the design and construction phases may vary in detail from the current position of Revision 1 (10/76) of the regulatory guide but meet its essential requirements in that they follow good business practices as defined in the applicable Westinghouse process specifications.

For activities initiated after January 1, 1975, for the CPNPP, Reference [5] is applicable. This plan follows the guidance of ANSI N45.2.2-1978 (Unit 1) ANSI N45.2.2-1972 (Unit 2) (which is recognized by Regulatory Guide 1.38) in the design, procurement, fabrication and shipment of

safety-related NSSS equipment. Measures are applied, as appropriate, to apply packaging requirements to procurement orders, to review supplier packaging procedures, to apply proper cleaning requirements, to apply proper marking and identification, to provide protection to equipment from physical or weather damage, to apply special handling precautions and to define storage requirements. A Westinghouse process specification incorporates detailed packaging and handling requirements for equipment manufacturers, and is included as a procurement requirement where appropriate.

Regulatory Guide 1.39

Housekeeping Requirements for Water-Cooled Nuclear Power Plants

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.40

Qualification Tests of Continuous-Duty Motors Installed Inside the Containment of Water-Cooled Nuclear Power Plants

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.41

Preoperational Testing of Redundant On-Site Electric Power Systems to Verify Proper Load Group Assignments

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.42

Interim Licensing Policy on As Low As Practicable for Gaseous Radioiodine Releases from Light-Water-Cooled Nuclear Power Reactors

Discussion

This regulatory guide was withdrawn March 22, 1976.

Regulatory Guide 1.43

Control of Stainless Steel Weld Cladding of Low-Alloy Steel Components

Discussion

The reactor vessel bottom head (Unit 1) and heads (Unit 2), shell courses, and torus sections were constructed of SA-533, Grade B, Class 1, plate material made to a fine grain practice. This material was clad by the shielded metal arc, one-wire submerged arc, and the 4-inch strip submerged arc processes; the shielded metal arc and one-wire submerged arc processes are considered to be low heat input methods of cladding.

Although the plate material is SA-533, Grade B, Class 1, made to fine grain practice and not subject to qualification restrictions by Regulatory Guide 1.43 (5/73), the 4-inch strip clad process was qualified.

1. Unit 1

   The shielded metal arc and the one-wire submerged arc processes (both considered low heat input) were used to clad the vessel flanges and the closure head, which was forged of SA-508, Class 3. These processes were also used to clad the primary nozzles which were constructed of SA-508, Class 2, forging material.

2. Unit 2

   The shielded metal arc and the one-wire submerged arc processes (both considered low heat input) were used to clad the closure head and vessel flanges and the primary nozzles which were constructed of SA-508, Class 2, forging material.

The reactor vessel fabricator monitors and records the weld parameters to verify conformance with the parameters established by the procedure qualification as recommended by Regulatory Position C.3.

Consequently, the reactor vessel is in full compliance with Regulatory Guide 1.43.

The Unit 1 steam generator parts which are clad are constructed of SA-508, Grade 3a steel. The Unit 2 steam generator and pressurizer parts which are clad are constructed of SA-533, Grade A, Class 2, and SA-508, Class 2, steels. These materials are made to fine grain practices and all welding is done with low heat input techniques.

Regulatory Guide 1.44

Control of the Use of Sensitized Stainless Steel

Discussion

The Westinghouse position on Regulatory Guide 1.44 (5/73) is discussed in part in Section 5.2.3.4.

Westinghouse compliance with the separate positions of the guide are as follows:

The use of processing, packaging and shipping controls, and preoperational cleaning to preclude adverse effects of exposure to contaminants on all stainless steel materials are in accordance with Regulatory Position C.1.

Austenitic stainless steel starting materials are utilized in the final heat treated conditions required by the respective ASME Code, Section II, material specification for the particular type or grade of alloy in accordance with Regulatory Position C.2.

The Westinghouse position concerning material inspection programs and Regulatory Position C.3 is discussed in Section 5.2.3.4.

Westinghouse meets the intent of Regulatory Position C.4 in the manner discussed in detail in Section 5.2.3.4. However, the guide's exception (a) to Regulatory Position C.4 established 200°F as the upper limit for dissolved oxygen concentration above 0.1 parts per million (ppm). This temperature limit should be increased to 250°F which provides for much quicker reduction of the oxygen concentration by reaction with hydrazine. Startup operations provide for adding hydrazine after the temperature is at about 225°F. Oxygen scavenging at this temperature is rapid and complete; below 200°F, considerable time can be encountered in the oxygen removal operations.

The Westinghouse position is that the significant chemistry control associated with the above limits on oxygen is the control of chloride and fluoride ion concentrations at less than 0.15 ppm each at all times. The guide's exception (b) to Regulatory Position C.4 is covered in the discussion of delta ferrite in Section 5.2.3.4.

Westinghouse complies with Regulatory Position C.5 in the manner discussed in Section 5.2.3.4. The guide's exception (a) to Regulatory Position C.5 is covered in Section 5.2.3.4 on delta ferrite.

Westinghouse complies with Regulatory Position C.6 in the manner discussed in Section 5.2.3.4.

Regulatory Guide 1.47

Bypassed and Inoperable Status Indication for Nuclear Power Plant Safety Systems

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.48

Design Limits and Loading Combinations for Seismic Category I Fluid System Components

Discussion

Westinghouse supplied components are designed using the stress limits and loading combinations presented in Sections 3.9N.1 and 5.2 for Code Class 1 components and in Section 3.9N.3 for Code Class 2 and 3 components. The conservatism in these limits and the associated ASME design requirements precludes any component structural failure.

The operability of active Code Class 1, 2 and 3 valves and active Code Class 2 and 3 pumps (there are no active Class 1 pumps) will be verified by methods detailed in Sections 3.9N.1 and 5.2 for Code Class 1 components and in Section 3.9N.3 for Code Class 2 and 3 components.

The use of the above stated methods provides an acceptable alternate method to meeting the guidance of this regulatory guide dated May 1973.

Also refer to Appendix 1A(B).

Regulatory Guide 1.49

Power Levels of Nuclear Power Plants

Discussion

The CPNPP meets the recommendations of Revision 1 (12/73) of Regulatory Guide 1.49 since the projected initial power level is less than 3800 megawatts thermal (MWt) and analyses and evaluation are made at assumed core power levels less than the levels in this regulatory guide.

Regulatory Guide 1.50

Control of Preheat Temperature for Welding of Low-Alloy Steel

Discussion

Westinghouse considers that this regulatory guide (dated May 1973) applies to ASME Code, Section III, Class 1 components.

The Westinghouse practice for Class 1 components is in agreement with the recommendations of Regulatory Guide 1.50 except for Regulatory Positions C.1.b and C.1.c. For Class 2 and 3 components, Westinghouse does not apply any of Regulatory Guide 1.50 recommendations.

In the case of Regulatory Position C.1.b, the welding procedures are qualified within the preheat temperature ranges required by Section IX of the ASME Code. Westinghouse experience has shown excellent quality of welds using the ASME qualification procedures.

In the case of Regulatory Position C.2, the Westinghouse position is that this guide recommendation is both unnecessary and impractical. Code acceptance low-alloy steel welds have been and are being made under present Westinghouse specified procedures. It is not necessary to maintain the preheat temperature until a post-weld treatment has been performed as recommended by this regulatory guide, in the case of large components. In the case of reactor vessel main structural welds, the practice of maintaining preheat until the intermediate or final post-weld heat treatment has been followed by Westinghouse. In either case, the welds have shown high integrity. Westinghouse practices are documented in Reference [8], which has been accepted by the NRC.

Regulatory Guide 1.53

Application of the Single-Failure Criterion to Nuclear Power Plant Protection Systems

Discussion

Westinghouse furnished systems meet the recommendations of this regulatory guide (dated June 1973) in accordance with the comments of Section 7.1.2.7.

Also refer to Appendix 1A(B).

Regulatory Guide 1.54

Quality Assurance Requirements for Protective Coatings Applied to Water-Cooled Nuclear Power Plants

Discussion

For the CPNPP, Westinghouse employs process specifications and the Westinghouse Quality Assurance Program, including quality assurance surveillance and auditing, to provide adequate confidence that coating work within Westinghouse scope will perform satisfactorily in service.

This regulatory guide (dated June 1973) recognizes ANSI N101.4-1972. Westinghouse uses alternate methods which have employed process specifications for protective coatings for several years. The Westinghouse process specifications cover the application of paint systems to structures and components in the reactor Containment which may come in contact with the fission product removal and/or Containment cooling spray. Regulatory Guide 1.54 provides that equipment covered with fabricated metal insulation does not require protective coatings, and thus, may not require the use of this Westinghouse process specification, e.g., steam generators. Applicable coating requirements are included in procurement orders.

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.58

Qualification of Nuclear Power Plant Inspection, Examination, and Testing Personnel

Discussion

For work within Westinghouse scope performed for the CPNPP, before January 1, 1975, the qualification of inspection, examination, and testing personnel was controlled by standard industry practice with the exception of nondestructive examination personnel, who were qualified in accordance with the requirements of SNT-TC-1A. The qualification of inspection, examination, and testing personnel was accomplished locally by Westinghouse suppliers through on-the-job training.

For activities initiated on the CPNPP after January 1, 1975, Westinghouse follows the guidance of this regulatory guide (dated August 1973) as defined in Reference [5] and as described below.

This guide recognizes ANSI N45.2.6-1973. Westinghouse policies and procedures for qualification of personnel engaged in inspection, examination and testing activities follow the guidance of this standard. Westinghouse uses demonstrated capability of performing the assigned tasks to predetermine standards or levels of proficiency as the primary basis for evaluating and certifying the personnel as an acceptable alternative to the specific years of education/experience.

Westinghouse applies the guidance of this standard to personnel who perform inspection, examination and testing activities including surveillance of these activities for safety-related equipment, materials and services in the Nuclear Energy Systems Division and at outside suppliers.

Regulatory Guide 1.59

Design Basis Floods for Nuclear Power Plants

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.60

Design Response Spectra for Seismic Design of Nuclear Power Plants

Discussion

The design response spectra of Revision 1 (12/73) of Regulatory Guide 1.60 are acceptable to Westinghouse as long as the damping values discussed below under Regulatory Guide 1.61 are acceptable.

Also refer to Appendix 1A(B).

Regulatory Guide 1.61

Damping Values for Seismic Design of Nuclear Power Plants

Discussion

The damping values listed in Regulatory Guide 1.61 (dated October 1973) are acceptable to Westinghouse with the single exception of the large piping systems faulted condition value of 3 percent critical. Higher damping values when justified by documented test data have been provided for in Regulatory Position C.2. A conservative value of 4 percent critical has therefore been justified by testing for the Westinghouse reactor coolant loop configuration in Reference [9] and has been approved by the NRC Staff.

For piping systems analyzed by the response spectrum method, ASME Code Case N-411 damping values may be used in lieu of the damping values in this Regulatory Guide.

Also refer to Appendix 1A(B).

Regulatory Guide 1.62

Manual Initiation of Protective Actions

Discussion

Westinghouse furnished systems meet the recommendations of this regulatory guide (dated October 1973) in accordance with the comments of Section 7.3.2.2.7.

Regulatory Guide 1.63

Electric Penetration Assemblies in Containment Structures for Light- Water-Cooled Nuclear Power Plants

Discussion

The Reg. guide as well as IEEE Std. 317 are not applicable to the NSSS Scope of Supply.

Regulatory Guide 1.64

Quality Assurance Requirements for the Design of Nuclear Power Plants

Discussion

The Westinghouse commitment, as described in Chapter 17 of the CPNPP Preliminary Safety Analysis Report, was designed to meet the requirements of 10CFR50, Appendix B, which is an acceptable method for following the guidance of ANSI N45.2. For activity initiated by Westinghouse after January 1, 1975 for the CPNPP, the control measures described in Reference [5] are applicable. Reference [5] commits Westinghouse to meet the requirements of 10CFR50, Appendix B and follow the guidance of the NRC. Specifically, Westinghouse follows the guidance of ANSI/ASME NQA-1 for Unit 1 and ANSI N45.2.11-1974 for Unit 2, which is recognized by this standard in the design work for safety-related NSSS equipment. Westinghouse utilizes different but equivalent forms than those shown as samples in the standard. In regard to design verification, it is performed by individuals or groups other than those who performed the original design. However, in exceptional cases, when the designer's supervisor maintains a detailed expertise on the design, the supervisor will perform the design verification function, and document the reason for this action.

Also refer to Appendix 1A(B).

Regulatory Guide 1.65

Materials and Inspections for Reactor Vessel Closure Studs

Discussion

Westinghouse is in agreement with Regulatory Guide 1.65 (dated 10/73) except for material and tensile strength guidelines.

Westinghouse has specified both 45 ft-lb and 25 mils lateral expansion for control of fracture toughness determined by Charpy-V testing, required by the ASME Code, Section III, Summer 1973 Addenda and 10CFR50, Appendix G (July 17, 1973, Paragraph IV.A.4). These toughness requirements assure optimization of the stud bolt material tempering operation with the accompanying reduction of the tensile strength level when compared with previous ASME Code requirements.

The specification of both impact and maximum tensile strength as stated in the guide results in unnecessary hardship in procurement of material without any additional improvement in quality.

The closure stud bolting material is procured to a minimum yield strength of 130,000 psi and a minimum tensile strength of 145,000 psi. This strength level is compatible with the fracture toughness requirements of 10CFR50, Appendix G (July 17, 1973, Paragraph I.C), although higher strength level bolting materials are permitted by the code. Stress corrosion has not been observed in reactor vessel closure stud bolting manufactured from material of this strength level. Accelerated stress corrosion test data do exist for materials of 170,000 psi minimum yield strength exposed to marine water environments stressed to 75 percent of the yield strength (given in Reference 2 of the guide). These data are not considered applicable to Westinghouse reactor vessel closure stud bolting because of the specified yield strength differences and a less severe environment; this has been demonstrated by years of satisfactory service experience.

The ASME Code requirement for toughness for reactor vessel bolting has precluded the guide's additional recommendation for tensile strength limitation, since to obtain the required toughness levels, the tensile strength levels are reduced. Prior to 1972, the ASME Code required a 35 ft-lb toughness level which provided maximum tensile strength levels ranging from approximately 155 to 178 kpsi (Westinghouse review of limited data - 25 heats). After publication of the Summer 1973 Addenda to the ASME Code and 10CFR50, Appendix G, wherein the toughness requirements were modified to 45 ft-lb with 25 mils lateral expansion, all bolt material data reviewed on Westinghouse plants showed tensile strengths of less than 170 kpsi.

Additional protection against the possibility of incurring corrosion effects is assured by:

a. Decrease in level of tensile strength comparable with the requirement of fracture toughness as described above.

b. Design of the reactor vessel studs, nuts, and washers, allowing them to be completely removed during each refueling permitting visual and/or nondestructive inspection in parallel with refueling operations to assess protection against corrosion, as part of the inservice inspection program.

c. Design of the reactor vessel studs, nuts, and washers, providing protection against corrosion by allowing them to be completely removed during each refueling and placed in storage racks on the Containment operating deck, as required by Westinghouse refueling procedures. The stud holes in the reactor flange are sealed

with special plugs before removing the reactor closure. Thus, the bolting materials and stud holes are never exposed to the borated refueling cavity water.

Regulatory Guide 1.66

Nondestructive Examination of Tubular Products

Discussion

The guide (dated October 1973) states that "Nondestructive examination applied to tubular products used for components of the reactor coolant pressure boundary and other safety-related systems...should be capable of detecting unacceptable defects regardless of defect shape, orientation, or location in the product." To accomplish this, the regulatory guide suggests the addition of angle beam scanning in two axial directions.

Westinghouse considers the regulatory position regarding angle beam scanning in the axial direction as technically unnecessary since any flaws which might be developed by the processes employed in tubular product manufacture are invariably oriented in the axial direction, and the probability of developing metallurgical flaws of other than axial orientation is virtually nil. Flaws of transverse or circumferential orientation which might be developed would normally be mechanically induced surface defects which should be detected by surface nondestructive examination procedures.

The primary pressure boundary and safety-related tubular products within the Westinghouse scope of supply and the nondestructive examinations applied are tabulated in Table 1A(N)-1. In all cases the volumetric nondestructive examination is designed to detect the flaws inherent to the manufacturing process or processes employed. In those few cases where compliance with the guide is not indicated, Westinghouse believes that the nondestructive examinations performed in the normal procurement of the tubular products covered by the guide achieve the same purpose as the guide.

The hardwater items identified in Table 1A(N)-1 as not being in compliance with Regulatory Guide 1.66 are constructed in accordance with the applicable ASME Code, Section III rules as a minimum.

However, the ASME Code, Section III rules do not require the suggested provisions of the regulatory guide for tubular products which do not fall within the size range of 2.5 to 6 inches, outside diameter.

Tubular products for core support structures function only as structural beams. For the CPNPP these tubular products were procured prior to the effectivity of Section NG of the ASME Code but were purchased using the guidelines of draft Section NG-2000.

Regulatory Guide 1.71

Welder Qualification for Areas of Limited Accessibility

Discussion

Westinghouse practice does not require qualification or requalification of welders for areas of limited accessibility as described by the guide (dated December 1973) and has provided welds of high quality.

Westinghouse believes that limited accessibility qualification or requalification, which are additional to ASME Code, Section III and IX requirements, is an unduly restrictive requirement for shop fabrication, where the welders' physical position relative to the welds is controlled and does not present any significant problems. In addition, shop welds of limited accessibility are repetitive due to multiple production of similar components, and such welding is closely supervised.

For field application, the type of qualification should be considered on a case-by-case basis due to the great variety of circumstances encountered.

Regulatory Guide 1.84

Code Case Acceptability - ASME Section III Design and Fabrication

Discussion

Refer to the discussion of Regulatory Guide 1.85 and Appendix 1A(B).

Regulatory Guide 1.85

Code Case Acceptability - ASME Section III Materials

Discussion

The CPNPP had its second-round Preliminary Safety Analysis Report questions issued after the July 1, 1974 date on which the original versions of Regulatory Guides 1.84 and 1.85 were made effective. The major NSSS components that are Code Class 1, 2 or 3 were ordered before Westinghouse instituted procedures to control the use of code cases. The only examples of code

cases known to have been used that are not authorized by way of Regulatory Guides 1.84 and 1.85 are Code Case 1528 and Code Case 1637. Westinghouse is conducting a testing program to determine fracture toughness properties of the materials allowed by Code Case 1528 and is in the process of obtaining authorization. Authorization has been obtained from the Commission for use of Code Case 1637 in the purchase of tubing for Class 2 and 3 components.

Refer to Appendix 1A(B) for a further discussion of the CPNPP position.

Termination of Operating Licenses for Nuclear Reactors

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.87

Guidance for Construction of Class 1 Components in Elevated- Temperature Reactors (Supplement to ASME Section III Code Cases 1592, 1593, 1594, 1595, and 1596)

Discussion

This regulatory guide is not applicable to the CPNPP.

Regulatory Guide 1.88

Collection, Storage, and Maintenance of Nuclear Power Plant Quality Assurance Records

Discussion

This regulatory guide recognizes N45.2.9-1974. For the CPNPP, the Westinghouse Quality Assurance Records Program follows the guidance of this standard. Records are identified, indexed, stored, and protected in a manner consistent with Revision 2 (10/76) of Regulatory Guide 1.88.

For active files, Westinghouse maintains duplicate records in separate geographical locations as an alternative to the protective construction provisions of the standard.

Also refer to Appendix 1A(B) and 17.2.17.

Regulatory Guide 1.89

Qualification of Class 1E Equipment for Nuclear Power Plants

Discussion

The Westinghouse approach to satisfying the guidelines of Regulatory Guide 1.89 (dated November 1974) and IEEE Standard 323-1974 is documented in WCAP 8587, Revision 6-A which has been reviewed and approved by the NRC. However, as supported by the statements

of consideration for 10CFR50.49 (Federal Register, 48FR2731, January 21, 1983), the recommendations of this regulatory guide need not be applied for Class 1E equipment located in a mild environment area.

Regulatory Guide 1.90

Inservice Inspection of Prestressed Concrete Containment Structures with Grouted Tendons

Discussion

This regulatory guide is not applicable to the CPNPP.

Regulatory Guide 1.91

Evaluation of Explosions Postulated to Occur on Transportation Routes Near Nuclear Power Plant Sites

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.92

Combining Modal Responses and Spatial Components in Seismic Response Analysis

Discussion

Westinghouse takes exception to several major positions in this regulatory guide (dated December 1974) as discussed below.

1. Combination of closely spaced modes

   In Section B.1 it is stated that, “Because of the likelihood that the response of closely spaced modes add directly, the values of the response of these modes should be combined by taking the absolute sum of the maximum values of the response of individual closely spaced modes, as explained in Regulatory Position C.2 of this guide.”

   The regulatory guide cited as its only reference in the closely spaced modes discussion one which did not propose to take the absolute sum of maximum values of the response of individual closely spaced modes. Instead, it has recommended that closely spaced modes be added using a coefficient E which is less than or equal to 1.0 and is a function of the frequency ratio, duration of the earthquake, and damping values. Similar formulas have been proposed by the ASME Dynamic Analysis Task Force which utilize the same E coefficient.

   The formula proposed in Regulatory Guide 1.92 has not been thoroughly discussed in the literature and does not realistically represent the dependence of the response of closely spaced modes on the proximity of frequencies and the modal damping values.

Westinghouse has presented an alternative approach in Section 3.7(N) which has factored in the E coefficient. This formula is more conservative than the referenced formula, since E is considered to be positive for all closely spaced modes, but is equal to or less conservative than the formula proposed in the regulatory guide.

2. Time-history dynamic analysis

Regulatory Position C.3 recommends that time-history dynamic analysis be conducted independently for each of the three directions and summed by the square root of the sum of the squares approach.

The three orthogonal earthquake components are statistically independent, and more importantly, they occur simultaneously. Furthermore, time-history analysis is most often conducted in order to properly account for either geometrical or material nonlinearities. All systems do not behave linearly in responding to the loading. Consequently, all three components of the input may need to be applied simultaneously, and therefore, simultaneous use of these components should be allowed by the regulatory guide in the time-history analysis.

For some systems, independent application of each time-history is justified and the methods given in the regulatory guide are applicable. Simultaneous application, however, must be included as an option.

For response spectra analyses, the option should be provided in the regulatory guide for the simultaneous application of the three load components of the earthquake rather than that method specified in the regulatory guide. Currently, the guide recommends independent application of the three components of the earthquake with subsequent combination by the square root of the sum of the squares. Westinghouse is currently preparing computer programs for the analyses of the Reactor Coolant System which will apply the three seismic load components simultaneously. In the seismic analysis, this method gives generally equivalent conservatisms in comparisons to the independent application of the loads and should be permitted by the regulatory guide.

Discussion

CPNPP complies with Revision 2 (5/88) of this Regulatory Guide as discussed in Section 5.3.2.1.

Regulatory Guide 1.100

Seismic Qualification of Electric Equipment for Nuclear Power Plants

Discussion

As discussed in Section 3.10N, the CPNPP NSSS program for seismic qualification of safety-related electrical equipment to the recommendations of Regulatory Guide 1.100 is delineated in References 16 and 17. In summary, seismic qualification will be demonstrated by the following methods:

1. For equipment not subject to high energy line break conditions, which has been previously qualified by the single axis sine beat method (after demonstration of no resonant frequency below 33 hertz) as permitted by IEEE Standard 344-1971 "IEEE Guide for Seismic Qualification of Class 1 Electric Equipment for Nuclear Power Generating Stations" and included in the NRC seismic audit and, where required by the staff, the Supplemental Qualification Program, no additional qualification testing is required to demonstrate acceptability to IEEE 344-1975 provided that:

    a. It can be shown, by separate component testing and/or analysis, that there are no aging mechanisms that could prejudice the previously completed seismic qualification.

    b. Any design modifications made to the equipment do not significantly affect the seismic characteristics of the equipment.

    c. The adequacy of the original seismic test levels can be demonstrated as conservative by plant specific verification.

2. For new equipment, or equipment that cannot meet the provisions of item 1 above, seismic qualification will be performed in accordance with IEEE Standard 344-1975, "IEEE Recommended Practices for Seismic Qualification of Class 1E Equipment for Nuclear Power Generating Stations." The method to be employed (i.e., test and/or analysis) is indicated, for the safety-related equipment in the Westinghouse scope of supply, in Reference 17. Where multifrequency biaxial inputs are employed for testing, the methodology described in Reference 18 will be employed. When flexible equipment size and weight precludes biaxial testing (e.g., enclosures), single axis testing with justification will be utilized to meet IEEE Standard 344-1975. For rigid equipment (i.e., no resonant frequency below 33 hertz), qualification will be by analysis in accordance with IEEE Standard 344-1975.

All Class 1E equipment located in a mild environment area will be seismically qualified as described above and in FSAR Sections 3.10N and 3.10B, except that the additional requirements imposed by IEEE Standard 323- 1974 do not apply. The procurement documents will specify that the effects of aging on seismic qualification be assessed and if there are aging effects, require pre-aging or analysis of aging effects as part of the seismic qualification.

Refer to FSAR Section 3.10N for further discussion of Regulatory Guide 1.100.

Regulatory Guide 1.105

Instrument Setpoints

Discussion

CPNPP complies with the intent of Revision 2 (2/86) of this guide as discussed below.

Westinghouse Standard Technical Specifications provide the margin from the nominal trip setpoint to the allowable value to account for rack drift and calibration when measured during periodic testing. The allowances between the nominal trip setpoint technical specification limit and the safety analysis limit include a statistical combination of the following items:

1. the inaccuracies of the instrumentation,

2. non-instrument related effects, i.e., process measurement accuracy,

3. uncertainties in the calibration of both the transmitter and racks, and

4. Adverse environmental effects on transmitter accuracy caused by postulated or limiting postulated events (only for those systems required to mitigate consequences of an accident).

Potential transient overshoot is accounted for in the modeling of the event in the safety analyses.

Westinghouse chooses setpoints such that the accuracy of the instrumentation is sufficient to meet the assumptions of the safety analyses.

The range of the instrumentation is chosen based on the span necessary for the function. Narrow range instrumentation will be used where necessary. Instrumentation will be selected based on expected environmental and accident conditions. The need for qualification testing is evaluated and justified on a case-by-case basis.

Administrative procedures, coupled with the present cabinet alarms and/or locks, provide sufficient control over the setpoint adjustment mechanism such that no integral setpoint securing device is required. Integral setpoint locking devices are not supplied.

This regulatory guide was withdrawn June 23, 1977.

Regulatory Guide 1.120

Fire Protection Guidelines for Nuclear Power Plants

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.121

Bases for Plugging Degraded PWR Steam Generator Tubes

Discussion

The plugging criteria for the steam generator U-tubes, as specified in the plant Technical Specifications, is based on the more conservative limit required by paragraph IWB-3521.1, Section XI of the ASME Boiler and Pressure Vessel Code, than the plugging criteria derived from the Regulatory Guide 1.121 (dated August, 1976) analysis. Alternate repair criteria which may exceed the plugging limit specified by IWB-3521.1 are defined in the plant Technical Specifications.

Regulatory Guide 1.122

Development of Floor Design Response Spectra for Seismic Design of Floor-Supported Equipment or Components

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.123

Quality Assurance Requirements for Control of Procurement of Items and Services for Nuclear Power Plants

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.124

Design Limits and Loading Combinations for Class 1 Linear-Type Component Supports

Discussion

The CPNPP NSSS position on Revision 1 (1/78) of this guide is as follows:

1. Paragraph B.1

   In the regulatory guide, an increase in bolt allowable stress under emergency and faulted conditions is not permitted. Westinghouse believes that the present ASME Code rules are adequate for bolted connections.

   It is recognized after extensive experimental work by several researchers that the interaction curve between the shear and tension stress in bolts is more closely represented by an ellipse and not a line. This has been clearly recognized by the ASME. Code Case 1644-6 specifies stress limits for bolts and represents this tension/shear relationship as a non-linear interaction equation (incorporated into ASME III Appendix XVII via the Winter 77 Addenda) and has a built-in safety factor that ranges between 2 and 3 (depending on whether the bolt load is predominantly tension or shear) based on the actual strength of the bolt as determined by test. [19]

Study of three interaction curves of allowable tension and shear stress based on the ASME Code (emergency condition allowables per XVII-2110 and faulted condition allowables per F-1370) and the ultimate tensile and shear strength of bolts indicates that there is adequate safety margin between the emergency and faulted condition allowables and failure of the bolts. [20]

From this study it is observed that:

a. For the emergency condition, the safety factor (ratio of ultimate strength to allowable stress) varies between a minimum of 1.63 and a maximum of 2.73 depending upon the actual tensile stress/shear (T/S) ratio on the bolt.

b. For the faulted condition, the safety factor varies between a minimum of 1.36 to a maximum of 2.29, again depending upon actual T/S ratio on the bolt.

The stress limits used for Class 1 component bolting material are those given in ASME III Appendix F-1323.1(b), $Pm \leq 2.4\ Sm$ or $0.7\ S_u$ (whichever is less) using the material properties of Table I-1.3 taken at the appropriate temperature.

It is thus reasonable to allow an increase in these limits for the emergency and faulted conditions.

Based on the above discussion, for the emergency and faulted conditions, Westinghouse will use allowable bolt stresses specified in Code Case 1644-6, as increased according to the provisions of XVII-2100(a) and F-1370(a), respectively.

The increased design limit for the stress range identified in NF-3231.1(a) shall be limited to the smaller of $2\ S_y$ or S_u unless otherwise justified by shakedown analysis.

2. Paragraphs B.5 and C.8

The reduction of allowable stresses to no greater than level B limits (which in reality are design limits since design, level A and level B limits are the same for linear supports) for support structures in those systems with safety related functions occurring during emergency or faulted plant conditions is overly conservative. The primary concern is that the system remains capable of performing its safety function. For active components, this is accomplished through the operability program as discussed in Section 3.9N. In the case of Class 1 piping, maintaining the pipe stresses within level D limits assures that piping geometry is maintained and that required flow is not impeded. The selection of more restrictive stress limits for component supports is not necessary to assure the functional capability of the system.

3. Paragraph C.4

In the design of component support, member compressive axial loads shall be limited to 0.67 times the critical buckling strength. If, as a result of more detailed evaluation of the supports the member compressive axial loads can be shown to safely exceed 0.67 times the critical buckling strength for the faulted condition, verification of the support functional adequacy will be documented and submitted to the NRC for review. The member

compressive axial loads will not exceed 0.67 times the critical buckling strength without NRC acceptance. In no case shall the compressive load exceed 0.9 times the critical buckling strength.

This regulatory guide states that increases in Level A or B service limits does not apply to limits for bolted connections. The Westinghouse design of component supports restricts the use of bolting material to the following applications:

a. Westinghouse design uses bolting predominantly in tension. Oversized holes are generally provided and a mechanism other than the bolts is provided to take any shear loads. Shear or shear & tension interaction occur only in isolated locations;

b. Westinghouse bolts are limited to the following material A490, SA-354, SA-325, SA-540.

c. The diameters used range between 1/2" and 3".

These limitations on bolt usage are standard in the Westinghouse supports. We will limit tensile loads in the bolts to 0.7 S_u, but not to exceed in any case 0.9 S_y. The allowables are taken at temperature. In those few cases where bolts are used in shear or tension and shear, ASME Code Appendix XVII - 2460 Requirements will apply with an increase factor that is defined in Regulatory Guide 1.124 or in Appendix F-1370. This provides an adequate margin of safety for the Westinghouse design. If future revisions to the bolting criteria in ASME Section III modify the Westinghouse criteria listed above, we will review the criteria at the time.

4. Paragraph C.6(a)

Westinghouse will interpret this paragraph as follows: "The stress limits of XVII-2000 of Section III and Regulatory Position 3 increased according to the provisions of XVII-2110(a) of Section III and Regulatory Position 4, should not be exceeded for component supports designed by the linear elastic analysis method."

5. Paragraph C.7(b)

Westinghouse will use the provisions of F-1370(d) to determine service level D allowable loads for supports designed by the lead rating method. If future revisions to Appendix F modify this criteria, it will be reviewed further. If the load rating method is used, further details of its implementation will be provided at that time.

Also refer to Appendix 1A(B).

Regulatory Guide 1.125

Physical Models for Design and Operation of Hydraulic Structures and Systems for Nuclear Power Plants

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.126

An Acceptable Model and Related Statistical Methods for the Analysis of Fuel Densification

Discussion

Fuel for CPNPP is provided by Westinghouse. The methodology for the analysis of fuel densification used by Westinghouse is described in Reference 12.

Regulatory Guide 1.127

Inspection of Water-Control Structures Associated with Nuclear Power Plants

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.128

Installation Design and Installation of Large Lead Storage Batteries for Nuclear Power Plants

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.129

Maintenance, Testing, and Replacement of Large Lead Storage Batteries for Nuclear Power Plants

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.130

Service Limits and Loading Combinations for Class 1 Plate- and Shell-Type Component Supports (Revision 1, October, 1978)

Discussion

The Applicant takes the following exceptions to this Regulatory Guide:

1. Regulatory Guide states in Paragraph B.1:

   "Allowable design limits for bolted connections are derived on a different basis that varies with the size of the bolt. For this reason, the increases permitted by NF-3224 and F-1323.1(a) of Section III are not directly applicable to bolts and bolted connections."

   It is the Applicant's position that it is reasonable to allow an increase in the limits for bolted connections for emergency and faulted conditions. Further justification of this position can be found in the discussion of Regulatory Guide 1.124 on Class 1 linear type supports.

2. Paragraphs C.2, C.4(a), and C.6(a) of the Regulatory Guide state that the allowable buckling strength should be calculated using a design margin of 2 for flat plates and 3 for shells for normal, upset and emergency conditions.

   In the design of plate-type supports, member compressive axial loads shall be limited per the requirements of Paragraph C.3 for normal, upset and emergency conditions.

3. In Paragraph C.7 of the Regulatory Guide, inclusion of the upset plant condition is unappropriate in the load combination under discussion. The Applicant will not include the upset plant condition in this combination.

4. In Paragraphs C.7(a) and B.1 of the Regulatory Guide, the stress limits of F-1370(c) are discussed. The criterion stated in F-1370(c), "...loads should be exceed 0.67 times the critical buckling strength of the support...".

   In the design of plate-type component supports, member compressive axial loads shall be limited to 0.67 times the critical buckling strength. If, as a result of a more detailed evaluation of the supports the member compressive axial loads can be shown to safely exceed 0.67 times the critical buckling for the faulted condition, verification of the support function adequacy will be documented and submitted to the NRC for review. The member compressive axial loads will not exceed 0.67 times the critical buckling strength without NRC acceptance.

5. In Paragraph C.7(b) of the Regulatory Guide, the limit based on the test load given in the Regulatory Guide, T.L. x 0.7 $S'_u/_{Su}$, is overly conservative and is inconsistent with ASME Code requirements presented in Appendix F.

   The Applicant will use the provisions of F-1370(c) to determine service level D allowable loads for supports designed by the load rating method.

Regulatory Guide 1.131

Qualification Tests of Electric Cables, Field Splices, and Connections for Light-Water-Cooled Nuclear Power Plants

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.132

Site Investigations for Foundations of Nuclear Power Plants

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.133

Loose-Part Detection Program for the Primary System of Light-Water- Cooled Reactors

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.134

Medical Evaluation of Nuclear Power Plant Personnel Requiring Operator Licenses

Discussion

Regulatory Guide 1.135

Normal Water Level and Discharge at Nuclear Power Plants

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.136

Material for Concrete Containments

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.137

Fuel-Oil Systems for Standby Diesel Generators

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.138

Laboratory Investigations of Soils for Engineering Analysis and Design of Nuclear Power Plants

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.139

Guidance for Residual Heat Removal

Discussion

In lieu of Regulatory Guide 1.139, CPNPP addressed Branch Technical Position RSB 5-1 as provided in FSAR Chapter 5.

Regulatory Guide 1.140

Design, Testing, and Maintenance Criteria for Normal Ventilation Exhaust System Air Filtration and Adsorption Units of Light-Water- Cooled Nuclear Power Plants

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.141

Containment Isolation Provisions for Fluid Systems

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.142

Safety-Related Concrete Structures for Nuclear Power Plants (Other Than Reactor Vessels and Containments)

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.143

Design Guidance for Radioactive Waste Management Systems, Structures, and Components Installed in Light-Water-Cooled Nuclear Power Plants

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.144

Auditing of Quality Assurance Programs for Nuclear Power Plants

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.145

Atmospheric Dispersion Models for Potential Accident Consequence Assessments at Nuclear Power Plants

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.146

Qualification of Quality Assurance Program Audit Personnel for Nuclear Power Plants

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.148

Functional Specification for Active Valve Assemblies in Systems Important to Safety in Nuclear Power Plants

Discussion

Refer to Appendix 1A(B).

Regulatory Guide 1.150

Ultrasonic Testing of Reactor Vessel Welds During Preservice and Inservice Examinations

Discussion

The CPNPP position on Revision 1 (2/83) of this guide is as follows:

Preservice Inspection

A partial R.G. 1.150 inspection was performed on Units 1 and 2 reactor vessels in accordance with Reference [21].

Inservice Inspection

CPNPP complies with revision 1 of this regulatory guide.

Regulatory Guide 1.155

Station Blackout

Discussion

Refer to Appendix 1A(B)

d) Unit 2 only.

e) These items are outside the range of O.D. sizes covered by those sections of the ASME Code, Section III, which incorporate the ultrasonic testing provisions of the guide.

APPENDIX 1A(B) - DISCUSSION OF REGULATORY GUIDES

This appendix discusses the Comanche Peak Nuclear Power Plant (CPNPP) positions on, and compliance with, Division 1 regulatory guides as they apply to the balance of plant design and construction as well as start-up and operations. Appendix 1A(N) is provided separately for the NSSS related information.

Identification of specific issues of regulatory guides are provided in the discussions where appropriate.

Regulatory Guide 1.1

Net Positive Suction Head for Emergency Core Cooling and Containment Heat Removal System Pumps

Discussion

The CPNPP Containment Spray System design complies with the requirements of Safety Guide 1 (11/2/70) except as follows:

In the calculation of the net positive suction head (NPSH) for containment spray pumps it is assumed that the containment pressure is equal to the vapor pressure of the sump water.

The above assumption is conservative and consistent with the intent of the regulatory guide.

Also refer to Appendix 1A(N) and Section 6.2.2.3.4 for further discussion.

Regulatory Guide 1.2

Thermal Shock to Reactor Pressure Vessels

Discussion

Refer to Appendix 1A(N).

Regulatory Guide 1.3

Assumptions Used for Evaluating the Potential Radiological Consequences of a Loss of Coolant Accident for Boiling Water Reactors

Discussion

This regulatory guide is not applicable to the CPNPP which has pressurized water reactor steam supply systems.

Regulatory Guide 1.4

Assumptions Used for Evaluating the Potential Radiological Consequences of a Loss of Coolant Accident for Pressurized Water Reactors.

Discussion

The analysis of the radiological consequences of the loss-of-coolant accident presented in Section 15.6.5 follows the guidance provided in Regulatory Guide 1.195 instead of Regulatory Guide 1.4.

Regulatory Guide 1.5

Assumptions Used for Evaluating Potential Radiological Consequences of a Steam Line Break Accident for Boiling Water Reactors.

Discussion

This regulatory guide is not applicable to the CPNPP which has pressurized water reactor steam supply systems.

Regulatory Guide 1.6

Independence Between Redundant Standby (Onsite) Power Sources and Between Their Distribution Systems

Discussion

The CPNPP design complies with the requirements of Safety Guide 6 (3/10/71). For details see Section 8.3.

Regulatory Guide 1.7

Control of Combustible Gas Concentrations in Containment Following a Loss of Coolant Accident

Discussion

Based on a revision to 10CFR50.44, Regulatory Guide 1.7 no longer applies to CPNPP. See Section 6.2.5.

Regulatory Guide 1.8

Personnel Selection and Training

Discussion

Minimum qualifications of unit staffs, with the exception of licensed Senior Reactor Operators and Reactor Operators, will be in accordance with Regulatory Guide 1.8, Revision 2. Minimum qualifications for licensed Senior Reactor Operators and Reactor Operators will be in accordance with Regulatory Guide 1.8, Revision 3.

The training requirements of Regulatory Guide 1.8, Revision 2 have been superseded by the provisions of 10CFR parts 50 and 55.

Regulatory Guide 1.9

Selection of diesel Generator Set Capacity for Standby Power Supplies

Discussion

The CPNPP Diesel generator sets comply with the requirements of Safety Guide 9 (3/10/71) with the following comment:

The voltage may dip below 75 percent of nominal voltage when the diesel generator breaker closes and energizes the two 2000/2666 kVA, 6.9 kV/480 V unit substation transformers supplied from each diesel generator. The dip is due to transformer magnetizing inrush current which exists for two to three cycles. The diesel generator sets are designed to recover to 80 percent of nominal voltage within 10 cycles for this transient. The effect on the first load groups (see Tables 8.3-1 and 8.3-2) therefore would be a maximum possible delay in motor starting of 12-13 cycles after closure of the diesel generator circuit breaker. However, the objective of the first load group and subsequent load groups is not affected. For details see Section 8.3.

Regulatory Guide 1.10

Mechanical (Cadweld) Splices in Reinforcing Bars of Category I Concrete Structures

Discussion

Testing and sampling of Mechanical (Cadweld) Splices in Reinforcing Bars of the CPNPP Concrete Containment Structure complies with the requirements of Revision 1 (1/2/73) of this regulatory guide. For other seismic Category I concrete structures, the testing and sampling of Mechanical (Cadweld) splices complies with the requirements of this guide except that the location of all splices are not recorded and shown in as-built drawings.

Also refer to Section 3.8.

Regulatory Guide 1.11

Instrument Lines Penetrating Primary Reactor Containment

Discussion

The CPNPP instrument lines penetrating primary reactor containment comply with the requirements of Safety Guide 11 (3/10/71), as described by Section 7.3.1.1.2 and 6.2.4.1.4.

Also refer to Appendix 1A(N).

Regulatory Guide 1.12

Instrumentation for Earthquakes

Discussion

The installation of instrumentation for earthquakes in the CPNPP plant meets the intent of Revision 1 (4/74) of this regulatory guide with respect to the ability to determine exceedance of the OBE in a timely manner. Seismic instrumentation includes only the free-field triaxial accelerometer installed in the Yard. Determination of OBE exceedance will be based on the methods of ANSI/ANS-2.10-2003, “Criteria for the Handling and Initial Evaluation of Records from Nuclear Power Plant Seismic Instrumentation.”

Also refer to Section 3.7B.4.

Regulatory Guide 1.13

Spent Fuel Storage Facility Design Basis

Discussion

The design of the CPNPP spent fuel storage facility complies with Revision 1 (12/75) of this regulatory guide except that the air filtration system is not actuated by a high radiation level alarm. Instead the normal plant exhaust filtration system operates continuously. Refer to Sections 3.5, 3.8.4, 9.1.2, 9.1.3, 9.1.4 and 9.4.2 for details.

Regulatory Guide 1.14

Reactor Coolant Pump Flywheel Integrity

Discussion

Refer to Appendix 1A(N).

Regulatory Guide 1.15

Testing of Reinforcing Bars for Category I Concrete Structures

Discussion

The testing of reinforcing bars for CPNPP Category I concrete structures complies with the requirements of Revision 1 (12/28/72) of this regulatory guide.

Also refer to Section 3.8.

Regulatory Guide 1.16

Reporting of Operating Information - Appendix A Technical Specifications

Discussion

This regulatory guide was withdrawn on August 11, 2009.

Regulatory Guide 1.17

Protection of Nuclear Power Plants Against Industrial Sabotage

Discussion

Regulatory Guide 1.17 endorses the requirements and recommendations of ANSI N18.17-1973. This criteria does not reflect current regulations or industry standards and has been superseded by more recent guidelines. CPNPP takes exception to Regulatory Guide 1.17 and ANSI N18.17-1973 and instead implements a security program in accordance with the current applicable regulations and guidelines identified in FSAR section 13.6.

Regulatory Guide 1.18

Structural Acceptance Test for Concrete Primary Reactor Containments (Revision 1, December 28, 1972)

Discussion

The structural acceptance test for the CPNPP Concrete Containments are in accordance with paragraph CC-6000 of the ASME B&PV Code, Section III, Division 2, 1980 Edition with Summer 1980 Addenda (as applicable to non-prototype containments). As such, this test is in conformance with Revision 1 of this regulatory guide except as follows:

Radial deflections of the containment walls are measured along four azimuths only.

Vertical deflections along one azimuth are measured at two equally spaced intermediate points between the dome apex and the springline and along four azimuths at the dome springline. Vertical deflection is also measured at the dome apex.

Only radial deflections at 12 points around the largest opening (the equipment hatch) are measured. In addition, the increase in diameter of the opening is measured in two mutually perpendicular directions.

See Subsection 3.8.1.7.1 for description of the test.

Regulatory Guide 1.19

Nondestructive Examination of Primary Containment Liner Welds

Discussion

The requirements for nondestructive examination of the CPNPP containment liner welds are in conformance with the intent of Revision 1 (08/11/72) of this regulatory guide by use of ASME-ACI 359 Code applicable to this type of structure and the alternate requirements as discussed in Sections 3.8.1 and 3.8.2. Acceptance criteria are those provided in Subsection 3.8.1.6.5.

Regulatory Guide 1.20

Comprehensive Vibration Assessment Program for Reactor Internals During Preoperational and Initial Startup Testing

Discussion

Refer to Appendix 1A(N).

Regulatory Guide 1.21

Measuring, Evaluating, and Reporting Radioactivity in Solid Wastes and Releases of Radioactive Materials in Liquid and Gaseous Effluents from Light-Water-Cooled Nuclear Power Plants

Discussion

Measuring, evaluating and reporting of radioactive materials released from CPNPP will meet the recommendations of Revision 1 (6/74) of this regulatory guide.

Also refer to Section 11.5.

Regulatory Guide 1.22

Periodic Testing of Protection System Actuation Functions

Discussion

Refer to Appendix 1A(N).

Regulatory Guide 1.23

Onsite Meteorological Programs

Discussion

The meteorological monitoring program at CPNPP complies with the requirements and those applicable recommendations of the Second Proposed Revision 1 to Regulatory Guide 1.23 (April, 1986) as discussed in Section 2.3. Refer to the CPNPP Offsite Dose Calculation Manual (ODCM), Section I, 4.3.3.6 and Bases 3/4.3.3.6 for an exception.

Refer to Section 2.3 for a description of the design and siting of the primary meteorological tower. The quality assurance program for meteorological monitoring is identified in FSAR Table 17A-1 and Section 17.2.

Regulatory Guide 1.24

Assumptions Used for Evaluating the Potential Radiological Consequences of a Pressurized Water Reactor Radioactive Gas Storage Tank Failure

Discussion

The analysis of the radiological consequences of the radioactive gas storage tank failure accident presented in Section 15.7.1 complies with the requirements of Safety Guide 24 (3/23/72) except that only gamma radiation contribution is taken into account in the determination of whole body exposures and the dose calculation methodology is consistent with Regulatory Guide 1.195.

Regulatory Guide 1.25

Assumptions used for Evaluating the Potential Radiological Consequences of a Fuel Handling Accident in the Fuel Handling and Storage Facility for Boiling and Pressurized Water Reactors

Discussion

The analysis of the radiological consequences of the fuel handling accident presented in Section 15.7.4 follows the guidance provided in Regulatory Guide 1.195 instead of that in Regulatory Guide 1.25.

Regulatory Guide 1.26

Quality Group Classifications and Standards for Water-, Steam-, and Radioactive-Waste-Containing Components of Nuclear Power Plants

Discussion

The CPNPP quality group classification described in Section 3.2.2 is generally in accordance with ANSI N18.2, Nuclear Safety Criteria for the Design of Stationary Pressurized Water Reactor Plants, 1973, which is an alternate acceptable method of meeting the intent of Revision 3 (2/76) of this regulatory guide. Deviations are described in Section 3.2.2.

Also refer to Appendix 1A(N).

Regulatory Guide 1.27

Ultimate Heat Sink for Nuclear Power Plants

Discussion

The CPNPP ultimate heat sink meets the requirements of Revision 2 (January 1976) of the Regulatory Guide 1.27 as described in Sections 2.3.1.2.10, 2.4.11.5, 2.4.11.6 and 9.2.5.

Regulatory Guide 1.28

Quality Assurance Program Requirements (Design and Construction)

Discussion

The quality assurance program (design and construction) for CPNPP complies with the requirements of Safety Guide 28 (6/7/72) except as stated in Appendix 1A(N). Revisions 1 (3/78) and 2 (2/79) of this guide are not addressed.

Also refer to Sections 17.1 and 17.2

Regulatory Guide 1.29

Seismic Design Classification

Discussion

The seismic Category I classifications of CPNPP structures, systems and components conforms to Revision 2 (2/76) of this regulatory guide.

Also refer to Appendix 1A(N) and Sections 3.1, 3.2 and 13.5.

Regulatory Guide 1.30

Quality Assurance Requirements for the Installation, Inspection, and Testing of Instrumentation and Electric Equipment

Discussion

Safety Guide 30 (8/11/72) is applicable to the installation, inspection, and testing of instrumentation and electric equipment at CPNPP. The quality assurance methods for operations phase activities will comply with the applicable guidance contained in this regulatory guide. The application of the requirements of ANSI N45.2.4 - 1972, as endorsed by this regulatory guide, will be in accordance with the guidance provided in ANSI N18.7 - 1976.

Also refer to ANSI/NCSL Z540-1-1994 “American National Standard for Calibration Laboratories and Measuring and Test Equipment General Requirements” for M&TE and reference standards traceability.

Also refer to Appendix 1A(N) and to Sections 17.1 and 17.2.

Regulatory Guide 1.31

Control of Ferrite Content in Stainless Steel Weld Metal

Discussion

The CPNPP design complies with the recommendations of Revision 3 (4/78) of this regulatory guide except as follows:

1. The acceptable alternative methods of FSAR Subsection 6.1B.1.1.3 are used.

2. The recommendations of Revision 1 (6/73) or Revision 2 (5/77) of this regulatory guide are used.

3. The exception described in Subsection 6.1B.1.1.4.

Also refer to Appendix 1A(N).

Regulatory Guide 1.32

Criteria for Safety-Related Electric Power Systems for Nuclear Power Plants

Discussion

The CPNPP design complies with the requirements of Revision 2 (2/77) of this regulatory guide. For details see Section 8.3.

Regulatory Guide 1.33

Quality Assurance Program (Operation)

Discussion

The quality assurance requirements for the operations phase of CPNPP are in compliance with Revision 2 (2/78) of this regulatory guide as implemented by ANSI N18.7-1976, "Administrative Controls and Quality Assurance for Operational Phase of Nuclear Power Plants", with the following exceptions:

1. Audit Intervals (Section 17.2.18)

Audits shall be performed at the intervals designated herein for each audit area. Schedules shall be based on the month in which the audit starts. For audits, other than those audit areas with maximum frequency specified by regulation (Security and Emergency Plan), an interval extension grace period of up to 25% may be used for the scheduled commencement date when conditions, such as plant operational considerations or to accommodate performance based observations of activities related to the audit area, make meeting the specified schedule date impractical. When an audit interval extension greater than one month is used, the next audit for that particular audit area will be scheduled from the original anniversary month rather than from the month of the extended audit.

2. Regulatory Position C.4

The quality assurance program has specified alternatives to the program area audit frequencies stated in Regulatory Position C.4. The quality assurance program schedules the audits provided for in Regulatory Position C.4 at 24 month frequencies. The audit schedule is performance-based and additional audits may be scheduled based upon program or functional area performance or other factors that indicate the need for increased assessment.

3. Biennial Reviews of Plant Procedures

The intent of the biennial review is accomplished by CPNPP programmatic controls already in place. The following controls assure that procedures are appropriately reviewed and revised to incorporate information based on plant operations, design changes, regulatory requirements, industry experience and other conditions that may impact plant procedures.

- Site Modification Process
- Corrective Action Program
- Off-Normal Occurrence
- User Feedback and Procedure Compliance
- Operating Experience Review
- Vendor Technical Information
- Licensed Document Change/50.59 Evaluation
- Commitment Tracking System (CTS)
- Trending Activities
- Infrequently Performed Evolutions Control
- Requalification Training
- Quality Assurance Activities

Note: 10CFR50.59 has been revised and the terminology in Section 4.3.4 of ANSI N18.7-1976 is no longer current. Section 17.2 has been updated to reflect the revision to 10CFR50.59.

4. Identification of QA Program Requirements in Procurement Documents

Quality Assurance program requirements consistent with 10CFR50 Appendix B or ANSI N45.2 are not imposed in procurement documents for commercial grade calibration services from a National Voluntary Laboratory Accreditation Program (NVLAP) or American Association for Laboratory Accreditation (A2LA) accredited calibration laboratory evaluated in accordance with Section 17.2.7.

Regulatory Guide 1.34

Control of Electroslag Weld Properties

Discussion

Refer to Appendix 1A(N).

Regulatory Guide 1.35

Inservice Inspection of Ungrouted Tendons in prestressed Concrete Containment Structures

Discussion

This regulatory guide is not applicable to the CPNPP which has a steel-lined, reinforced concrete containment structure.

Regulatory Guide 1.36

Nonmetallic Thermal Insulation for Austenitic Stainless Steel

Discussion

This regulatory guide is not applicable for components located inside CPNPP Containment Buildings, since only stainless steel metal reflective thermal insulation is used for austenitic stainless steel components located there. Nonmetallic thermal insulation used for austenitic stainless steel piping and components located outside the Containment Buildings meets the requirements of this regulatory guide dated February 23, 1973, with the exception of packaging and shipping requirements of paragraph C.1 of this guide. In lieu of controlled packaging and shipping, a receipt inspection is required, which consists of visual inspection for physical or water damage to shipping containers, to determine if insulation materials have been contaminated by external sources.

Also refer to Appendix 1A(N) and Section 6.1B, 6.2 and 5.2.3.

Regulatory Guide 1.37

Quality Assurance Requirements for Cleaning of Fluid Systems and Associated Components of Water-Cooled Nuclear Power Plants

Discussion

This regulatory guide is not applicable to the design and construction of CPNPP. The quality assurance methods for operating phase activities will comply with the applicable provisions of this regulatory guide, dated March 16, 1973, for those activities in this area which are similar to construction activities. The application of the requirements of ANSI N45.2.1 - 1973, as endorsed by this guide, will be in accordance with the guidance provided in ANSI 18.7 - 1976.

Also refer to Appendix 1A(N) and Section 17.2.

Regulatory Guide 1.38

Quality Assurance Requirements for Packaging, Shipping, Receiving, Storage, and Handling of Items for Water-Cooled Nuclear Power Plants

Discussion

This regulatory guide is not applicable to the design and construction of CPNPP. The quality assurance methods and administrative controls utilized in the area of packaging, shipping, receiving, storage and handling of items during the operations phase, as described in Section 17.2, will comply with the applicable guidance contained in Revision 1 (10/76) of this regulatory guide. The application of the provisions of ANSI N45.2.2 - 1972, as endorsed by this regulatory guide, will reflect the guidance provided in ANSI N18.7 - 1976.

Although ANSI N45.2.2 - 1972 is entitled, “Packaging, Shipping, Receiving, Storage, and Handling of Items for Nuclear Power Plants During the Construction Phase,” CPNPP meets the requirements of this standard during the operation phase with the clarification noted below:

Maintenance of items in-storage during operations will be in accordance with the preventive maintenance requirements of ANSI N18.7-1976 as supplemented by the EPRI guidelines for determining in-storage maintenance of items for nuclear facilities (NCIG-18).

For handling of items during operation phase, the following codes and standards shall apply.

ANSI B30.9 - 1971

ANSI B30.2 - 1976 (1967 for Design and Fabrication)

ANSI B30.5 - 1968

Regulatory Guide 1.38, Revision 2 (5/77) is not addressed.

Also refer to Appendix 1A(N) and Section 17.2.

Regulatory Guide 1.39

Housekeeping Requirements for Water-Cooled Nuclear Power Plants

Discussion

The administrative methods utilized to control station housekeeping practices will comply with ANSI N45.2.3 - 1973, as endorsed by Revision 2 (9/77) of this regulatory guide and as applied to the operations phase by the provisions of ANSI N18.7 - 1976.

Also refer to Section 17.2

Regulatory Guide 1.40

Qualification Tests of Continuous-Duty Motors Installed Inside the Containment of Water-Cooled Nuclear Power Plants

Discussion

This regulatory guide is not applicable to CPNPP since there are no continuous-duty Class 1E motors inside the Containment. For details see Section 3.11B.

Regulatory Guide 1.41

Preoperational Testing of Redundant On Site Electric Power Systems to Verify Proper Load Group Assignments

Discussion

The CPNPP onsite electric power system design complies with the preoperational testing requirements of this guide dated March 1973. For details see Section 8.3. The Initial Test Program, as described in Section 14.2, will comply with the provisions of this regulatory guide.

Regulatory Guide 1.42

Interim Licensing Policy on As Low As Practicable for Gaseous Radioiodine Release from Light-Water-Cooled Nuclear Power Reactors

Discussion

This regulatory guide was withdrawn March 22, 1976.

Regulatory Guide 1.43

Control of Stainless Steel Weld Cladding of Low Alloy Steel Components

Discussion

Refer to Appendix 1A(N).

Regulatory Guide 1.44

Control of the Use of Sensitized Stainless Steel

Discussion

The CPNPP design will comply with this regulatory guide, dated May 1973, except for Regulatory Position C6. The intergranular corrosion tests are eliminated because the weld arc heat input is controlled as described in Section 6.1B.1.1.2, Item 1e. Exception to this regulatory position is also taken for some equipment as described in Section 6.1B.11.2, Item 2.

Also refer to Appendix 1A(N) for further discussion.

Regulatory Guide 1.45

Reactor Coolant Pressure Boundary Leakage Detection Systems

Discussion

The reactor coolant pressure boundary leakage detection system meets the requirements of this guide, dated May 1973 with the exception of the radioactive gaseous monitor leak detection sensitivity (one gpm within one hour), as discussed in Section 5.2.5.3.

Regulatory Guide 1.46

Protection Against Pipe Whip Inside Containment

Discussion

In accordance with Standard Review Plan 3.6.2, protection against pipe whip inside the CPNPP Containment Buildings meets the requirements of Regulatory Guide 1.46, dated May 1973, or Branch Technical Position MEB 3-1 except as discussed in Section 3.6B.

Regulatory Guide 1.47

Bypassed and Inoperable Status Indication for Nuclear Power Plant Safety Systems

Discussion

The CPNPP bypassed and inoperable status indication system presented in Section 7.1 complies with the requirements of this regulatory guide dated May 1973.

Regulatory Guide 1.48

Design Limits and Loading Combinations for Seismic Category I Fluid System Components

Discussion

Balance of Plant components are designed using the stress limits and loading combinations presented in Section 3.9B.3. The conservatism in these limits and the associated ASME design requirements precludes any component structural failure.

The operability of active Code Class 2 and 3 valves and pumps will be verified by methods detailed in Section 3.9B.3.

Alternate provisions to meeting the guidance of this regulatory guide dated May 1973, have been utilized for valves and piping as provided in Section 3.9B.3.

Also refer to Appendix 1A(N).

Regulatory Guide 1.49

Power Levels of Nuclear Power Plants

Discussion

Refer to Appendix 1A(N).

Regulatory Guide 1.50

Control of Preheat Temperature for Welding of Low-Alloy Steel

Discussion

This guide, dated May 1973, is considered applicable to ASME Section III Code Class 1 components only.

The CPNPP design of Code Class 1 components is in agreement with the requirements of this regulatory guide except for Regulatory Positions 1(a) and 1(b). The recommendations of this regulatory guide are not applied to Code Class 2 and 3 components.

In the case of Regulatory Position 2, the low alloy steel welds have been made to ASME code requirements, and therefore the regulatory guide requirements are considered unnecessary.

Also refer to Appendix 1A(N) and 6.1B for further discussion.

Regulatory Guide 1.51

Inservice Inspection of ASME Code Class 2 and 3 Nuclear Power Plant Components

Discussion

This regulatory guide was withdrawn July 21, 1975.

Regulatory Guide 1.52

Design, Testing, and Maintenance Criteria for Post Accident Engineered-Safety-Feature Atmosphere Cleanup System Air Filtration and Adsorption Units of Light-Water-Cooled Nuclear Power Plants

Discussion

The CPNPP design meets the requirements of Revision 1(07/76) of Regulatory Guide 1.52, as indicated in Table 6.5-1, except part C.2.g instrumentation (see Section 6.5.1.5); part C.3.h, water drains; Part C.3.n, ductwork design; Part C.4.c, ease of maintenance; part C.4.d, test probes; Part C.5.b, Air flow distribution; Parts C.5.c, and C.5.d, in-place testing, and part C.6, laboratory testing criteria for activated carbon.

1. Part C.2.g, instrumentation:

   The flow rates and pressure drops for the ESF filtration units are not recorded or monitored from the control room. Operability of the ESF filtration units is maintained in accordance with the Technical Specifications. For those units provided for postulated DBA conditions, alarm annunciators in the Control Room are utilized to monitor design limits (e.g., flow, pressure drops, temperature, etc.) as well as system malfunction (e.g., damper, fan). This design conforms to the intent of NRC Regulatory Guide 1.52, Revision 1 (07/76).

2. Part C.3.e:

   In lieu of ORNL-NSIC-65, ANSI N509 was used for design.

3. Part C.3.f:

   In lieu of ORNL-NSIC-65 or ERDA 76-21, filter banks are arranged in accordance with ANSI/ASME N509-1980.

4. Part C.3.g:

   In lieu of ORNL-NSIC-65, ANSI N509 was used for design.

5. Part C.3.h, Water drains:

   Check valves have been used on some drains in lieu of seals or traps. The drains for the demister compartments of the four Primary Plant Ventilation System ESF filtration units have not been provided with seals, traps, or check valves. Any minimal airflow through the demister drain will be filtered prior to discharge at the stack. This design conforms to the intent of NRC Regulatory Guide 1.52, Revision 1 (07/76).

6. Part C.3.n, Ductwork Design:

   In lieu of ORNL-NSIC-65 OR ANSI/ASME N509-1976, ANSI/ASME N509-1980 is used as noted below.

   The following exception is taken to the ANSI/ASME N509-1980 standard (NRC R.G. 1.52, Rev. 2, refers to ANSI/ASME N509-1976):

   Quantitative leak testing of ductwork is limited to:

   a. All Primary Plant Ventilation System ductwork located above el. 873'-6" designated as Safety Class 3.

   b. All ductwork from the fresh air intake up to the Emergency Pressurization Units of the Control Room Air Conditioning System (CRACS).

   c. All ductwork related to the make-up air system from the fresh air intakes up to the isolation dampers (CPX-VADPOU-17, 18, 20, & 21) of the CRACS.

   d. All ductwork penetrating the Control Room envelope.

7. Part C.4.c, Ease of Maintenance:

   The spacing provided between the components of the filtration units is, in some cases, less than the minimum required by this regulatory position. However, it has been determined by operation and maintenance personnel that the spacing provided is sufficient to perform all required maintenance operations. This design conforms to the intent of Reg Guide 1.52, Revision 1 (07/76).

8. Part C.4.d, Test Probes:

   Test ports will be provided in lieu of permanently installed test probes. Permanently installed probes are a convenience in the periodic testing of filters and absorbers.

Replacing them with test ports is of no safety significance. This design meets the intent of NRC Regulatory Guide 1.52, Revision 1 (07/76).

9. Part C.5.b, Air flow distribution:

The air flow distribution to the HEPA filters and iodine absorbers will be tested in place for uniformity initially and after maintenance affecting the flow distribution for all units except the control room pressurization units.

10. Parts C.5.c and C.5.d, In-Place Testing Criteria:

ANSI/ASME N509-1980 and ANSI/ASME N510-1980 will be issued for field testing activities in place of the older versions of these codes referenced in this Regulatory Guide.

In-place testing of the HEPA filter banks and adsorber will be required following any significant painting, fire or chemical release described in position C.5.c and C.5.d of this guide. This design conforms to the intent of NRC Regulatory Guide 1.52, Revision 2 (03/78).

HEPA filter and charcoal adsorber efficiency for the Primary Plant Filtration Units is 95% which corresponds to an acceptance criteria of less than 1% for in-place penetration and bypass leakage at rated flow.

11. Part C.6, Laboratory Testing Criteria for Activated Carbon:

Laboratory testing of activated carbon will be in accordance with ANSI/ASME N509-1980, ANSI/ASME N510-1980 and ASTM-D3803-1989. The parameters applicable to new and used charcoal at CPNPP shall be applied in the lab test as follows:

New Charcoal	Used Charcoal
4" Beds[(a)]	4" Beds[(a)]
40 ft/min	40 ft/min
30°C & 95% RH	30°C & 70% RH
Pre-equilibrated	Pre-equilibrated

a) When the carbon sample is less than 4" (e.g., as a result of settling during shipment) the correction as detailed in ASTM D3803-1989 Section 9.2 may be applied.

The allowable methyl iodide penetration for 99% efficiency units (control room ventilation filtration and pressurization units) shall be 0.5% instead of 0.175% as shown in Table 2 of the Regulatory Guide.

The allowable methyl iodide penetration for 95% efficiency units (primary plant ventilation filtration ESF units) shall be 2.5% instead of 1.0% as shown in Table 2 of the Regulatory Guide.

When all or most of the charcoal canisters in the filtration units have been used, a representative sample of the charcoal from the bed will be obtained by grain thief sampling in accordance with ANSI N509-1980, Appendix A. The representative samples obtained with the grain thief will be used for laboratory testing and/or refilling the charcoal canisters.

The carbon adsorber beds will be replaced when (1) testing in accordance with the frequency specified in Footnote c of Table 2 results in a representative sample failing to pass the applicable test in Table 2 or (2) no representative sample is available for testing, at a time when testing is required.

This design conforms to the intent of NRC Regulatory Guide 1.52, revision 2 (03/78).

Regulatory Guide 1.53

Application of the Single-Failure Criterion to Nuclear Power Plant Protection Systems

Discussion

BOP systems meet the recommendations of this regulatory guide (dated June 1973) in accordance with the comments of Section 7.1.2.7.

Also refer to Appendix 1A(N).

Regulatory Guide 1.54

Quality Assurance Requirements for Protective Coatings Applied to Water-Cooled Nuclear Power Plants

Discussion

Protective Coatings inside containment were declassified from Nuclear Safety Related to Non-safety Related during construction, prior to the receipt of the Operating License. The protective coatings program is subject to a specifically structured quality assurance program as described in Appendix 17A.

A detailed “suitability of application review” of the protective coatings inside containment for Units 1 and 2 has been performed based on the guidance in EPRI Report 1003102 “Guideline on Nuclear Safety-Related Coatings”, Revision 1 (formerly TR-109937) and ASTM D 5144-00, Standard Guide for Use of Protective Coating Standards in Nuclear Power Plants. [ER-ME-124, Evaluation of CPNPP Protective Coatings] All of the protective coatings have been evaluated and classified as either “Acceptable” or “unqualified” coatings. This evaluation concluded that all of the applied protective coatings within both containment buildings are acceptable coatings with the exception of those coatings on the Coatings Exempt Log for each unit.

As of December 31, 2007, protective coatings inside containment are classified as Service Level I, coatings. The protective coatings program for ongoing Service Level I inspections, maintenance, repair and modifications is in accordance with the following guidance:

EPRI Report 1003102 “Guideline on Nuclear Safety-Related Coatings”, Revision1 (formerly TR-109937).

ASTM D 5144-00, Standard Guide for Use of Protective Coating Standards in Nuclear Power Plants.

For the above reasons, Regulatory Guide 1.54, “Quality Assurance Requirements for Protective Coatings Applied to Water-Cooled Nuclear Power Plants”, does not apply to Comanche Peak.

Also refer to Appendix 1A(N) and Section 6.1B.2 for further discussion.

Regulatory Guide 1.55

Concrete Placement in Category I Structures

Discussion

The CPNPP design and construction requirements and procedures for concrete placements in Category I structures are in conformance with the requirements of this regulatory guide dated June 1973.

Also refer to Section 3.8.

Regulatory Guide 1.56

Maintenance of Water Purity in Boiling Water Reactors

Discussion

This regulatory guide is not applicable to the CPNPP which has pressurized water reactor steam supply systems.

Regulatory Guide 1.57

Design Limits and Loading Combinations for Metal Primary Reactor Containment System Components

Discussion

The following is applicable to structural systems, i.e. air locks, equipment hatch, etc.

The design limits and loading combinations utilized for the CPNPP metal containment system components conform to the requirements of this regulatory guide dated June 1973.

Also refer to Section 3.8.

Regulatory Guide 1.58

Qualification of Nuclear Power Plant Inspection, Examination, and Testing Personnel

Discussion

With reference to the subject Regulatory Guide as it applies to activities during the Construction phase:

1. For inspection activities within the scope of the ASME Code, inspectors are qualified in compliance with the requirements of Regulatory Guide 1.58, Revision 1.

2. For inspection activities outside the scope of the ASME Code, inspection personnel are qualified in general compliance with the requirements of Regulatory Guide 1.58, Revision 1 except as follows:

    a. Some inspection personnel qualifications are documented on a TUGCO form and not on the Constructor's form.

    b. Some of the qualification forms are signed by a TUGCO representative and not by a Constructor representative.

3. Qualification records are collected, stored and controlled in compliance with ANSI N45.2.9 Draft 11, Revision 0 dated January 17, 1973 as included in the "Gray Book".

For Operational Phase activities, CPNPP Vistra OpCo will comply with the provisions of Regulatory Guide 1.58, Revision 1, for the qualification of quality control inspection personnel.

Also refer to Appendix 1A(N) and Section 17.2.

Regulatory Guide 1.59

Design Basis Floods for Nuclear Power Plants

Discussion

The CPNPP probable maximum flood (PMF) analysis was done prior to the issuance of R.G. 1.59. However, a detailed examination has shown that it complies with revision 2 (8/77) of this regulatory guide except as noted below:

Revision 2 of this guide differs, in part, from revision 1 in that it refers to ANSI Standard N170-1976. The CPNPP PMF analysis differs slightly from the recommended methods in ANSI N170-1976 in three areas.

The probable maximum precipitation (PMP) used in the CPNPP analysis is based on Hydrometeorological Report (HMR) No. 33. ANSI N170 - 1976 refers to HMR 33 and also to a draft version of the later HMR 51. The use of HMR 33 PMP data instead of HMR 51 has only a small effect on the calculated high water levels.

The CPNPP PMF analysis used a rainfall time distribution slightly different from the time sequence recommended by ANSI N170 - 1976. This results in no significant difference in calculated maximum water height in either the reservoir or Safe Shutdown Impoundment.

ANSI N170 - 1976 recommends using an antecedent rainfall preceding or following the PMF. The CPNPP analysis assumed the reservoir is full to the top of the conservation storage. The assumption of antecedent rainfall results in slightly higher calculated maximum water levels.

The combined effect of the three computational differences above results in calculated maximum water elevations that are within design limits. Specifically, the resulting minimum freeboard values are in excess of the required freeboard heights for protection against wave action at the peak of the flood.

Regulatory Guide 1.60

Design Response Spectra for Seismic Design of Nuclear Power Plants

Discussion

The design response spectra for the seismic design of the CPNPP plant is in conformance with Revision 1 (12/73) of this regulatory guide except in the high frequency region greater than 33 Hz of vertical response spectra where the vertical response spectra are reduced to a maximum vertical ground acceleration of 0.08g at 50 Hz. This exception is in accordance with NRC Standard Review Plan, Section 3.7.1 and is also consistent with the recommendation of Newmark, Blume and Kapur (Reference 14 of Section 3.7B) from which the vertical design response spectra of this regulatory guide was developed. Similarly, vertical response spectrum frequency of 4.0 Hz was recommended by Newmark, Blume and Kapur and used here instead of 3.5 Hz adopted in Regulatory Guide 1.60. The effect of these deviations is insignificant.

Also refer to Appendix 1A(N).

Regulatory Guide 1.61

Damping Values for Seismic Design of Nuclear Power Plants

Discussion

The damping values utilized for the seismic design of the CPNPP are in conformance with this regulatory guide dated October 1973. For piping systems analyzed by the response spectrum method, ASME Code Case N-411 damping values may be used in lieu of the damping values in this Regulatory Guide.

Also refer to Appendix 1A(N) and Section 3.7B.

Regulatory Guide 1.62

Manual Initiation of Protective Actions

Discussion

Manual initiation controls for BOP systems meet the recommendations of this Regulatory Guide in accordance with the comments of Section 7.3.2.2.7. System level manual actuation of BOP components (such as the auxiliary feedwater pumps, containment spray pumps, component cooling water pumps, etc.) is accomplished through the system level actuation devices described in Section 7.3.2.2.7, for manual initiation of safety injection, spray actuation, or steam line isolation, as appropriate to the component.

Also refer to Appendix 1A(N).

Regulatory Guide 1.63

Electric Penetration Assemblies in Containment Structures for Light-Water-Cooled Nuclear Power Plants

Discussion

The CPNPP Electric Penetration Assemblies comply with the intent of Revision 2 (7/78) of this regulatory guide. For details see Section 8.3.

Regulatory Guide 1.64

Quality Assurance Requirements for the Design of Nuclear Power Plants

Discussion

The quality assurance program for design and construction at CPNPP incorporates the intended objectives of ANSI N45.2.11 (Draft 2, Revision 2 - 5/73). The quality assurance methods for operation phase activities will comply with applicable guidance contained in Revision 2 (6/76) of this regulatory guide. The application of the requirements of ANSI N45.2.11 - 1974, as endorsed by this regulatory guide, will be in accordance with the guidance provided by ANSI N18.7 - 1976.

Also refer to Appendix 1A(N) and Section 17.2.

Regulatory Guide 1.65

Materials and Inspections for Reactor Vessel Closure Studs

Discussion

Refer to Appendix 1A(N).

Regulatory Guide 1.66

Nondestructive Testing of Tubular Products

Discussion

This regulatory guide was withdrawn September 28, 1977.

Regulatory Guide 1.67

Installation of Overpressure Protection Devices

Discussion

This regulatory guide was withdrawn by the NRC on April 15, 1983 because the Winter 1978 Addenda to the 1977 edition of the ASME Boiler and Pressure Vessel Code, Appendix O, Section III, Division 1, included requirements equivalent to the recommendations in this Reg. Guide. The NRC accepted these changes in the code by reference in 50.55a of 10CFR50 (46FR20153) on April 3, 1981.

Regulatory Guide 1.68

Preoperational and Initial Startup Test Programs for Water-Cooled Power Reactors

Discussion

The testing activities conducted as part of the Initial Test Program, as described in Section 14.2, and startup program comply with the intent of this Regulatory Guide, Revision 2, dated August 1978, with the following exceptions and justification.

1. Appendix A subparagraph 1.c

   As identified in Table 14.2-2, Sheet 42A of 60 of the FSAR, the response time acceptance criteria of the various logic channels will be consistent with Technical Specifications requirements. The Reactor Trip System Response Time is defined in the technical specifications as the time interval from when the monitored parameter exceeds its trip setpoint at the channel sensor until loss of stationary gripper coil voltage. The accident analysis accounts for conservative values for delay times, setpoint drift, etc. Therefore, it is not necessary to account these delay times in the test methods or acceptance criteria.

2. Appendix A subparagraph 1.d.1, 1.e.6, 1.e.g, 1.f.1, 1.j.2 & 1.j.17

   There are no safety related functions of the turbine control and bypass valves as discussed in FSAR Section 10.2.2.7.7. The circulating water system also has no safety related function as described in FSAR Section 10.4.5. Therefore these systems are not included in the preoperational program. However, as identified by Section 14.2.1 these systems are intended to be acceptance tested in accordance with applicable startup administrative procedures.

   The feedwater control system is not required for safety but does have an interface with the protective system. These interfaces are exclusively part of the feedwater isolation valves ability to close upon the actuation of the proper logic and is covered within preoperational test summary FSAR Table 14.2-2, Sheet 50.

3. Appendix A subparagraph 1.d.3

The accident analysis concerning the inadvertent depressurization of the reactor coolant system is discussed in FSAR Section 3.9N.1.1, Upset Condition number 5. Subsection 5.b lists the condition of the inadvertent opening of one pressurizer power operated relief valve (PORV). The analysis states that the limiting case is the actuation of the pressurizer safety valve. This is classified as an Upset Condition with no operational impairment. The design parameters listed in Table 5.4-16 of the FSAR indicate that the relieving capacity for the pressurizer power operated relief valve is one-half the capacity of the pressurizer safety valve, 210,000 lb/hr vs 420,000 lb/hr. Therefore there is no intention of performing capacity tests of the pressurizer power operated relief valves during the startup phase.

Testing of these valves is listed in Table 14.2-2, Sheet 53, of the FSAR as a preoperational test.

The accident analysis covering the opening of a steam generator power operated relief valve is similar. The analysis is described in FSAR Section 15.1.4. This accident analysis uses a value of 968,400 lbm/hr @ 1200 psia. In addition, for plant cooldown requirements, a minimum capacity of 62,150 lbm/hr @ 100 psia is also required. Table 10.3-3 in the FSAR describes these requirements. Because of extensive validation program conducted by the valve vendor, the uncertainties associated with a field test and the routine calibration of the valve stem travel stop positions, there is no need to test the capacities of the steam generator power-operated atmospheric relief valves during the startup program.

The testing of the steam generator power operated relief valves is presented in FSAR Table 14.2-2, Sheet 49.

4. Appendix A subparagraph 1.k.2,3

The equipment identified in the above paragraphs of Regulatory Guide 1.68 is calibrated and functionally tested as part of the instrument calibration program for the TUGCO Chemistry and Health Physics section. The calibration and functional testing is performed and documented in accordance with approved station calibration procedures. Therefore, TUGCO Startup will not perform additional testing, in the form of a preoperational test, on this equipment.

5. Appendix A subparagraph 1.n.11

Refer to the discussion of Regulatory Guide 1.68.3.

6. Appendix A subparagraph 1.o.1

The vendor has performed applicable load testing on the head lifting and internals lifting devices for 125% static loads.

7. Appendix A subparagraph 4.t

Natural circulation tests have been successfully completed at McGuire Unit 1, Salem 2, Sequoyah 1 and other Westinghouse plants similar to CPNPP. It is unnecessary for CPNPP to compare flow (without pumps) and temperature data to that of these plants

since no design differences exist which would significantly effect natural circulation capabilities. Typical natural circulation characteristics for 4 loop Westinghouse plants are given in WCAP-8460, “Natural Circulation Test Report for Zion Station Unit 1.” However, in order to verify natural circulation cooldown and boron mixing capability per requirements of Branch Technical Position RSB 5-1, CPNPP referenced test results from Diablo Canyon Unit 1 which were found to be acceptable. See Appendix 5A for further discussion.

8. Appendix A subparagraph 5.k.k

The most influential contributor for this transient is the value of moderator temperature coefficient of reactivity, which has a relatively low value at beginning of core life. Since this parameter is determined in other startup tests, thus validating the safety analysis, the performance of this test provides no new information needed to verify the plant design. The transient does introduce the potential for thermal stress damage to the steam generator feedwater inlet nozzles and it expends one of the analyzed thermal cycles. Therefore, we do not intend to perform a test to comply with this subparagraph.

9. Appendix A, Subparagraphs 4c, 5e, 5f and 5i

The pseudo ejected rod tests and pseudo dropped rod tests referenced by these sections of the Regulatory Guide have been successfully performed at plants of similar design to Comanche Peak. Previous tests on similar facilities indicate little new information is generated by the performance of these tests. Additionally, vendor predictions indicate that a violation of the F-delta-H Technical Specification may occur if the 50% power pseudo dropped rod test is performed at Comanche Peak. Recent industry experience indicates there is an increased potential for causing severe xenon transients by performing these tests. Based on these reasons, we do not intend on performing tests to comply with Appendix A, Subparagraphs 4c, 5e, 5f and 5i. A normal function of the Digital Rod Position Indication system is to detect misaligned control rods which satisfies subparagraph 5i. The Digital Rod Position Indication system is a diverse and independent method of detecting control rod positions.

10. Appendix A, subparagraph 5.d.

CPNPP plant design does not include part-length control rods. The ability to control core xenon transients is a design feature of the Westinghouse Nuclear Steam Supply System and has been demonstrated in numerous operating pressurized water reactors. In addition, compliance with Technical Specification 3/4.2.1, “Axial Flux Difference”, ensures proper power and flux distributions. On these bases, CPNPP does not intend to perform an Initial Startup Test to comply with subparagraph 5.d.

11. Appendix A, subparagraph 5.i.i.

The performance of this test provides no new information needed to verify the plant performance during design transients. Trip of the reactor coolant pumps result in a reactor trip with flow coastdown, as verified in the Reactor Coolant System Flow Coastdown Test, providing sufficient heat removal to ensure DNBR does not decrease below the limit value. Performing this test expends one of the analyzed transients and results in unnecessary cost and down time for the utility.

12. Appendix A, subparagraph 5.u.

Operability and response times of the main steam isolation valves will be verified in hot standby (mode 3) rather than at the recommended 25% power level. Testing at hot, zero power will result in more conservative results and will eliminate the unnecessary pressure and steam flow transients which would otherwise be induced.

13. Appendix A, subparagraph 5.m.m.

The performance of this test provides no new information needed to verify the plant performance during design transients. Closure of all Main Steam Isolation Valves from 100% power causes a turbine trip and a reactor trip. A turbine trip and reactor trip from 100% power will be performed during initial startup testing. Closure of the MSIV's may cause the operation of the pressurizer and steam generator power operated relief valves and/or safety valves which may then require repair and unnecessary down time for the utility. This test would expend one of the analyzed pressure transients for the reactor coolant system and steam generators and therefore will not be performed at CPNPP.

14. Appendix A, subparagraph 2.b

Hot no flow, cold no flow and cold full flow rod drops do not provide any additional useful data. By Technical Specifications, critical operations are only permitted when plant is hot and RCP operating and thus scram testing is not required for hot no flow, cold no flow and cold full flow conditions. We do not intend to take credit for cold no flow, cold full flow and hot no flow rod drops, although one or more of these tests may be optionally performed for diagnostic or demonstration purposes.

15. Appendix A, subparagraph 5.h

Rod drop times are measured during pre-critical testing at hot full-flow conditions. There is no provision in the design of CPNPP to allow for determination of rod scram times following normal plant trips. These tests meet the intent of subparagraph 5.h.

16. Appendix A, subparagraph 5.j

The CPNPP design does not include partial scram or rod runback features. Therefore, an Initial Startup Test will not be performed to comply with subparagraph 5.j.

17. Appendix A, subparagraph 5.l

The CPNPP residual heat removal (RHR) system does not include a "steam condensing mode" of operation. Also, the "reactor core isolation cooling (RCIC) system" pertains to Boiling Water Reactors. Since these features do not exist at CPNPP, they cannot be tested during the Initial Startup Test program. The remainder of paragraph 5.l will be complied with.

18. Appendix A, subparagraph 5.a

The power coefficient measurement test method recommended by Westinghouse cannot be used because it requires installed instrumentation (narrow range hot leg temperature)

which is not part of CPNPP design. Power coefficient measurement results, obtained during the startup of several Westinghouse plants, have verified consistency between design calculations and measurement data in plants having fuel similar to the Comanche Peak design. CPNPP's Initial Startup program includes measurement of the critical RCS boron concentration under the conditions of all rods out, hot full power, equilibrium xenon. From this, the core reactivity balance is verified. This test is considered sufficiently accurate to detect any significant differences between the designed and as-built core. This test is in addition to the minimum specifications of the Regulatory Guide.

19. Appendix C, subparagraph 4.h.

The power ascension program for CPNPP requires flux maps to be taken at each power plateau. The values for $F_Q(Z)$ (heat flux hot channel factor) and $F^N{}_H$ (nuclear enthalpy rise hot channel factor) obtained from these flux maps will be compared to and evaluated against Technical Specification limits. This evaluation will be used in place of extrapolating DNBR and linear heat rate values. This action is consistent with the Reference Startup Document supplied by the fuel vendor. Station Administrative procedures will require management review and approval of test results prior to ascending to the next power plateau.

20. Section C.8, Appendix A (Various)

Testing will not be performed at the Regulatory Guide suggested 25% (30%) power. Testing originally specified at 30% RTP will be conducted at 50% RTP. Where testing had been previously performed for both 30% and 50% RTP, only the 50% RTP test will be performed.

The tests that were previously prescribed to be conducted at the 30% rated thermal power (RTP) plateau include the following:

Core Performance Evaluation
Unit Load Transients (10% Step Load Change)
Automatic Reactor Control System Test

The core performance data that could be obtained at 30% RTP is utilized for gross calibration adjustments of the Nuclear Instrumentation System (NIS) prior to power escalation to 50% RTP. This activity will be performed at 25-30% RTP as a hold prior to escalation to 50% RTP. The flux distribution measurement at 30% RTP will not be performed unless the peaking factors measured at low power do not support escalation to 70% RTP, the NIS trip setpoint for the 50% RTP testing plateau. This is per the direction of RG-1.68 Appendix C, paragraph 4.h.

For Unit 2, one low power flux map will be taken prior to exceeding 30% RTP as a fulfillment of Regulatory Guide 1.68, Appendix A, subparagraph 4.e. At power, flux maps will be taken at 50%, 75% and 100% RTP to satisfy Regulatory Guide 1.68, Appendix A, subparagraph 5.b. Additional flux maps will be taken if required by Regulatory Guide 1.68, Appendix C, subparagraph 4.h.

For Unit 1, the unit load transient at approximately 30% RTP will be performed following completion of 50% RTP plateau testing to assure proper control system response. For Unit 2, the 30% RTP unit load transient will not be performed.

The Automatic Reactor Control System test is performed at 50% RTP and intended as a precursor to the first Unit Load Transient test. It is designed to ensure that the automatic rod control system can restore the Reactor Coolant System (RCS) temperature to within a +1.5 Deg-F deadband of the reference temperature. Prior to 50% RTP, proper operation of this function would be demonstrated by observation during the normal power escalation, where the control rods will be in automatic and already controlling the RCS temperature to within the deadband.

21. Appendix A, subparagraph 5.z

For Unit 2, each radiation monitor and detector will be calibrated in lieu of only verifying response to a radiation check source as part of the preoperational test program (Table 14.2-2, Sheet 24A). The calibration of the monitors and detectors meet the intent of RG 1.68, Revision 2, Appendix A, Sections 4.g and 5.z (see FSAR 11.5.2.11) and provides a more accurate method for demonstration of their proper operation.

22. Appendix A, subparagraph 1.j.(13).

The incore neutron instrumentation portion of this subparagraph cannot be fully tested as a preoperational test program item because the system is not fully installed until after initial fuel load. The fuel assemblies provide the structural support for the incore flux mapping system thimbles, the thimbles are not self-supporting and cannot be installed until after the fuel is all in place. For this reason, the only valid demonstration of proper system function over its full operational range must be performed after initial fuel load. Portions of this testing are also customarily performed at normal operating temperatures prior to initial reactor criticality to ensure that thimble thermal expansion does not create any system operation interferences.

23. Appendix A, subparagraph 1.j.(18).

The neutron response checks of the auxiliary startup instrumentation are not included as part of the preoperational test program. This testing is performed prior to the start of initial fuel loading, but is addressed as an initial startup test. The auxiliary startup instrumentation is typically received only a short time prior to the start of initial fuel load and is tested prior to the actual fuel movements. The neutron response check portion of this testing is required to be performed within 8 hours of the actual start of initial fuel loading. This time constraint makes it impractical to retain this testing in the preoperational testing program as it allows too little time to close out the preoperational testing program prior to fuel load.

24. Appendix A, subparagraph 5.q.

The failed fuel detection system consists of the failed fuel monitor with letdown chemistry samples used as both a backup and supplement. The failed fuel monitor, itself, is one of

the process radiation monitors that are tested elsewhere under subparagraph 5.z. Additional testing of this one monitor, beyond that already planned as part of the process monitor testing, would not be expected to provide additional useful test results. Normal plant operating surveillances provide sufficient assurance of failed fuel monitor operability and of the ability to detect any actual failed fuel.

Regulatory Guide 1.68.1

Preoperational and Initial Startup Testing of Feedwater and Condensate Systems for Boiling Water Reactor Power Plants

Discussion

This regulatory guide is not applicable to the CPNPP

Regulatory Guide 1.68.2

Initial Startup Test Program to Demonstrate Remote Shutdown Capability for Water Cooled Nuclear Power Plants

Discussion

The testing activities conducted as a part of the startup test program will comply with the applicable requirements of Revision 1 (7/78) of this regulatory guide.

Also refer to Section 14.2.

Regulatory Guide 1.68.3

Preoperational Testing of Instrument Air Systems

Discussion

The CPNPP Instrument Air System testing meets with the intent of the requirements of NRC Regulatory Guide 1.68.3, Regulatory Positions C.1 through C.11, as described below:

Position C.1: CPNPP meets the intent of position C.1 by performing preoperational tests on those aspects of the system which are important to safety as described in Section 14.2. The balance of the Instrument Air System testing is performed under the acceptance testing program at CPNPP.

Position C.7: Air operated components which are required to operate in order to perform a safety function are provided with safety related air accumulators as described in section 9.3.1.1. These accumulators and their associated check valves are, for the purposes of single failure analysis, considered an extension of the component being supplied. In no case are safety related air accumulators shared between two redundant components. Therefore, CPNPP meets the required single failure criterion. Tests on these accumulators are described in FSAR Section 14.2.

Position C.8: Preoperational tests for loss of Instrument Air are performed as described in FSAR Section 14.2. Prerequisite tests are performed to verify air operated component failure positions. This testing meets the intent of position C.8.

Position C.9: Regulatory Position C.9 is not applicable to CPNPP since there is no provision for connecting the plant Service Air System to the Instrument Air System.

Position C.10: Regulatory Position C.10 addresses air header pressure transients caused by large air users. The CPNPP Instrument Air Systems only bulk load is the Turbine Generator Gas Purge. This function is manually initiated and is only used while the plant is not operational. To date, operation of the Turbine Generator Gas Purge has not revealed any problems associated with pressure transients. Therefore, no testing will be performed.

Position C.11: Regulatory Position C.11 addresses Instrument Air System overpressure transients. The CPNPP Instrument Air System is protected from overpressurization by relief valves which are individually tested. No additional overpressure testing is performed.

Also refer to Section 14.2

Regulatory Guide 1.69

Concrete Radiation Shields for Nuclear Power Plants

Discussion

The regulatory guide states that ANSI N101.6-1972, Concrete Radiation Shields, is considered applicable to shielding structures for nuclear power plants, subject to certain conditions. These conditions are stated in Regulatory Positions Nos. 1-8 of the regulatory guide. The guidance provided in this regulatory guide, dated December 1973, is adhered to as follows:

1. Regulatory Position No. 1: The codes and standards of concrete shielding are those listed in subsection 3.8.4.2 (outside the Containment).

2. Regulatory Position No. 2: This position is complied with as described in Section 3.8.

3. Regulatory Position No. 3: In the design of concrete radiation shields, there has been consideration of steady state and transient thermal loads and loads due to postulated missiles, as described in Sections 3.3, 3.8.3.3, and 3.8.4.3.

4. Regulatory Position No. 4: This position is complied with as described in Sections 3.8.3 and 3.8.4.

5. The intent of Regulatory Position Nos. 5 and 6 is complied with.

6. Regulatory Position No. 7: Provision is made for adequate means by transferring all forces through construction joints. All loads described in Sections 3.3, 3.5, and 3.8 are considered in the design.

7. Regulatory Position No. 8: Vacuum box testing of pool liner welds, or an equivalent alternate method, are considered as an acceptable supplementary method of testing liner welds or leaktight integrity.

Also refer to Section 12.3.2.

Regulatory Guide 1.70

Standard Format and Content of Safety Analysis Reports for Nuclear Power Plants, LWR Edition

Discussion

The CPNPP FSAR conforms to the format of Revision 2 (9/75) of this regulatory guide with minor variations where needed for clarity. In a number of sections the NSSS information is separated from the BOP (i.e. 1A(N) and 1A(B), 3.6N and 3.6B). Appendices are used appropriately and incorporated by reference.

Printing/reproduction for FSAR amendments may be performed mechanically or photographically, including “Xerox-type” copier quality reproduction.

Following clarification is provided for Revisions Section (Page V):

Amendment number and date of change is provided on each affected pages of Sections and Tables. For flow diagrams, it will be provided on the index pages in lieu of each flow diagram.

Regulatory Guide 1.71

Welder Qualification for Areas of Limited Accessibility

Discussion

The CPNPP design complies with the requirements of this regulatory guide, dated December 1973, for piping only.

Also refer to Appendix 1A(N).

Regulatory Guide 1.72

Spray Pond Plastic Piping

Discussion

This regulatory guide is not applicable to the CPNPP.

Regulatory Guide 1.73

Qualification Tests of Electric Valve Operators Installed Inside the Containment of Nuclear Power Plants

Discussion

Safety-related motor operated valves inside Containment comply with the guidance of Regulatory Guide 1.73, dated January 1974, with the exception that stem mounted limit switches are tested separately to the requirements of IEEE Standard 382-1972.

For details see Section 3.11B.

Also refer to Appendix 1A(N).

Regulatory Guide 1.74

Quality Assurance Terms and Definitions

Discussion

This guide is not applicable to CPNPP design and construction. The quality assurance provisions for operating phase activities are in accordance with the guidance of ANSI N45.2.10 - 1973, as endorsed by this regulatory guide dated February 1974.

Also refer to Section 17.2.

Regulatory Guide 1.75

Physical Independence of Electric Systems

Discussion

CPNPP design complies with the intent of Revision 1 (1/75) of this regulatory guide with the following comments:

Regulatory Position C.1 - Non-Class 1E power or control circuits may be isolated from their Class 1E power source by two circuit breakers, two fuses or a breaker and a fuse in series, both coordinated with an upstream circuit protective device, and the circuit breakers periodically tested. Non-safety instrument circuits powered from distribution panels 1PC1, 1PC2, 1PC3, and 1PC4 will have a non-safety circuit breaker or fuse connected in series with the panel circuit breaker.

The non-Class 1E AC essential lighting circuits use interconnecting cable (i.e., from the distribution panel feeder breaker to the lighting load) routed in conduit. The routing of the circuits in conduit ensures the physical and electrical independence from Class 1E circuits beyond the isolation breaker.

The non-Class 1E DC emergency lighting circuits connected to dedicated batteries are routed in conduit. The routing of the circuits in conduit ensures physical and electrical independence from Class 1E circuits.

The lighting circuits routed in conduit meet the separation criteria of FSAR Section 8.3.1.4.

Electrically, Class 1E circuits are equal or superior to non-Class 1E circuits. Physically, Class 1E circuits are subject to more stringent analysis than non-Class 1E circuits. Therefore, devices qualified for non-Class 1E-to-Class 1E isolation applications provide more than adequate train-to-train isolation.

Separation between Radiax and Heliax radio antenna cables and Class 1E cables is not required. The analysis is provided in Section 8.3.1.4(4).

Separation between Thermistor and Class 1E cables is not required. The analysis is provided in Section 8.3.1.4(4).

Fiber optic cables used in non-Class 1E monitoring circuits carry no electrical energy by themselves and therefore are not required to maintain physical separation from Class 1E circuits.

Lesser internal wiring separation is being used between redundant safety systems and safety and non safety systems in BOP Analog Process Instrumentation Panels. This analysis is provided in Section 7.1.2.2.

The non-Class 1E diesel generator neutral grounding transformer is connected to the neutral of the Class 1E diesel generator. An analysis has been performed which demonstrates that a fault on the non-Class 1E portion of the circuit will not cause an unacceptable influence on the Class 1E system. In addition, the interconnecting cable is routed within the diesel generator room. The cable is routed in dedicated raceway and is inspected to Class 1E requirements.

Isolation between Non-Class 1E cables originating from Non-Class 1E, 6.9kV switchgear reactor coolant pump and potential transformer Class 1E fuse, is not required based on the analysis provided in Section 8.3.

Isolation between the Class 1E pressure indicating switch contact and Non-Class 1E time delay relay contact in Emergency Diesel Generator control panels CP1-ECCPEC-01 and 02 is not required based on the analysis provided in Section 8.3.

Isolation between Non-class 1E cables originating from the annuniciator in Spent Fuel Pool Panel CPX-EIPRLV-06 and Class 1E electronic boxes X-LY-4849A and B is not required based on the analysis provided in Section 8.3.

Isolation between the Non-Class 1E coaxial cable and the epoxy mica capacitor (EMC) which forms part of the Class 1E Partial Discharge Monitor Bus Coupler connected to each of the Unit 1 and Unit 2 Station Service Water Pump and Component Cooling Water motor feeders and Emergency Diesel Generators, is not required based on the analysis provided in Section 8.3.

Regulatory Position C.2 - For the purpose of electrical cable separation, acceptable barriers include rigid metal conduit, electrical metallic tubing (EMT), flexible metallic conduit, cable tray covers (both solid and ventilated types), cable bus enclosures, equipment and device enclosures, enclosed metal wireways inside equipment, a wrap of woven silicon dioxide and one hour fire rated materials (i.e. thermolag and one hour fire rated cable).

A wrap of woven silicon dioxide, thermolag and one hour fire rated cable are considered equivalent to a metal enclosed raceway with respect to protection from electrical failures.

Thermolag and one hour fire rated cable shall only be used as a Regulatory Guide 1.75 electrical separation barrier when installed to satisfy the requirements described in FSAR Section 9.5.1.2.

Metal Clad (MC) cables include copper sheathed (CS) cable, aluminum sheathed (ALS) cable and Galvanized Steel Sheathed Cable (GS). MC cables are considered the same as cable inside conduit for separation purposes. See Section 8.3 for the analysis and discussion on MC cables.

CS cable is constructed of continuous corrugated 16 mil thick copper tube with no outer jacket and 600V XHHW, 90°C insulation. CS cable will be used only inside the containment and only in the lighting system.

ALS cable is constructed of continuous corrugated 25 mil. thick seamless aluminum tube with an outer thermosetting chlorosulphonated polyethylene jacket and 600V XHHW, 90° C insulation. ALS cable will only be used outside of the containment building in the lighting, fire protection, heat tracing and communication systems.

The one hour fire rated cable provides a one hour fire rated barrier per ASTM standard E 119-1971. The cable is Class 1E qualified per IEEE 323-1974 and IEEE 383-1974 for flame retardancy (unaged cables only). See FSAR Section 1A(B), Regulatory Guide 1.131. The cable is constructed of a continuously welded corrugated 12 mil thick stainless steel sheath with high temperature nickel-clad copper conductors, glass braid cable jacket and silicone rubber insulation. This cable will be used to satisfy the fire safe shutdown requirements, as described in FSAR Section 9.5.1.2, in power and control circuits outside containment where the total radiation dose is less than or equal to 50 MRADS gamma. Cable sizes will be and smaller. The cable is considered equivalent to cable in conduit for electrical separation purposes.

Regulatory Position C.4 - The multiconductor cable between the Safety System Inoperable Indication (SSII) logic panel located in the control room and the termination cabinet in the cable spreading room meet the requirements of this position except for Class 1E environmental qualification. The cable materials meet IEEE Standard 383-1974 for the attributes of flame and radiation resistance. The cable is installed in a mild environment. Based on analysis, a fault at the SSII logic panel will not impact the availability of adjacent Class 1E cables with which these associated cables are routed. This analysis is provided in Section 8.3.

Regulatory Position C.6 - Lesser separation, based on RG 1.75 Rev. 3, is being used for interaction involving instrumentation cables only. This analysis is provided in Section 8.3.

Lesser separations are being used in several locations between Class 1E wiring and non-Class 1E Area Radiation Monitoring detector wiring and Public Address System speaker wiring based on analysis. This analysis is provided in Section 8.3.

Separation between Class 1E circuits and non-Class 1E Emergency Diesel Generator stator RTD circuits is not required based on analysis. This analysis is provided in Section 8.3.

Separation between Class 1E Cables and Non-Class 1E cables at the Electronics Boxes (X-LY-4849A-1, X-LY-4849A-2, X-LY-4849B-1 and X-LY-4849B-2) furnished by FCI is not required based on analysis. This analysis is provided in Section 8.3.

Separation between associated circuits and non-Class 1E circuits in fire panels CPX-EIPRLV-29, CPX-EIPRLV-29A, and CPX-EIPRLV-30 is not required based on analysis. This analysis is provided in Section 8.3.

Separation between associated cables and non-Class 1E cables at the Safety System Inoperable Indication panels is not required based on analysis. This analysis is provided in Section 8.3.

Separation between the output circuits of the spare inverters is not required based on the analysis provided in Section 8.3.

Separation between non-Class 1E cables originating from 6.9kV switchgear (Reactor Coolant Pump) and Class 1E PT fuses inside the Class 1E PT cabinet is not required based on the analysis. This analysis is provided in Section 8.3.

Separation between associated cables and non-Class 1E Regulating transformers TXEC1, TXEC2, TXEC3 and TXEC4 is not required based on analysis. This analysis is given in Section 8.3

Separation between associated cables and non-class 1E cable CP2-EIPRLV-48 is not required based on analysis. This analysis is given in section 8.3.

Minimum physical separation between class 1E cables and nonclass 1E differential relay (87/ST1 and 87/ST2) protection cables are not required inside the 6.9 kV class 1E switch gear based on analysis. This analysis is provided in Section 8.3.

Separation between non-Class 1E Train C cables connected to the line and load terminals of breaker CP1-BSDSEB-01, CP2-BSDSEB-01 and Class 1E Train B cables connected to the shunt trip coil are adequate to ensure that the non-Class 1E cabling will not degrade the Class 1E system based on analysis provided in Section 8.3.1.2.1.7.l.

When a cable, conduit or tray is protected by One-Hour Fire rated Thermo-lag installed to satisfy the requirements as described in FSAR section 9.5.1.2; there is no separation requirement from the Thermo-lag protected cable, conduit or tray, to the redundant cable, conduit or tray outside the Thermo-lag enclosure based on analysis. This analysis is provided in section 8.3.

Associated cables used to selectively connect the non-Class 1E alternate power diesel generators to the Class 1E 6.9kV switchgear are installed in outdoor raceway sections that are not seismically supported. These cables do not have Class 1E protection for over current and faults. This is based on the analysis provided in Section 8.3.

Separation/Isolation between associated control cables and non-Class 1E control cables at Instrument Air Compressor Termination Cabinet CP1-CICACO-01A is not required based on analysis. This analysis is provided in section 8.3.

Physical separation between non-Class 1E and Class 1E circuits or non-Class 1E and associated Class 1E circuits inside the Diesel Generator Engine Control Panels CP1/2-MEDGEE-01A/02A is not required based on the analysis provided in Section 8.3.1.4.5.

Regulatory Position C.9 - Splice type connections have been used to terminate field routed cables in raceways. Such splices are utilized in CPNPP design at:

1. Electric penetration assemblies (EPAs), Core Exit Thermocouple (CET) Integral Reference Junction (IRJ), Control Rod Drive Mechanism (CRDM) disconnect panel connectors and Electric Conductor Seal Assemblies (ECSAs) pigtail cables

2. Solenoid valves, limit switches, level switches, etc. (local mounted devices - LMDs)

3. Connection of LMDs to Electric Conductor Seal Assembly (ECSA) pigtails.

An analysis to justify cable splices in raceways is provided in Appendix 8A.

Regulatory Position C.10 - Cable jackets requiring field color coding are color coded at intervals not to exceed every 5 feet for exposed cable runs (cable not in raceway, i.e., cable not in cable tray, conduit or pull box) and at each end.

Regulatory Position C.12 - Power circuits for the following equipment located inside the Control Room complex, are routed in exclusive conduits within the Control Room complex:

Regulating transformers TXEC3 and TXEC4, and air conditioners CP1- VAACTC-01, CPX-VAACTC-01 and CP2-VAACTC-01.

The ratings of the above equipment do not categorize them as high energy equipment. Regulating transformers TXEC3 and TXEC4 and the air conditioners listed above are located in the Control Building Mezzanine Area, which is separated from the Control Room by a Seismic Category II partial height gypsum wall and concrete floor.

For details see Section 8.3.

Also refer to Appendix 1A(N).

Regulatory Guide 1.76

Design Basis Tornado for Nuclear Power Plants

Discussion

The CPNPP is designed to conform to the requirements of this regulatory guide, dated April 1974, except that it is designed to withstand the effects of a Design Basis Tornado having a maximum wind speed of 360 mph which is made up of a rotational speed of 300 mph and a translational speed of 60 mph. A simultaneous pressure drop of 3.0 psi at the rate of 1.0 psi per second is considered.

The Design Basis Tornado for CPNPP was determined prior to the issuance of this Regulatory Guide and was approved for use by the Atomic Energy Commission's Safety Evaluation Report Dated September 3, 1974.

Also refer to Section 3.3.

Regulatory Guide 1.77

Assumptions Used for Evaluating a Control Rod Ejection Accident for Pressurized Water Reactors

Discussion

The analysis of the radiological consequences of a control rod ejection accident presented in Section 15.4.8 follows the guidance provided in Regulatory Guide 1.195 instead of that in Regulatory Guide 1.77.

Regulatory Guide 1.78

Assumptions for Evaluating the Habitability of a Nuclear Power Plant Control Room During a Postulated Hazardous Chemical Release

Discussion

The CPNPP design meets the intent of this regulatory guide, dated June 1974, as discussed in Sections 2.2 and 6.4.

Regulatory Guide 1.79

Preoperational Testing of Emergency Core Cooling Systems for Pressurized Water Reactors

Discussion

The Initial Test Program, as described in Section 14.2, is in compliance with the provisions of Revision 1 (9/75) of this regulatory guide with the following exception.

1. Regulatory Position C.1.b(2)
   Recirculation Test - Cold Conditions

   A satisfactory in-plant test of the containment sump to demonstrate vortex control and acceptable pressure drops across screening and suction lines and valves was not practical for reasons which include physical limitations, difficulty of cleanliness control and the possibility of equipment damage.

   However, a full scale model of the Containment Recirc sumps, screens and surrounding area was used to demonstrate that unacceptable vortex formation in the sump area is precluded while simulating operation under various flow and pump combinations. In addition, the inlet loss coefficient across the sump screens and sump intake piping configuration was evaluated for comparison to analytically determined values and to verify the adequacy of new positive suction head at the pumps.

   The capability to realign valves and injection pumps to recirculate coolant from the containment floor was demonstrated. The full flow test was performed with the RHR pumps taking suction from the Refueling Water Storage Tank (RWST) and delivering to the RCS. The RHR pumps were not running when demonstrating the realignment capability. The net positive suction head was determined from the level in the RWST and

in the containment sump and shown to be greater than the required net positive suction head for the pump.

The lines from the containment sump to the RHR pumps were flushed and inspected to ensure that they are free from obstruction.

For details refer to Table 14.2-2, Sheet 15.

Regulatory Guide 1.80

Preoperational Testing of Instrument Air Systems

Discussion

Regulatory Guide 1.80 was superseded by Regulatory Guide 1.68.3.

Refer to the discussion of Regulatory Guide 1.68.3.

Regulatory Guide 1.81

Shared Emergency and Shutdown Electric Systems for Multi-Unit Nuclear Power Plants

Discussion

The CPNPP design complies with the provisions of Revision 1 (1/75) of this regulatory guide with an exception to Regulatory Position C1. For details see Section 8.3.1.2.1 Item 8.

Regulatory Guide 1.82

Sumps for Emergency Core Cooling and Containment Spray Systems

Discussion

The containment recirculation sump design in the CPNPP complies with the intent of the Regulatory Positions of this regulatory guide dated June 1974 with clarifications as noted below. The description and design evaluation of the containment recirculation sumps is provided in Section 6.2.2.

C.3 and C.8 - The screen design with (1) an outer trash rack and (2) a fine inner screen mounted on a structure with a solid top cover has been replaced by a strainer which incorporates the function of both the screen and the trash rack. The strainer is located on the lowest floor elevation in the containment exclusive of the reactor vessel cavity. The strainer is fully submerged prior to switchover of containment spray from injection to recirculation for LOCAs and secondary pipe breaks. This design meets the intent of the Reg. Guide.

C.4 and C.6 - The floor level in the vicinity of the sumps does not slope away from the sumps. However, the design meets the intent of the Reg. Guide by the provision of a one foot tall solid debris interceptor surrounding the sump strainers.

Regulatory Guide 1.83

Inservice Inspection of Pressurized Water Reactor Steam Generator Tube

Discussion

The inservice inspection of steam generator tubes complies with the intent of Revision 1 (7/75) of this regulatory guide.

Regulatory Guide 1.84

Design and Fabrication Code Case Acceptability ASME Section III Division 1

Discussion

Code cases listed in this regulatory guide will be used where appropriate.

By reference to ASME Section III requirements in the procurement specifications, the use of code cases by mechanical equipment suppliers requires mutual consent of the Owner or his agent and the manufacturer. The ASME Code Cases which are used for design and erection at CPNPP are identified in the appropriate mechanical design and erection specifications or the Brown & Root QA Manual; conditionally-approved Code Cases will show justification for their use, as required by NRC, in these documents. The application of ASME Code Cases is documented on the ASME Data Report Forms.

ASME Code Case N-31-1 regarding the use of elastomer diaphragm valves in ASME Class 2 and 3 applications has been applied to CPNPP. This Code Case was listed as having contingent approval in Regulatory Guide 1.84 Rev. 29 which was applicable when the Code Case was originally applied on April 15, 1994. The Code Case with the following conditions imposed by the Regulatory Guide should apply:

1. The service life of the elastomer should not exceed the manufacturer's recommended service life. This service life should not exceed 1/3 of the minimum cycle life established by the requirements of paragraph 3 of the Code Case. In addition, the service life of the elastomer diaphragm should not exceed 5 years.

2. The combined service life and storage life of the elastomer diaphragm should not exceed 10 years.

Also refer to Appendix 1A(N).

Regulatory Guide 1.85

Materials Code Case Acceptability ASME III Division 1

Discussion

Code cases listed in this regulatory guide will be used where appropriate.

By reference to ASME Section III requirements in the procurement specifications, the use of code cases by mechanical equipment suppliers requires mutual consent of the Owner or his agent and the manufacturer. The ASME Code Cases which are used for design and erection at CPNPP are identified in the appropriate mechanical design and erection specifications or the Brown & Root QA Manual; conditionally-approved Code Cases will show justification for their use, as required by NRC, in these documents. The application of ASME Code Cases is documented on the ASME Data Report Forms.

Also refer to Appendix 1A(N).

Regulatory Guide 1.86

Termination of Operating Licenses for Nuclear Reactors

Discussion

The termination of the operating license and subsequent decommissioning of the Comanche Peak Nuclear Power Plant will address the regulations in effect at that time.

Regulatory Guide 1.87

Guidance for Construction of Class 1 Components in Elevated-Temperature Reactors (Supplement to ASME Section III Code Cases 1592, 1593, 1594, 1595 and 1596)

Discussion

This regulatory guide is not applicable to the CPNPP.

Regulatory Guide 1.88

Collection, Storage, and Maintenance of Nuclear Power Plant Quality Assurance Records

Discussion

The quality assurance program for design and construction at CPNPP incorporates the intended objectives of ANSI N45.2.9 (Draft 11, Revision 0, 1/73). During the operations phase, the quality assurance methods and administrative controls utilized for controlling and storing QA records, as described in Section 17.2, will comply with the applicable guidance provided in ANSI N45.2.9 - 1974, as endorsed by Revision 2 (10/76) of this regulatory guide; except for paragraph 3 of section 5.6. For this exception, CPNPP will comply with paragraph 3 of section 5.6.1 of ANSI N45.2.9-1979, which requires a minimum two hour rating for the structure, doors, frames and hardware of the storage facility. Application of the requirements of Revision 2 (10/76) of this regulatory guide will be in accordance with the guidance provided in ANSI N18.7 -1976.

To ensure adequate protection and timely processing of quality related documentation prior to transmittal of this documentation to the permanent records storage facility for retention, the following control measures shall be implemented in accordance with approved procedures:

1. Within 60 days from the time that the work activity was completed, quality related documentation shall be processed through any required post work or closure reviews and transmitted to the permanent records storage facility for retention;

2. Once the work activity has been completed, the associated quality related documentation shall be provided adequate protection from damage, deterioration, loss and unauthorized alteration.

Also refer to Section 17.2.17.

Regulatory Guide 1.89

Qualification of Class IE Equipment for Nuclear Power Plants

Discussion

The CPNPP Class 1E equipment design complies with the qualification program guidelines as delineated in this regulatory guide dated November 1974. However, as supported by the statements of consideration for 10CFR50.49 (Federal Register, 48FR2731, January 21, 1983), the recommendations of this regulatory guide need not be applied for Class 1E equipment located in a mild environment area.

Also refer to Appendix 1A(N).

Regulatory Guide 1.90

Inservice Inspection of Prestressed Concrete Containment Structures with Grouted Tendons

Discussion

This regulatory guide is not applicable to the CPNPP.

Regulatory Guide 1.91

Evaluation of Explosions Postulated to Occur on Transportation Routes Near Nuclear Power Plant Sites

Discussion

No transportation routes in the vicinity of CPNPP are within the distances established by this regulatory guide dated January 1975.

Revision 1 (2/78) of this guide is addressed in Section 2.2.3.

Regulatory Guide 1.92

Combining Modal Responses and Spatial Components in Seismic Response Analysis

Discussion

Modal responses and spatial components are combined in the seismic response analysis of the CPNPP in conformance with Revision 1 (2/76) of this regulatory guide.

Also refer to Appendix 1A(N) and 3.7B.

Regulatory Guide 1.93

Availability of Electric Power Sources

Discussion

The CPNPP design complies with the requirements of this regulatory guide dated December 1974.

Also refer to Section 8.3.

Regulatory Guide 1.94

Quality Assurance Requirements for Installation, Inspection, and Testing of Structural Concrete and Structural Steel During the Construction Phase of Nuclear Power Plants

Discussion

This regulatory guide is not applicable to CPNPP design and construction activities. The quality assurance methods for operations phase activities will comply with applicable guidance contained in Revision 1 (4/76) of this regulatory guide. The application of the requirements of ANSI N45.2.5 -1974, as endorsed by this regulatory guide, will be in accordance with the guidance provided in ANSI N18.7 - 1976.

Also refer to Section 17.2.

Regulatory Guide 1.95

Protection of Nuclear Power Plant Control Room Operators Against an Accidental Chlorine Release

Discussion

The CPNPP design complies with the intent of Revision 1 (1/77) of this regulatory guide as described in Section 2.2.

Regulatory Guide 1.96

Design of Main Steam Isolation Valve Leakage Control Systems for Boiling Water Reactor Nuclear Power Plants

Discussion

This regulatory guide is not applicable to the CPNPP.

Regulatory Guide 1.97

Instrumentation for Light-Water-Cooled Nuclear Power Plants to Assess Plant Conditions During and Following an Accident

Discussion

A plant specific analysis of the information system requirements for CPNPP was conducted. This analysis was based on the design basis accident event scenarios and required operator actions, using the guidance provided in U.S. NRC Regulatory Guide 1.97, Revision 2. As a result, specific variables were selected and specific design and qualification criteria developed to assure the safety of CPNPP. These variables and criteria are described in detail in Section 7.5.

Regulatory Guide 1.98

Assumptions Used for Evaluating the Potential Radiological Consequences of a Radioactive Offgas System Failure in a Boiling Water Reactor

Discussion

This regulatory guide is not applicable to the CPNPP.

Regulatory Guide 1.99

Effects of Residual Elements on Predicted Radiation Damage to Reactor Vessel Materials

Discussion

Refer to Appendix 1A(N).

Regulatory Guide 1.100

Seismic Qualification of Electric Equipment for Nuclear Power Plants

Discussion

The CPNPP design for Class 1E Electrical Equipment complies with the requirements and recommendations of Revision 1 (8/77) of this regulatory guide with the following clarification:

The intent of Section C.1 is met by performing an analysis to verify the approach and/or by following the Equivalent Static Load Method.

Also refer to Section 3.10B and Appendix 1A(N).

Regulatory Guide 1.101

Emergency Planning for Nuclear Power Plants

Discussion

Section 13.3 Appendix A, “Emergency Planning,” is intended to comply with the contents of Revision 3 (8/92) of this regulatory guide with the following exception:

Vistra OpCo takes exception to the part of Section C which states licensees may use either NUREG 0654/FEMA-REP-1 or NUMARC/NESP-007 in developing their EAL scheme but may not use portions of both methodologies. CPNPP EALs were developed and implemented in accordance with the guidance in the NRC-endorsed NEI 99-01 Rev. 6, "Development of Emergency Action Levels for Non-Passive Reactors.”

Regulatory Guide 1.102

Flood Protection for Nuclear Power Plants

Discussion

Plant grade for the CPNPP is located above the PMF level, and Category I structures, with the exception of the Service Water Intake Structure and the Electrical and Control Building, are not subject to flooding.

The operating deck and safety-related equipment in the Service Water Intake Structure are located above the PMF level. Flooding of the Electrical and Control Building is prevented by the use of incorporated barriers (i.e., isolation valves and/or stop-gates in the Circulating Water System). Emergency operating procedures are discussed in Section 3.4 and 13.5. Therefore the CPNPP is in conformance with Revision 1 (9/76) of this regulatory guide.

Also refer to Sections 2.4 and 3.4.

Regulatory Guide 1.103

Post-Tensioned Prestressing Systems for Concrete Reactor Vessels and Containments

Discussion

This regulatory guide is not applicable to the CPNPP.

Regulatory Guide 1.104

Overhead Crane Handling Systems for Nuclear Power Plants

Discussion

This regulatory guide was withdrawn August 16, 1979.

CPNPP cranes and hoists which are required to be single failure proof are described in “CPNPP Final Response to NUREG-0612”, dated June 1983. Updates to this response are made via DBD-ME-006 which is incorporated by reference (See Table 1.6-1). Also refer to sections 9.1.4.2 and 9.1.4.3.

Regulatory Guide 1.105

Instrument Setpoints

Discussion

The CPNPP design complies with the provisions of Revision 2 (2/86) of this regulatory guide. Setpoint securing devices do not have separate physical locks (requiring an administratively controlled key). The adjustment of setpoints and release/securing of securing devices is controlled by administrative procedures.

Also refer to Appendix 1A(N) and Section 7.1.

Regulatory Guide 1.106

Thermal Overload Protection for Electric Motors on Motor-Operated Valves

Discussion

The CPNPP design complies with the provisions of Revision 1 (3/77) of this regulatory guide as described in Section 8.3.1.1.11 Item 2.

Regulatory Guide 1.107

Qualifications for Cement Grouting for Prestressing Tendons in Containment Structures

Discussion

This regulatory guide is not applicable to the CPNPP.

Regulatory Guide 1.108

Periodic Testing of Diesel Generators Used As Onsite Electric Power Systems at Nuclear Power Plants

Discussion

The CPNPP design complies with the intent of Revision 1 (8/77) of this regulatory guide.

1. The requirements of position C. 1b.4 are satisfied as described below:

    a. Diesel generator (D-G) “Ready Stand by” status indication in the Control Room can be acknowledged by the combination of a green light for output breaker and the absence of a “D-G disable” and a “D-G trouble” annunciator indication.

b. "D-G Lockout" status is indicated by means of a "D-G disable" annunciation in the Control Room. This status is also indicated by "DG PWR" indication on the safety system bypass and inoperable status indicating light box in the Control Room due to any of the following:

1. DC power unavailable

2. Remote-Local-Maintenance switch not in remote on the generator control panel.

c. "D-G undertest" status light is not provided in the CPNPP design.

d. A means of communication is provided between the diesel generator room and the Control Room.

2. The requirements of Regulatory Positions are clarified as described below:

Regulatory Position C.2.a.(4)

The largest single load is taken to be the largest single end load and not combined distribution system loads (e.g., distribution system transformers or load centers). This load is 783 kW equal to the nameplate rating of the Component Cooling Water pump.

Regulatory Position C.2.d

If the number of failures in the last 100 valid tests is seven or more for an individual diesel generator unit, the reliability of that diesel generator requires special evaluation (i.e., the reliability of both diesel generators is not impacted).

3. The CPNPP periodic testing program meets the intent of the regulatory guide with the following exceptions:

a. Regulatory Position C.2.a.3

During preoperational testing, testing will be conducted at the full-load-carrying capability for an interval of not less than 24 hours, of which 22 hours will be at the continuous rating capability of the diesel generator and 2 hours at a load equivalent to the two hour rating of the diesel generator. At a frequency specified in accordance with Technical Specification 5.5.21, "Surveillance Frequency Control Program", testing will be conducted to demonstrate full-load-carrying capability for an interval of not less than 24 hours, of which 22 hours will be at a load which exceeds the maximum expected diesel generator load requirements and 2 hours at a load which is approximately 110% of this maximum expected load.

b. Regulatory Position C.2.a.5

Demonstrate functional capability at full load temperature conditions by rerunning the test phase outlined in Regulatory Position C.2.a.1 and by demonstrating proper operation for shutdown-loading-sequence to shutdown-load requirements

immediately following the performance of C.2.a.3, except during preoperational testing when the proper operation for the design-accident-loading-sequence to design-load requirements will be demonstrated.

c. Regulatory Position C.2.a.9

Demonstrate the reliability of the Emergency Diesel Generator by performing at least a total of 69 (but no less than 35 per Emergency Diesel Generator) consecutive valid start and load tests on the Emergency Diesel Generators from cold ambient conditions to at least 50 percent continuous rating for at least 1 hour with no failures. These tests need not be performed as part of the pre-operational test program, but may be performed at any time prior to the required operability of the Emergency Diesel Generator.

d. Regulatory Position C.2.c.2

Periodic testing of the diesel generator units during normal plant operation to demonstrate full-load-carrying capability will be conducted at a load which exceeds the maximum expected diesel generator load requirements. During this test, loading to the diesel generator is accomplished in accordance with vendor recommendations.

e. Regulatory Position C.2.d

Diesel generators testing frequency is in accordance with the requirements of the technical specifications.

4. The requirements of Regulatory Position c.3.b is satisfied as described below:

Other existing reporting requirements adequately ensure that the NRC learns of significant problems with diesel generator performance. Reporting requirements for EDG failures provided in this section will not be submitted.

Regulatory Guide 1.109

Calculation of Annual Doses to Man from Routine Releases of Reactor Effluents for the Purpose of Evaluating Compliance with 10 CFR Part 50, Appendix I

Discussion

Compliance with Appendix I was evaluated in accordance with Revision 1 (10/77) of this regulatory guide.

Also refer to Appendix 11A.

Regulatory Guide 1.110

Cost-Benefit Analysis for Radwaste Systems for Light-Water-Cooled Nuclear Power Reactors

Discussion

This regulatory guide is not applicable to the CPNPP.

Regulatory Guide 1.111

Methods for Estimating Atmospheric Transport and Dispersion of Gaseous Effluents in Routine Releases from Light-Water-Cooled Reactors

Discussion

The methods of Revision 1 (7/77) of this regulatory guide were used in the evaluation of gaseous effluents as described in Appendix 11A.

Regulatory Guide 1.112

Calculation of Releases of Radioactive Materials in Gaseous and Liquid Effluents from Light-Water-Cooled Power Reactors

Discussion

The radioactive source terms calculation presented in Section 11.1 complies with the requirements of Revision O-R (4/76 - reissued 5/77) of this regulatory guide.

Regulatory Guide 1.113

Estimating Aquatic Dispersion of Effluents from Accidental and Routine Reactor Releases for the Purpose of Implementing Appendix I

Discussion

The methods of Revision 1 (4/77) of this regulatory guide were used in the evaluation of effluents as described in Appendix 11A.

Regulatory Guide 1.114

Guidance on Being Operator at the Controls of a Nuclear Power Plant

Discussion

The CPNPP administrative operating procedures will incorporate the applicable guidance of Revision 1 (11/76) of this regulatory guide.

Also refer to Section 13.5.

Regulatory Guide 1.115

Protection Against Low Trajectory Turbine Missiles

Discussion

The turbines of the CPNPP are so oriented that low trajectory turbine missiles cannot strike any of the essential systems as discussed in Section 3.5. The CPNPP design is in compliance with Revision 1 (7/77) of this regulatory guide.

Regulatory Guide 1.116

Quality Assurance Requirements for Installation, Inspection, and Testing of Mechanical Equipment and Systems

Discussion

This regulatory guide is not applicable to CPNPP design and construction. The quality assurance methods for operations phase activities will comply with the applicable guidance contained in Revision 0-R (5/77) of this regulatory guide. Application of the requirements of ANSI N45.2.8 - 1975, as endorsed by this regulatory guide, will be in accordance with guidance contained in ANSI N18.7 - 1976.

Also refer to Section 17.2.

Regulatory Guide 1.117

Tornado Design Classification

Discussion

The CPNPP structures, systems, and components are designed to withstand the effects of a design basis tornado, including tornado missiles, in conformance with Revision 1 (4/78) of this regulatory guide.

Also refer to Section 3.5.

Regulatory Guide 1.118

Periodic Testing of Electric Power and Protection Systems

Discussion

Although the implementation of this regulatory guide, dated June 1976, does not include CPNPP, the CPNPP electrical power systems are testable to the extent described in FSAR Section 8.2.1.2.2, 8.3.1.1.11 item 3 and 8.3.2.1 item 6.

Regulatory Guide 1.119

Surveillance Program for New Fuel Assembly Designs

Discussion

This regulatory guide was withdrawn June 23, 1977.

Regulatory Guide 1.120

Fire Protection Guidelines for Nuclear Power Plants

Discussion

The fire protection system design for CPNPP is in accordance with the criteria outlines in Appendix A to Branch Technical Position APCSB 9.5-1, “Guidelines for Fire Protection for Nuclear Power Plants Docketed Prior to 7/1/76.” The fire protection system design complies with the requirements for plants under construction except as stated in Section 9.5.1 of the FSAR. Where the guidelines of Revision 1 (11/77) of Regulatory Guide 1.120 are comparable with those of BTP APCSB 9.5-1, the former criteria are employed to the extent practical for the CPNPP design.

The CPNPP Fire Protection Program is described in Section 9.5.1.6.1 and Appendix 13.3B.

Regulatory Guide 1.121

Bases for Plugging Degraded PWR Steam Generator Tubes

Discussion

Refer to Appendix 1A(N).

Regulatory Guide 1.122

Development of Floor Design Response Spectra for Seismic Design of Floor Supported Equipment or Components

Discussion

Floor Design Response Spectra are developed in accordance with the methods described in Revision 1 (2/78) of this regulatory guide with the following conservative clarification to C.2:

In constructing instructure response spectra, uncertainties inherent to the analysis, such as the material properties of the foundation material and the structures, damping values, soil structure interaction, approximations in modeling techniques and computation of structural natural frequencies, are accounted for by parametric variations incorporated into the analysis and by broadening the peaks of the resulting envelope response spectra.

The procedure of parametric variations consists of evaluating and using in the dynamic analysis lower bound, best estimate, and upper bound values for the foundation spring constants in the case of all seismic Category I structures with the exception of the Fuel Building and the Service Water Intake Structure, where only lower bound and upper bound values are used. In addition, the analysis of the Containment Building is performed for each set of foundation spring constants by considering a cracked and an uncracked containment wall. Then, before smoothing of the envelope spectra, which envelopes the spectra developed for each parametric variation, a minimum frequency shift to the peaks of + 10 percent is also incorporated to account for other variations in the structural properties which are not considered in the described parametric

variation approach. This approach is more conservative than applying a peak shifting to spectral curves generated from a single dynamic model, without considering parametric variation.

The Fuel Building was re-analyzed to determine the effects of added mass due to the addition of high density spent fuel storage racks. Best estimate soil properties were used in the re-rack analysis in lieu of parametric variations involving upper and lower bound soil properties. The resulting spectrum peak responses were widened by at least +/- 15% in accordance with RG 1.122. The results from this approach remain conservative since results of previous studies show that variations in soil properties and building structure stiffness have minimal effect on the dynamic response of the Fuel Building.

Also see Section 3.7B.2.5.

Regulatory Guide 1.123

Quality Assurance Requirements for Control of Procurement of Items and Services for Nuclear Power Plants

Discussion

The quality assurance program for design and construction at CPNPP incorporates the intended objectives of ANSI N45.2.13 (Draft dated 5/73). The quality assurance methods and administrative controls utilized in the procurement of quality-related items and services, during the operations phase, as described in Section 17.2, will be consistent with the applicable guidance contained in Revision 1 (7/77) of this regulatory guide. The application of the provisions of ANSI N45.2.13 - 1976, as endorsed by this regulatory guide, will be in accordance with the guidance provided in ANSI N18.7 - 1976 except for imposing quality assurance program requirements consistent with 10CFR50 Appendix B or ANSI N45.2 in procurement documents for commercial grade calibration services from a NVLAP or A2LA accredited calibration laboratory evaluated in accordance with Section 17.2.7.

Regulatory Guide 1.124

Design Limits and Loading Combinations for Class 1 Linear-Type Component Supports

Discussion

All non-NSSS supplied Class I linear-type supports comply with Revision 1 (1/78) of this regulatory guide, with the following exceptions:

1. Paragraph C.4 (which is also referenced in Paragraphs C.5 and C.7)

   Service limits for bolts shall be increased for Service Level D (faulted) plant conditions. The increased allowable permitted for tensile stress in bolts shall not exceed the lesser of 0.7 Su or Sy at temperature. The increased allowable permitted for shear stress in bolts shall not exceed the lesser of 0.42 Su or 0.6 Sy. This exception is implemented by the use of ASME III Subsection NF paragraphs NF-3225 and NF-3324.6 of the 1983 Edition - Summer 1983 Addenda for the design of bolting.

The current industry position on the design of bolting is that the maximum safe increased allowables are achieved by limiting bolting tensile stress to the lesser of 0.7 Su or Sy at temperature and bolting shear stress to 0.42 Su or 0.6 Sy at temperature. The 0.7 Su limit is well recognized in Section III of the Code. The average shear strength of bolting material is about 0.62 Su according to test data, with a standard deviation of 0.033. Results indicate that the ratio of sear strength to tensile strength is independent of the bolt grade. Curves showing this appear on page 50 of "Guide to Design for Bolted and Riveted Joints," by J. W. Fisher. Test data are given in a paper by J. J. Wallaert and J. W. Fisher, "Shear strength of High-Strength Bolts," Journal of the Structural Division, ASCE, Volume 91, ST3, June 1965.

2. Paragraph C.8 (which is also referenced in Paragraphs C.6 and C.7)

As stated in Appendix 1A(N) of Section 1.0, system functional capability is provided for in Class 1 piping systems by maintaining the pipe stresses within Level D (faulted) limits. This assures that piping geometry is maintained and that required flow is not impaired. The selection of more restrictive stress limits for component supports is not necessary to assure the functional capability of the system.

However, to provide additional conservatism, ASME Class 1 component supports associated with the Safety Injection System and the Containment Spray system are designed to the limits described in Regulatory Position C-6 for Level C (emergency) conditions when subjected to the loadings associated with the Level D (faulted) plant condition.

Also refer to Appendix 1A(N) for a discussion of NSSS-supplied Class 1 supports.

Regulatory Guide 1.125

Physical Models for Design and Operation of Hydraulic Structures and Systems for Nuclear Power Plants

Discussion

This regulatory guide is not applicable to CPNPP.

Regulatory Guide 1.126

An Acceptable Model and Related Statistical Methods for the Analysis of Fuel Densification

Discussion

Refer to Appendix 1A(N).

Regulatory Guide 1.127

Inspection of Water-Control Structures Associated with Nuclear Power Plants

Discussion

CPNPP commits to comply with the requirements of Revision 1 (3/78) of this regulatory guide for the Safe Shutdown Impoundment in the manner described in Chapters 2.4 and 2.5 of the FSAR. Additionally, inspections addressed in the guide relative to Embankment Slope Stability, Unlined Saddle Spillways, the Reservoir proper and the Intake Structure and Discharge Channel will be accomplished.

This guide is not applicable to Squaw Creek Dam which is not safety related.

Regulatory Guide 1.128

Installation Design and Installation of Large Lead Storage Batteries for Nuclear Power Plants

Discussion

This regulatory guide is not applicable to CPNPP.

Regulatory Guide 1.129

Maintenance, Testing, and Replacement of Large Lead Storage Batteries for Nuclear Power Plants

Discussion

The CPNPP design complies with the provisions of Revision 1 (2/78) of this regulatory guide, with the clarification that IEEE 450-1995 applies instead of IEEE 450-1975 as endorsed by the regulatory guide. Refer to Section 8.3 for further discussion.

Regulatory Guide 1.130

Service Limits and Loading Combinations for Class 1 Plate-and-Shell-Type Component Supports

Discussion

Refer to Appendix 1A(N).

Regulatory Guide 1.131

Qualification Tests of Electric Cables, Field Splices, and Connections for Light-Water-Cooled Nuclear Power Plants

Discussion

Although the implementation of this regulatory guide, dated August 1977, does not include CPNPP, all Class 1E cables and field splices of the CPNPP meet most of the requirements of this regulatory guide with the few exceptions noted below:

1. All prefabricated cables of the CPNPP do not meet the following requirements:

a. Vertical tray flame test on the aged cables to determine their relative self-extinguishing tendencies. (Regulatory Guide position C.6),

b. Flame testing with the gas burner face in the front (Regulatory Guide position C.10). However, work is in progress by vendor on these items.

2. All 8kv cables, 600V power and lighting cables of the CPNPP do not meet the following requirements:

a. "Radiation Exposure Total" - per Regulatory Guide 1.89 Position C.5.

b. Vertical tray flame test on the aged cables to determine their relative self-extinguishing tendencies. (Regulatory Guide position C.6).

c. Flame testing with the gas burner face in the front (Regulatory Guide position C.10).

d. Gas and air flow requirements (Regulatory Guide position C.11).

3. All Raychem type WCSF-N field splices of the CPNPP have not been tested according to the following regulatory guide positions:

a. Vertical tray flame test on aged cable splices to determine their relative self-extinguishing tendencies. (Regulatory Guide Position C.6).

b. Flame testing with only natural grade propane and a release of approximately 70,000 BTU per hour at an air-gas ratio of 5 to 1. (Regulatory Guide Position C.9).

c. Flame testing with the gas burner face in the front. (Regulatory Guide Position C.10).

d. Gas and air flow requirements. (Regulatory Guide Position C.11).

e. Flame temperature requirements. (Regulatory Guide Position C.13).

4. The Partial Discharge Monitor Bus Coupler jumpers (15 kV rated) installed in the motor and emergency diesel generator termination boxes are not flame retardant and are not qualified to the requirements of Regulatory Guide 1.131.

Regulatory Guide 1.132

Site Investigations for Foundations of Nuclear Plants

Discussion

This regulatory guide is not applicable to CPNPP.

Regulatory Guide 1.133

Loose-Part Detection Program for the Primary System of Light-Water-Cooled Reactors

Discussion

The CPNPP O.L. Application was docketed prior to June 1, 1978, as provided by this guide dated September 1977.

A discussion of the CPNPP loose parts monitoring system is provided in Section 4.4.6.4.

Regulatory Guide 1.134

Medical Evaluation of Nuclear Power Plant Personnel Requiring Operator Licenses

Discussion

The medical certification and monitoring requirements of licensed personnel comply with the requirements of Revision 2 (4/87) of this regulatory guide.

Regulatory Guide 1.135

Normal Water Level and Discharge at Nuclear Power Plants

Discussion

This regulatory guide is not applicable to CPNPP.

Regulatory Guide 1.136

Material for Concrete Containments

Discussion

This regulatory guide is not applicable to CPNPP; however, the application of ACI-359 is discussed in Section 3.8.1.2.1.

Regulatory Guide 1.137

Fuel-Oil Systems for Standby Diesel Generators

Discussion

The CPNPP design complies with the requirements of this regulatory guide, dated January 1978, with the following exception to portions of Parts C.1, C.1.b, C.1.d, C.1.g, C.2.b, C.2.c, C.2.d, and C.2.f:

1. Part C.1.b (Paragraph 7.1 of ANSI N195-1976 [49]):

Venting components for the storage and day tanks are not safety class 3. However, piping and components are seismically supported and missile protection requirements are satisfied for the vent path.

2. Part C.1.d (Paragraph 6.1 of ANSI N195-1876):

   The suction from the day tank is provided from the bottom of the tank.

3. Part C.1.g (Paragraph 7.5 of ANSI N195-1976):

   Fill lines to the storage and day tanks do not have strainers.

4. Part C.2.b:

   Prior to addition of new fuel into the storage tanks, the fuel is tested in accordance with tests specified in ASTM D975-1981 for:

   a. [a]API or Specific Gravity when tested in accordance with ASTM D1298-1980

   b. Kinematic viscosity

   c. Flash point

   d. Water and Sediment (Either a Clear and Bright Test, ASTM D4176-1982 or a water and sediment content of less than or equal to 0.05% volume when tested in accordance with ASTM D1796-1968)

   The remainder of the tests specified in Table-1 of ASTM D975-1981 will be completed within 31 days of the fuel addition and fuel oil will meet the requirements when tested in accordance with ASTM D975-1981 except that the analysis for sulphur may be performed in accordance with ASTM D1552-1979 [46], ASTM D2622-1982 [47], or ASTM D4294-2003.

5. Part C.2.c:

   New fuel sampling procedures for the fuel oil will be in accordance with ASTM D4057-1981, “Standard Practice for Manual Sampling of Petroleum and Petroleum Products”.

6. Part C.1 (Paragraph 6.3 of ANSI N195-1976):

   The strainers provided in the diesel fuel oil transfer system are not duplex strainers.

---

a. If new fuel oil does not meet the diesel generator manufacturer’s requirements for absolute specific gravity at 60/60^{o}F of $\geq$ 0.8299 or for API gravity at 60^{o}F of $\leq$ 39^{o}, it is acceptable to add new fuel oil to the storage tank(s) only if, after being added, the entire storage tank(s) will meet the manufacturer’s recommendations.

7. Part C.2.d:

   Accumulated condensate is checked for, and removed from storage tanks at least every 31 days.

8. C.1 (Section 4 of ANSI N195-1976):

   Section 4 of the standard includes requirements for security for the diesel-generator fuel-oil system. The requirements of this section are not considered applicable to the CPNPP Security Plan since this subject is addressed separately in more detail in other NRC documents. See Section 13.6 for a description of security requirements.

9. C.2.a

   If new fuel oil does not meet the diesel generator manufacturer's requirements for absolute specific gravity at 60/60^{o}F of $\geq$ 0.8299 or for API gravity at 60^{o}F of $\leq$ 39^{o}, it is acceptable to add new fuel oil to the storage tank(s) only if, after being added, the entire storage tank(s) will meet the manufacturer's recommendations.

10. C.2.f

    The 10-year requirement to drain the supply tank and remove accumulated sediment in order to perform the ASME Section XI, Article IWD-2000, "Examination Requirements" is not valid. The test from ASME Section XI, Article IWD-2000 was a pressure test of the tank. The tanks are and have been vented to atmosphere. CPNPP has been draining and cleaning the tanks to perform ultrasonic wall thickness testing in lieu of the pressure test. Based on the following factors Emergency Diesel Generator (EDG) fuel oil storage tank testing is performed in accordance with the Preventative Maintenance Program:

    a. Results of prior tank cleaning and ultrasonic testing

    b. Fuel Oil Storage Tank (FOST) exterior coating

    c. Quality of FOST backfill material

    d. Cathodic protection of the FOST and associated piping

    e. All new fuel oil is sampled prior to admittance into the FOST in accordance with the Diesel Fuel Oil Testing Program

    f. FOST levels are recorded every 24 hours and after running the associated EDG

    g. FOST level is maintained greater than 88,000 gallons per daily logs with a Technical Specification minimum of 86,000 gallons

    h. TSTF-2-A, Revision 1, Relocate the 10 year sediment cleaning of the fuel oil storage tank to licensee control

Also refer to Section 9.5.4.

Regulatory Guide 1.138

Laboratory Investigations for Soils for Engineering Analysis and Design Of Nuclear Power Plants

Discussion

This regulatory guide is not applicable to CPNPP; however, soils investigations are discussed in Section 2.5.

Regulatory Guide 1.139

Guidance for Residual Heat Removal

Discussion

Refer to Appendix 1A(N).

Regulatory Guide 1.140

Design, Testing and Maintenance Criteria for Normal Ventilation Exhaust System Air Filtration and Absorption Units of Light-Water-Cooled Nuclear Power Plants

Discussion

The CPNPP design, maintenance and testing of the normal HVAC systems is in compliance with the requirements of Regulatory Guide 1.140 (03/78) except part C.3.h, water drains; part C.4.b, ease of maintenance; part C.4.c, test probes;, part C.5.b, air flow distribution; parts C.5.c and C.5.d, in-place testing; and part C.6, laboratory testing criteria for activated carbon.

1. Part C.3.h, Water drains:

   Check valves have been used on some drains in lieu of seals or traps. The drains for the demister compartments of the Hydrogen Purge Filtration units have not been provided with seals, traps, or check valves. Any minimal airflow through the demister drain will be filtered prior to discharge at the stack. This design conforms to the intent of NRC Regulatory Guide 1.140 (03/78).

2. Part C.4.b, Ease of Maintenance:

   The spacing provided between the components of the filtration units is, in some cases, less than the minimum required by this regulatory position. However, it has been determined by operation and maintenance personnel that the spacing provided is sufficient to perform all the required maintenance operations. This design conforms to the intent of Regulatory Guide 1.140 (03/78).

3. Part C.4.c, Test Probes:

   Test ports will be provided in lieu of permanently installed test probes. Permanently installed probes are a convenience in the periodic testing of filters and adsorbers.

Replacing them with test ports is of no safety significance. This design meets the intent of NRC Regulatory Guide 1.140 (03/78).

4. Part C.5.b, Air Flow Distribution:

The air flow distribution to the HEPA filters and iodine adsorbers will be tested in place for uniformity initially and after maintenance affecting the flow distribution for all units except the hydrogen purge units.

5. Parts C.5.c and C.5.d, In-Place Testing Criteria

ANSI/ASME N509-1980 and ANSI/ASME N510-1980 shall be used for field testing activities in place of the older versions of these codes referenced in this regulatory guide.

Atmospheric cleanup trains installed at CPNPP have two HEPA filter banks in series with a charcoal adsorber between them. In-place testing of the upstream HEPA bank only will be performed.

In-place testing of the HEPA filter banks and adsorber will not be required following painting, fire and chemical release described in position C.5.c and C.5.d of this guide. Only laboratory testing will be performed for carbon efficiencies. This design conforms to the intent of NRC Regulatory Guide 1.140 (03/78).

HEPA filter and charcoal adsorber efficiency for non-Engineered Safety Feature Filtration Units is 90% which corresponds to an acceptance criteria of less than 1% for in-place penetration and bypass leakage at rated flow.

The in-place testing of the HEPA filter and charcoal adsorber for the containment preaccess filtration units is performed in accordance with ANSI N510-1980, Table 1, NOTES 2 & 5. As discussed in FSAR section 9.4A, the preaccess filtration system is a recirculating system inside containment that reduces airborne contamination inside containment prior to personnel entry. Leakage through the HEPA or charcoal adsorber would not contribute to any increased radiological release to the environment. This design conforms to the intent of Reg. Guide 1.140 (3/78).

6. Part C.6, Laboratory Testing Criteria for Activated Carbon:

Laboratory testing of activated carbon will be in accordance with ANSI N509 and N510-1980 (which refers to ASTM D3803-79), except for the determination of the efficiency of charcoal to remove radioiodine. The parameters applicable to new and used charcoal at CPNPP shall be applied in the lab test as follows:

<u>New and Used Charcoal</u>
4" Beds
40 ft/min
30°C & 95% RH
Pre-equilibrated

The allowable methyl iodide penetration for these units shall be 10% as shown in Table 2 of the Regulatory Guide.

When all or most of the charcoal canisters in the filtration units have been used, a representative sample of the charcoal from the bed will be obtained by grain thief sampling in accordance with ANSI N509-1980, Appendix A. The representative samples obtained with the grain thief will be used for laboratory testing and/or refilling the charcoal canisters.

The carbon adsorber beds will be replaced when (1) testing in accordance with the frequency specified in Footnote c of Table 2 results in a representative sample failing to pass the applicable test in Table 2 or (2) no representative sample is available for testing, at a time when testing is required.

This design conforms to the intent of NRC Regulatory Guide 1.140 (03/78).

Regulatory Guide 1.141

Containment Isolation Provisions for Fluid Systems

Discussion

This regulatory guide is not applicable to CPNPP; however, the containment isolation is discussed in Section 6.2.

Regulatory Guide 1.142

Safety-Related Concrete Structures for Nuclear Power Plants (Other Than Reactor Vessels and Containments)

Discussion

This regulatory guide is not applicable to CPNPP; however the design of safety-related concrete structures is discussed in Section 3.8.

Regulatory Guide 1.143

Design Guidance for Radioactive Waste Management Systems, Structures, and Components Installed in Light-Water-Cooled Nuclear Power Plants

Discussion

This regulatory guide is not applicable to CPNPP, however, the code, code class, safety class, and seismic classification of Liquid Waste Processing and Gaseous Waste Processing System components comply with Table 1 of Regulatory Guide 1.143, Rev. 1. Reference Section 11.2, 11.3 and 11.4 for related information.

Regulatory Guide 1.144

Auditing of Quality Assurance Programs for Nuclear Power Plants

Discussion

The program for auditing of Quality Assurance Programs for CPNPP complies with the requirements of Regulatory Guide 1.144 Revision 1 (9/80). The following suppliers are not audited by Vistra OpCo and are exempt from the requirements of this regulatory guide:

National or state calibration sources

Authorized Nuclear Inspection Agency

NVLAP and A2LA accredited commercial grade calibration suppliers evaluated in accordance with Section 17.2.7.

For triennial supplier audits (Section 17.2.7), the audit schedule shall be based on the month in which the audit starts. An interval extension grace period of up to 25% may be used for the scheduled commencement date when conditions, such as plant operational considerations or to accommodate supplier activities, make meeting the specified schedule date impractical. When an audit interval extension greater that one month is used, the next audit will be scheduled from the original anniversary month rather than from the month of the extended audit. The total combined time interval for any three consecutive audit intervals should not exceed 3.25 times the specified audit interval.

Regulatory Guide 1.145

Atmospheric Dispersion Models for Potential Accident Consequence Assessments at Nuclear Power Plants

Discussion

This regulatory guide is not applicable to CPNPP.

Regulatory Guide 1.146

Qualification of Quality Assurance Program Audit Personnel for Nuclear Power Plant

Discussion

Effective June 1, 1983, CPNPP Quality Assurance Audit Personnel are in compliance with regulatory guide 1.146, August 1980.

Regulatory Guide 1.148

Functional Specification for Active Valve Assemblies in Systems Important to Safety in Nuclear Power Plants

Discussion

CPNPP is not committed to this Regulatory Guide. The operability program for active valves is covered in Section 3.9N and 3.9B.

Regulatory Guide 1.150

Ultrasonic Testing of Reactor Vessel Welds During Preservice and Inservice Examinations.

Discussion

Refer to Appendix 1A(N).

Regulatory Guide 1.155

Station Blackout

Discussion

CPNPP complies with the guidance of Regulatory Guide 1.155 (August 1988) as described in Appendix 8B.

Regulatory Guide 1.163

Performance-Based Containment Leak-Test Program

Discussion

Effective by August 12, 1996, CPNPP complies with Regulatory Guide 1.163, September 1995.

Regulatory Guide 1.195

Methods and Assumptions for Evaluating Radiological Consequences of Design Basis Accidents at Light-Water Nuclear Power Reactors, May 2003.

Discussion

The radiological consequences analysis for the design basis accidents follow the guidance provided in Regulatory Guide 1.195 and CPNPP adopts the dose limits defined by Regulatory Guide 1.195. The CPNPP design for skin dose calculations DCFs uses DOE/EH-0070 instead of Figure 12 recommended in Regulatory Guide 1.195.

Regulatory Guide 1.196

Control Room Habitability at Light-Water Nuclear Power Reactors, May 2003.

Discussion

The Control Room Envelope Habitability Program in Technical Specification 5.5.20 is consistent with the guidance of TSTF-448, Revision 3, which incorporate the specific aspects of Regulatory Guides 1.196 and 1.197. CPNPP currently uses RG 1.52, Revision 1 for the control room design. CPNPP used Revision 2 for testing only. CPNPP uses RG 1.140 as information only for non-safety related air filtration systems.

Regulatory Guide 1.197

Demonstrating Control Room Envelope Integrity at Nuclear Power Reactors, May 2003.

Discussion

The Control Room Envelope Habitability Program in Technical Specification 5.5.20 is consistent with the guidance of TSTF-448, Revision 3, which incorporates the specific aspects of Regulatory Guide 1.197 with the following exceptions:

1. C. - Section 4.3.2 “Periodic CRH Assessment” from NEI 99-03 Revision 1 will be used as input to a site specificSelf assessment procedure.

2. C.1.2 - No peer reviews are required to be performed.

Regulatory Guide 8.10

Operating Philosophy for Maintaining Occupational Radiation Exposures as Low as Reasonably Achievable, May 1977.

Discussion

The administration of the As Low As Reasonably Achievable (ALARA) Program at CPNPP will be in accordance with Regulatory Guide 8.10 with the following exception:

1. The radiation workers at CPNPP will be tested at the frequency of 24 months nominal not to exceed 27 months for supplemental workers and 48 months not to exceed 51 months for utility workers. These frequencies are set as quarterly basis.

2.0 SITE CHARACTERISTICS

LIST OF TABLES

Number	Title
2.1-1	HISTORICAL AND PROJECTED POPULATIONS FOR COUNTIES WITHIN 50 MILES OF CPNPP
2.1-2	CENTERS OF POPULATION WITHIN 50 MILES OF CPNPP
2.1-3	POPULATION DISTRIBUTION BY SECTOR-AREA WITHIN 10 MILES OF CPNPP
2.1-4	POPULATION DISTRIBUTION BY AGE GROUPS WITHIN 10 MILE RADIUS OF CPNPP FOR YEAR 2000
2.1-5	POPULATION DISTRIBUTION BY SECTOR-AREA WITHIN 10 MILES OF CPNPP
2.1-6	POPULATION DISTRIBUTION BY AGE GROUPS BETWEEN 10 AND 50 MILE RADIUS OF CPNPP FOR YEAR 2000
2.1-7	TYPE AND TYPICAL LENGTH OF STAY OF TRANSIENTS WITHIN 10 MILE RADIUS OF CPNPP
2.1-8	TRANSIENT POPULATION PROJECTIONS
2.1-9	MAXIMUM PERMANENT AND TRANSIENT POPULATION DISTRIBUTION BY SECTOR-AREA
2.2-1	NATURAL GAS PIPELINE INFORMATION
2.2-2	WEST TEXAS GULF CRUDE OIL LINE
2.3-1	TORNADO POINT PROBABILITY WITHIN A GIVEN YEAR AT SELECTED LOCATIONS (1955-1967)
2.3-2	AVERAGE NUMBER OF THUNDERSTORM DAYS AND LARGE-HAIL DAYS
2.3-2A	SEASONAL AND ANNUAL ESTIMATES OF LIGHTNING STRIKES TO SAFETY-RELATED STRUCTURES
2.3-3	MEAN SEASONAL AND ANNUAL MIXING DEPTHS AND WIND SPEEDS AT TEXAS STATIONS NEAREST THE REGION (1960-1964)
2.3-4	ESTIMATED RAINFALL (INCHES) FOR THE SITE AREA
2.3-5	MAXIMUM RECORDED POINT RAINFALL FOR SELECTED STATIONS IN THE REGION

LIST OF TABLES (Continued)

Number	Title
2.3-6	EXTREME SNOWFALLS AT SELECTED STATIONS IN THE REGION
2.3-7	DELETED
2.3-7A	ONSITE METEOROLOGICAL DATA
2.3-7B	OFFSITE METEOROLOGICAL DATA USED IN ULTIMATE HEAT SINK WATER SUPPLY PERFORMANCE EVALUATION
2.3-7C	OFFSITE METEOROLOGICAL DATA USED IN ULTIMATE HEAT SINK WATER SUPPLY PERFORMANCE EVALUATION
2.3-8	DELETED
2.3-9	DELETED
2.3-10	DELETED
2.3-11	PERCENT FREQUENCY DISTRIBUTION OF WIND AT LOVE FIELD (1951-1960)
2.3-12	MONTHLY VARIATION OF EXTREME “FASTEST MILE” WINDS FOR FORT WORTH AND DALLAS
2.3-13	WIND DIRECTION PERSISTENCE AT FORT WORTH (1969-1973)
2.3-14	WIND DIRECTION PERSISTENCE AT CPNPP
2.3-15	VALUES OF MEAN, AVERAGE AND EXTREME DAILY MAXIMUM, AND AVERAGE AND EXTREME DAILY MINIMUM SURFACE TEMPERATURES (°F) AT FORT WORTH (1931 - 1960)
2.3-16	STATISTICS AND DIURNAL VARIATION OF METEROLOGICAL PARAMETERS
2.3-17	MONTHLY AVERAGE RELATIVE HUMIDITY (PERCENT) AT FORT WORTH (1964-1973)
2.3-18	MONTHLY AND ANNUAL MEAN, AND EXTREME MAXIMUM AND MINIMUM DEWPOINT TEMPERATURES (°F) AT FORT WORTH (1970-1975)
2.3-19	MONTHLY AND ANNUAL AVERAGE VALUES IN THE SITE AREA
2.3-20	MONTHLY PRECIPITATION EXTREMES (Inches) AT SELECTED STATIONS

LIST OF TABLES (Continued)

Number	Title
2.3-21	PRECIPITATION WIND ROSE FORT WORTH, TEXAS
2.3-22	MONTHLY AND ANNUAL STABILITY CLASS PERCENT FREQUENCY DISTRIBUTIONS AT FORT WORTH (1957-1971)
2.3-23	STABILITY-PERSISTENCE AND DIURNAL DISTRIBUTION AT CPNPP (BASED ON 10-60 METER DELTA TEMPERATURE)
2.3-24	MEAN MONTHLY MIXING DEPTHS FORT WORTH (May 1972-April 1976)
2.3-25	COMPARISON OF 4- AND 15-YEAR WIND AND STABILITY CONDITIONS AT FORT WORTH
2.3-26	METEOROLOGICAL INSTRUMENTATION COMANCHE PEAK PREOPERATIONAL METEOROLOGICAL PROGRAM
2.3-27	WIND FREQUENCY DISTRIBUTIONS AT CPNPP
2.3-28	MINIMUM DISTANCE FROM THE REACTOR CONTAINMENT STRUCTURE TO THE EXCLUSION-AREA BOUNDARY
2.3-29	DELETED
2.3-30	DELETED
2.3-31	DELETED
2.3-32	DELETED
2.3-33	AVERAGE ANNUAL RELATIVE CONCENTRATION AT CPNPP (SEC./CUBIC METER) PERIOD OF RECORD: 5-15-72 TO 5-14-76

2.3-34A	METEOROLOGICAL INSTRUMENTATION COMANCHE PEAK OPERATIONAL METEOROLOGICAL PROGRAM OVERALL SYSTEM ACCURACIES
2.3-34B	METEOROLOGICAL INSTRUMENTATION COMANCHE PEAK OPERATIONAL METEOROLOGICAL PROGRAM DELTA TEMPERATURE SYSTEM ACCURACY
2.3-35	COMPARISON OF ANALOG AND DIGITAL DATA
2.3-36	DELETED

LIST OF TABLES (Continued)

Number	Title
2.3-37	5-PERCENTILE VALUES OF THE ACCIDENT PERIOD DIFFUSION ESTIMATES AT THE LPZ
2.3-38	50-PERCENTILE VALUES OF THE ACCIDENT PERIOD DIFFUSION ESTIMATES AT THE LPZ
2.4-1	PRINCIPAL DAMS AND RESERVOIRS UPSTREAM OF COX BEND
2.4-2	PRINCIPAL DAMS AND RESERVOIRS DOWNSTREAM OF COX BEND
2.4-3	POSSIBLE FUTURE RESERVOIRS ON BRAZOS RIVER BETWEEN POSSUM KINGDOM RESERVOIR AND LAKE WHITNEY
2.4-4	SURFACE WATER CLAIMS FILED (IRRIGATIONAL) - SQUAW CREEK
2.4-5	MUNICIPAL, INDUSTRIAL, MINING AND HYDROELECTRIC WATER USERS ON THE BRAZOS RIVER
2.4-6	IRRIGATIONAL WATER USAGE FROM BRAZOS RIVER BY COUNTY
2.4-7	ANNUAL FLOODS AT BRAZOS RIVER GAGING STATION 8-0910 (NEAR GLEN ROSE)
2.4-8	ANNUAL FLOODS AT GAGING STATION 8-0917 ON PANTER BRANCH OF SQUAW CREEK
2.4-9	ANNUAL FLOODS AT GAGING STATION 08091750 ON SQUAW CREEK NEAR GLEN ROSE
2.4-10	ANNUAL FLOODS AT GAGING STATION 8-0915 ON PALUXY RIVER NEAR GLEN ROSE
2.4-11	SQUAW CREEK RESERVOIR PROBABLE MAXIMUM FLOOD
2.4-12	COMPARISON OF PROBABLE MAXIMUM PRECIPITATION MAXIMUM RECORDED RAINFALL AND MAXIMUM RAINFALL LIKELY TO OCCUR AT SELECTED GAGING STATIONS NEAR CPNPP
2.4-13	UNIT HYDROGRAPH CHARACTERISTICS
2.4-14	COINCIDENT WIND WAVE ACTIVITIES
2.4-15	SAFE SHUTDOWN IMPOUNDMENT PROBABLE MAXIMUM FLOOD

LIST OF TABLES (Continued)

Number	Title
2.4-16	UNIT HYDROGRAPH CHARACTERISTICS FOR THE PANTHER BRANCH WATERSHED ABOVE THE SAFE SHUTDOWN IMPOUNDMENT
2.4-17	SQUAW CREEK RESERVOIR AREA AND CAPACITY CHARACTERISTICS
2.4-18	SAFE SHUTDOWN IMPOUNDMENT AREA AND CAPACITY CHARACTERISTICS
2.4-19	PREDICTED AREA AND CAPACITY CHARACTERISTICS OF THE SAFE SHUTDOWN IMPOUNDMENT AFTER FORTY YEARS OF SEDIMENTATION
2.4-20	CONCENTRATIONS OF RADIONUCLIDES IN POSTULATED ACCIDENTAL RELEASE
2.4-20A	CONCENTRATIONS OF RADIONUCLIDES IN POSTULATED ACCIDENTAL RELEASE
2.4-21	MAXIMUM CONCENTRATIONS IN SURFACE WATER DUE TO POSTULATED RELEASES FROM THE LIQUID RADIOACTIVE WASTE STORAGE TANK
2.4-22	GROUNDWATER CHEMICAL ANALYSES
2.4-23	ESTIMATED WATER USAGE AT CPNPP
2.4-24	PUBLIC SUPPLY, INDUSTRIAL AND IRRIGATION WELLS, 0-20 MILES
2.4-25	LOCAL WATER WELLS
2.4-26	SUMMARY OF PUMPAGE DURING CONSTRUCTION IN 1975
2.4-27	HISTORICAL GROUNDWATER LEVELS AROUND THE PLANT SITE
2.4-28	MAXIMUM DEPTH OF SIGNIFICANT CONCENTRATIONS OF RADIONUCLIDES IN THE GLEN ROSE LIMESTONE DUE TO POSTULATED ACCIDENTAL RELEASES
2.4-29	CONCENTRATIONS (Ci/ft^3) OF Cs-137 IN THE GLEN ROSE LIMESTONE DUE TO POSTULATED ACCIDENTAL RELEASES
2.5.1-1	TABULATION OF PRINCIPAL FAULTS - TEXAS
2.5.1-2	TABULATION OF PRINCIPAL FAULTS - TEXAS
2.5.1-3	TABULATION OF PRINCIPAL FAULTS - OKLAHOMA, ARKANSAS, LOUISIANA

LIST OF TABLES (Continued)

Number	Title
2.5.1-4	TABULATION OF PRINCIPAL FAULTS - OKLAHOMA, ARKANSAS, LOUISIANA
2.5.1-5	WELL DATA ON ALL WELLS WITHIN FIVE-MILE RADIUS OF COMANCHE PEAK S.E.S AS OF DECEMBER 31, 1980
2.5.1-6	RESERVOIR DATA SUMMARY
2.5.1-7	STATISTICAL SUMMARY OF RESERVOIR PROPERTIES
2.5.1-8	ABSOLUTE OPEN FLOW POTENTIAL CALCULATIONS
2.5.1-9	RESERVOIR DATA ON SELECTED WELLS WITHIN FIVE-MILE RADIUS OF CPNPP
2.5.1-10	GAS IN-PLACE ASSOCIATED WITH HYPOTHETICAL WELL
2.5.1-11	SURVEY OF REPORTED BOTTOM-HOLE PRESSURE IN HOOD AND SOMERVELL COUNTIES, TEXAS
2.5.2-1	MODIFIED MERCALLI INTENSITY SCALE OF 1931 (Abridged)
2.5.2-2	REGIONAL EARTHQUAKES
2.5.2-3	EARTHQUAKE ATTENUATION
2.5.4-1	SUMMARY OF UNCONFINED COMPRESSION TESTS
2.5.4-2	SUMMARY OF DOUBLE RING SHEAR TESTS
2.5.4-3	SUMMARY OF BRAZIL TENSILE TESTS
2.5.4-4	STATIC ROCK PROPERTIES
2.5.4-5	INITIALLY SELECTED VALUES OF PREEXCAVATION-DYNAMIC FOUNDATION DESIGN PARAMETERS
2.5.4-5A	DETAILS OF PREEXCAVATION CROSSHOLE SURVEYS
2.5.4-5B	REPRESENTATIVE GEOPHYSICAL DATA FROM PREEXCAVATION SURVEYS AT STTION LOCATION
2.5.4-5C	REPRESENTATIVE GEOPHYSICAL DATA FROM SAFE SHUTDOWN IMPOUNDMENT DAM LOCATION
2.5.4-5D	AMBIENT GROUND MOTION MEASUREMENTS

LIST OF TABLES (Continued)

Number	Title
2.5.4-5E	LITHO-STRATIGRAPHY OF SUBSURFACE MATERIALS TO A DEPTH OF 500 FT
2.5.4-5F	SUMMARY OF THE RESULTS OF THE POSTCONSTRUCTION CROSSHOLE SURVEY
2.5.4-5G	DYNAMIC ROCK PROPERTIES DETERMINED BY LABORATORY TESTING OF CORE SAMPLES
2.5.4-5H	DYNAMIC FOUNDATION DESIGN PARAMETERS BASED ON PREEXCAVATION AND POSTCONSTRUCTION GEOPHYSICAL SURVEYS
2.5.4-6	SUMMARY OF STATIC BEARING CAPACITY ANALYSIS OF CATEGORY I STRUCTURES
2.5.4-6A	SUMMARY OF DYNAMIC BEARING CAPACITY ANALYSIS OF CATEGORY I STRUCTURES
2.5.4-7	SUMMARY OF SETTLEMENT ANALYSIS FOR CATEGORY I STRUCTURES

2.1 GEOGRAPHY AND DEMOGRAPHY

2.1.1 SITE LOCATION AND DESCRIPTION

2.1.1.1 Specification of Location

The CPNPP site is located in Somervell County in North Central Texas. Squaw Creek Reservoir (SCR), established for station cooling, extends northward into Hood County. The site is owned by the Applicants. The site is situated along Squaw Creek, a tributary of the Paluxy River, which is a tributary of the Brazos River. The station site is over 30 miles southwest of the nearest portion of Fort Worth and approximately 4.5 miles north- northwest of Glen Rose, the nearest community (see Figure 2.1-1). Site coordinates are:

	Unit No. 1	Unit No. 2
Texas Grid (Feet)	Y = 229,723.96 X = 1,911,921.11	Y = 230,010.86 X = 1,911,951.27
U.T.M. Grid (Zone 14) (Meters)	N = 3,573,903 E = 614,393	N = 3,537,991 E = 614,401
Latitude	32º 17' 52.02"	32º 17' 54.85"
Longitude	97º 47' 06.15"	97º 47' 05.79"

2.1.1.2 Site Area

The site area map (Figure 2.1-2) shows the concurrent plant property and site boundary line, the Exclusion Area, and Squaw Creek Reservoir (SCR). The site area is approximately 7,700 acres. Site area access is by a plant railroad, which connects to the Atchison, Topeka and Santa Fe Railroad Company main line at Tolar, Texas, by a plant access road which connects to FM 56 (previously Highway 201) and by County road 213 (also known as Coates Rd) which connects to State Highway 144.

The plant railroad and access road are owned and controlled by the Applicants. There are no other highways, railways or navigable waterways which traverse or are immediately adjacent to the site. Vistra OpCo maintains Squaw Creek Park and controls access to the park and reservoir.

Principal plant structures are also shown on Figure 2.1-2.

2.1.1.3 Boundaries For Establishing Effluent Release Limits

The Exclusion Area consists of approximately 4,170 acres. Figure 2.1-2 depicts the Exclusion Area boundary. This boundary is used for establishing effluent release limits and enables the owners to fulfill their obligations with respect to the requirements of 10 CFR Parts 20 and 100 (see Section 2.1.2.1.5).

Figure 2.1-2 shows that the points of release for each of the two units are located closer to the southwest property line than any other segment of the property line. This southwesterly distance

coincides with the minimum Exclusion Area boundary distance, which is 5,067 feet (1544 meters) from the midpoint of the centerline between the Containment buildings.

2.1.2 EXCLUSION AREA AUTHORITY AND CONTROL

2.1.2.1 Authority

2.1.2.1.1 Surface Rights

CP PowerCo has acquired and will maintain surface ownership of all the land within the Exclusion Area (see Figure 2.1-2A). Accordingly, CP PowerCo has the authority to determine all activities within the Exclusion Area, except for certain improbable and de minimus mineral exploration activities as discussed in greater detail below.

That portion of Squaw Creek Reservoir which is within the Exclusion Area is subject to the waterway exclusion provided in 10 CFR Part 100.3(a). Consistent with that regulation, appropriate and effective arrangements will be made to control traffic on the reservoir to protect the public health and safety in case of emergency. The Exclusion Area is not traversed by any public highway or railroad. See Figure 2.1-2. The nearest primary public road, FM 56 (previously State Highway 201 as denoted on Figure 2.1-2), lies outside the Exclusion Area approximately 8900 feet southwest of the center line between the Containment buildings. CP PowerCo owns and operates the plant railroad from the plant to its junction with the Atchison, Topeka and Santa Fe Railroad at Tolar, Texas, approximately 11 miles from the site.

2.1.2.1.2 Mineral Rights

CP PowerCo has acquired mineral rights beneath all seismic Category I structures (see Figure 2.1-2C). Portions of the remainder of the Exclusion Area are subject to certain outstanding mineral rights. As noted above, CP PowerCo owns the surface rights for the entire Exclusion Area.

As to the mineral rights within the Exclusion Area not owned by CP PowerCo, CP PowerCo will assure that the exercise of such mineral rights will pose no health and safety threat during normal reactor operation or in the event of an accident. The only outstanding mineral rights in the Exclusion Area for CPNPP, and surrounding areas, relate to the exploration for and production of oil, gas, and other subsurface minerals. There are no outstanding rights which permit the production of surface minerals. As discussed in Section 2.5.1, the potential for commercial production of minerals at CPNPP and in the surrounding area is low. Thus, it is anticipated that the exercise of such outstanding mineral rights would involve only sporadic, exploratory activity, and little or no production.

Nevertheless, CP PowerCo will maintain sufficient authority and control over, and knowledge of, attempted ingress into the Exclusion Area to ensure that no unauthorized entry is allowed by use of a mobile patrol at random intervals. Ingress for the purpose of exercising mineral rights in any area within 2250 feet of a seismic Category I building (See Section 2.2.3.2.1) or within 2800 feet of either Containment Building (See Section 2.1.2.1.5) is prohibited by virtue of CP PowerCo ownership of the mineral rights or by deed restrictions on any reserved mineral rights. This area has been designated in Figure 2.1-2C as the “External Hazard Free Zone.” The distances of 2250 and 2800 feet are based upon the analysis of a postulated gas well in Section 2.2.3. The distance of 2250 feet from any seismic Category I building assures that any conceivable

detonation (of the maximum quantity of explosives that could be used within the exclusion area) would have no effect on the safety-related structures and components (see Regulatory Guide 1.91). The forbidden zone of 2800 feet in radius corresponds to the equivalent distance for the 2 hour dose limit of 10 CFR 100 and the maximum design basis accidents for CPNPP (See Section 15.6). Ingress to the remaining outer areas of the Exclusion Area will only be permitted pursuant to written agreements between CP PowerCo and the necessary parties which would provide that CP PowerCo has absolute authority to determine all activities within the Exclusion Area, including removal of personnel and equipment.

A mineral owner or lessee has no legal right to use physical force or to create a public disturbance to obtain access to the outer areas of the Exclusion Area for purposes of mineral exploration or extraction. If such access is sought as to areas outside the "External Hazard Free Zone", CP PowerCo likewise will refuse to allow access unless the written agreement discussed above has been executed by the mineral owner or lessee. In such case, legal remedy of a mineral owner or lessee to obtain access to the surface of the Exclusion Area after being so excluded would be to file a lawsuit in the State District Court for the county where the land is located (either Somervell or Hood County). Should such a suit be filed, CP PowerCo would then file an immediate cross-action to condemn the mineral rights of the party seeking ingress and thereby prevent the ingress. CP PowerCo has statutory authority to do so. Article 3269, V.A.T.S.

In this manner, CP PowerCo will have absolute authority to determine all activities within the Exclusion Area, including the authority to exclude or remove persons. Thus, the exercise of mineral rights in the Exclusion Area will pose no health and safety threat during normal reactor operation or in the event of an accident. In view of the unusual nature and limited scope of activities associated with the mineral rights and the plan and commitments by CP PowerCo to control all activities within the Exclusion Area, the present status of ownership is deemed to be of de minimis safety consequence.

As stated above, CP PowerCo has acquired the mineral rights beneath all seismic Category I structures as well as beneath the Squaw Creek Dam (See Figure 2.1-2C). No measurable subsidence due to mineral extraction is anticipated. See Section 2.5.1.2.6 for a discussion of the effects of mineral extraction in the area of the site.

2.1.2.1.3 Easements

A 6-inch natural gas pipeline and a 26-inch crude oil pipeline traverse the Exclusion Area about 4,900 feet southwest of the midpoint of the centerline between the Containment buildings as shown on Figure 2.1-2B. These pipelines are also described in Section 2.2.3. CP PowerCo has granted the pipeline owners easements which retain for CP PowerCo absolute control to determine all such activities within the Exclusion Area including ingress and egress for the purpose of maintaining the pipelines and their right-of-way.

2.1.2.1.4 Status of Ownership

CP PowerCo has acquired all of the land which will constitute the site property. One small tract of land within the site area has been excluded from purchase: the Hopewell cemetary east of the plant (see Figure 2.1-2). This tract is outside the Exclusion Area and is fenced off from the site property.

2.1.2.1.5 Minimum Exclusion Area Distance

The minimum distance to the Exclusion Area boundary from the midpoint of the centerline between the Containment buildings is 5,067 feet (1,544 meters) to the west-southwest. The minimum Exclusion Area boundary distance is substantially larger, and therefore more conservative, than the distance which literal compliance with 10 CFR 100 would dictate (See Section 15.6).

2.1.2.2 Control of Activities Unrelated to Plant Operation

Activities unrelated to plant operation which may be permitted within the Exclusion Area include the exercising of mineral rights and the maintenance of pipelines as described in Sections 2.1.2.1.2 and 2.1.2.1.3 above, and cattle grazing. Vistra OpCo will have the necessary control to determine these activities and will require that all persons involved in them report to the Plant Manager (See Section 13.1.1.2.1) or a designated representative prior to engaging in the activities.

Arrangements have been made (in coordination with the appropriate agencies) to control access to, activities on, and the removal of persons and property from the CPNPP owner controlled area in case of emergency. Arrangements for recreational use and emergency procedures governing such use have been completed. Vistra OpCo has the authority to exclude or remove any person from this area at any time.

Vistra OpCo conducts practices that provide knowledge of the approximate number and location of persons within the Exclusion Area engaged in such activities. Normal evacuation of persons within the Exclusion Area will take no more than two hours.

2.1.2.3 Arrangements for Traffic Control

In the event of an emergency, traffic on the plant access road will be controlled by Vistra OpCo.

If Squaw Creek Reservoir is opened to the public, arrangements will be made to control traffic in the event of an emergency (see Section 2.1.2.2, above).

2.1.2.4 Abandonment or Relocation of Roads

An unpaved county road which traversed the northeast corner of the Exclusion Area was abandoned in April 1975 because of the construction of Squaw Creek Dam and Reservoir. Arrangements for the closing of this section of road were made with the Somervell County Commissioner's Court in December 1974. No other public roads traverse the Exclusion Area.

2.1.3 POPULATION DISTRIBUTION

The purpose of this section is to provide detailed estimates of the present and projected size and distribution of population within a 50-miles radius of CPNPP. The population estimates provided in the PSAR have been reviewed, revised, and updated for purposes of the FSAR. Estimates of population distribution are provided for 1970 (most recent census year), 1976 (current year), and for census decades 1980 through 2020.

In reviewing and updating the population estimates in the PSAR, it was recognized that the actual centerline locations of the containment structures for Units 1 and 2 differ slightly (approximately 88 feet) from the locations as originally shown. In these revised population estimates, the actual centerline of the Unit 1 containment structure has been taken as the point of origin for the sector lines and concentric distance circles which form the sector-areas used in portraying population distribution within the 50-mile radius of CPNPP. While the 1970 county-by-county population base in the CPNPP area remains the same as shown in the PSAR, the slight difference in Unit 1 location causes some change in location of sector lines and distance circles. Thus, very small changes are found in this updated population study in the 1970 distribution of population by sector- areas.

The territory included within the 50-mile radius of CPNPP includes all or a part of 19 counties, all in Texas. The general location of CPNPP in Somervell County and the locations of the rest of the counties located within 50 miles of the plant site are shown in Figures 2.1-3 and 2.1-4. The population of these 19 counties is given in Table 2.1-1 for the census decades 1930 through 1970; in addition, the table provides an estimate of the 1976 population for each county and the projected future population for each census decade 1980 through 2020. Footnotes to the table provide brief comment regarding the sources of the historical data and the projections. Within the 50-mile radius of CPNPP, there is wide diversity in land use, urbanization, and population density. The plant site is located in Hood and Somervell counties, which are essentially rural, sparsely-populated areas. The entire population of Somervell County was 2,793 residents in 1970. Hood County, which is much larger in area than Somervell County (as may be seen in Figure 2.1-3), had a population of 6,368 inhabitants in 1970. In 1970, there were three small communities with a total of 4,339 people within the 10-mile area around the CPNPP site. The total population within the 10-mile area at that time was 5,353, or an overall population density of approximately 17 persons per square mile.

The sparsely-settled rural character extends well beyond the 10-mile radius, as indicated in Table 2.1-2, which lists all incorporated communities and all unincorporated settlements with over 1,000 inhabitants within the entire 50-mile radius of the site. The area extending from 10 to 20 miles out from the CPNPP site is even more sparsely populated than the 0 to 10-mile area. As the table shows, in 1970 there were two communities totaling 1,028 people within the entire 10 to 20-mile area around the CPNPP site, and the total population in this area was 7,532 (this is a 1970 population density of only 8 persons per square mile). Beyond the 20-mile radius there are more communities, and the 30 to 50-mile area to the northeast is dominated by the Fort Worth metropolitan complex.

In reviewing the county-by-county population projections which were given in the PSAR, it was found that most of the county population projections should be revised somewhat in accordance with current population estimates and the most recent projections prepared by the councils-of-government and the state agencies. Accordingly, in providing updated county population data (Table 2.1-1), current estimates for 1976 are given along with the revised projections for the years 1980 through 2020. It should be noted that the current estimates and the projections of expected population growth in Hood and Somervell counties are based upon an enumeration of housing units in the two counties in mid-1976 and an updated evaluation of recent and probable future trends in recreational development in the local area. Moreover, the estimates for Hood and Somervell counties include detailed consideration of the current and possible future impact of CPNPP construction and operation on population growth. As a general procedure in determining population distribution, the 1970 population of each county (wholly or partially within the 50-mile radius of the plan) was allocated to sector-areas within the county on

the basis of (1) the population of each community and enumeration district located wholly within a particular sector-area, and (2) a percentage share of the population of each enumeration district and community partially within a particular sector-area (the percentage share of population of an enumeration district to be allocated to a particular sector-area was generally assumed to be equal to the percentage portion of the area of the enumeration district within the particular sector-area).

In the case of Hood and Somervell counties, the county and enumeration district populations were allocated to sector-areas on the basis of (1) an actual count of housing units within each sector-area, and (2) the estimated number of residents per housing unit, considering available census data for the particular local area. The housing count for Hood and Somervell counties for the PSAR was made in 1973 utilizing a combination of available mapping, aerial photography, and field survey resources. The housing unit count made in mid-1976 for the FSAR was based on a comprehensive field survey and housing enumeration for all of Hood and Somervell counties. The estimates of population within individual sector-areas have been reconciled to the population totals for each county (or a portion of a county).

The percentage ratio of the total population of a county which was estimated to be within each individual sector-area in the county in 1970 (1976 in the case of Hood and Somervell counties) was assumed to remain the same in 1980 and beyond. This assumption was made after concluding that there is little possibility of a significant and radical change in the basic pattern of current population distribution within individual counties in the 50-mile area.

2.1.3.1 Population Within 10 Miles

The area within the 10-mile radius of CPNPP is predominantly a rural agricultural area. In 1970, there were three small communities having more than 100 residents. The total population of Hood and Somervell counties changed little over the period from 1930 to 1970 (see Table 2.1-1).

2.1.3.1.1 Current Population Within 10 Miles

Since 1970, Hood and Somervell counties have experienced increases in population, as indicated by the following:

	Population	
County (and Community)	1970 (census)	1976 (estimate)
Hood County	6,368	15,601
Granbury (county seat)	2,473	3,526
Tolar	312	435
Somervell County	2,793	5,216
Glen Rose (county seat)	1,554	2,790

The estimates for 1976 are based upon the July/August 1976 enumeration of housing units in the two counties (including the communities). The growth of Granbury may be understated in

comparing the data above because much of the urban growth of the community has taken place beyond the city limits.

The increase in population of Hood County since 1970 is largely related to the attractions of Lake Granbury for residential developments. These developments are attracting large numbers of permanent residents as well as vacation and recreational visitors. In 1970, there were 2,628 housing units in use as permanent residences in Hood County. By 1976, there were 5,566 housing units accounting for an estimated population of 15,601 full-time residents in Hood County and there were an additional 1,648 housing units in use primarily during weekends and vacations. A significant portion of the increase in housing units has been in mobile homes used both as vacation homes and permanent residences. The increase in permanent residents in Hood County is partially accounted for by attractive living conditions; many people that have moved into Hood County are commuting to jobs elsewhere. Significant numbers of retired people have established their permanent residence in Hood County. With the above, and the general stimulus of vacation and recreational activity, there has been an increase in local economic activity and job opportunity within the county.

The number of permanent housing units in Somervell County increased from 1,203 in 1970 (but only 1,035 households at that time) to an estimated 1,856 housing units in 1976. An additional 26 vacation homes were located in the housing enumeration, but as the data indicates, virtually the entire housing inventory of Somervell County (fixed structures, mobile homes, and apartments or courts) was permanently occupied in mid-1976. Somervell County has participated only peripherally in the Lake Granbury stimulus to housing development and recreational activity.

In addition to the foregoing, it should be noted that the influx of construction workers employed on CPNPP accounts for a significant portion of the population increase from 1970 to 1976, particularly in the case of Somervell County. For example, at the end of July 1976, there were 2,285 workers regularly employed at the CPNPP construction site. Of that number, 216 had moved into Somervell County specifically to work at CPNPP. In addition to the 2,285 man active work force as of the end of July 1976, there was a total of 1,968 workers who had been terminated since the start of construction on CPNPP in October 1974. Of these terminated employees, 177 had moved into Somervell County for the purpose of employment at CPNPP. Data on the CPNPP work force indicates that, on the average, each worker had 1.8 dependents. Thus, considering both active and terminated workers, a total of 1,100 workers and dependents had moved into Somervell County as of July 1976.

The tabulation below provides a summary showing the total number of CPNPP workers who have moved into Hood and Somervell counties through July 1976:

	Total No. of Workers as of July 1976	
	Active	Terminated
Total (on-site work force)	2,285	1,968
Residing in Somervell County:		
Local Hire	160	138

	Total No. of Workers as of July 1976	
	Active	Terminated
Relocated	216	177
Residing in Hood County:		
Local Hire	278	240
Relocated	201	173

The total number of workers (both active and terminated) and dependents relocating to Hood and Somervell counties through July 1976 is estimated as follows:

	Total Workers	Dependents	Total
Hood County	374	673	1,047
Somervell County	393	707	1,100

While 45 to 47 percent of these totals are represented by now terminated CPNPP employees and dependents, there are strong indications that a large portion of the terminated employees who originally moved with their dependents into the local area to work on CPNPP actually stayed in the area after termination of employment at CPNPP. The overall growth of population in both counties is creating increasing opportunities for employment in local service industries. Moreover, as indicated earlier, substantial numbers of new residents in Hood and Somervell counties are commuting to jobs outside the local area.

Table 2.1-3 shows estimated population distribution by sector and mileage zones within 10 miles of CPNPP for the years 1970 and 1976 and for the census decades 1980 through 2020. Figure 2.1-3 indicates the location of the plant in Somervell County and the sector areas out to a 10-mile radius. As may be seen from the data in the table, a substantial part of the increase in population in the two counties from 1970 to 1976 has occurred in or near the established communities. The population of the remainder of Somervell County has increased by an estimated 95 percent over the same period (1970-1976) and examination of the data in the table indicated that this growth was widely distributed in the county.

In some contrast to Somervell County, the population growth in Hood County has been more highly concentrated (in the areas near Lake Granbury). The population of the county seat of Granbury (within the city limits) increased by an estimated 42 percent from 1970 to 1976. The population of the balance of Hood County increased by well over 300 percent. Much of this increase has occurred in the north, north-north-east, and northwest sectors in the 5 to 10-mile area and the 10 to 20-mile area. These increased concentrations of population within particular sector-areas in Hood County are clearly evident in a comparison of the 1970 and 1976 data in Table 2.1-3.

2.1.3.1.2 Projected Population Within 10 Miles

The size and distribution of population within 10 miles of the CPNPP plant site as projected for the census decades 1980 through 2020 are shown in Table 2.1-3 (along with estimates for 1970 and 1976). These projections of future population distribution within the 10-mile radius of the site are fully reconciled to the overall population projections for Hood and Somervell counties (as described earlier). These projections take into account the size and residential distribution of the CPNPP construction work force and the expected phase-out of construction activity over the period 1980-1982.

It is expected that the continued growth of population and employment opportunities associated with lake-oriented residential community development and recreational activities in Hood County will tend to offset the sharp drop in construction employment on CPNPP. It is also expected that the completion of CPNPP will cause an actual decline in population in Somervell County after 1980 (for a period of two to three years), but by 1990 the loss will be regained due to the underlying slow rate of growth expected for the county.

2.1.3.1.3 Age Distribution of Population Within 10 Miles

To provide an estimate of the population by age groups, it was necessary first to compare the 1970 population distribution by age group for Somervell County and the U.S. as a whole. Because the percentage distribution by age groups 0 to 11, 12 to 18, and 19 and over for Somervell County and for the U.S. for 1970 differed by less than 10 percent, the distributions for the year 2000 for the project area were assumed to be the same as the Bureau of Census age-group distribution projections for the U.S. for the year 2000. If the difference had been greater than 10 percent, the U.S. percentages would have required adjustment based on projections for the North Central Texas region.

The U.S. projection for the year 2000 came from Table No. 3 of the “U.S. Statistical Abstract, 1975.” The data had to be modified slightly, however, to compensate for somewhat different age groupings. The population projection for the 10-mile area of CPNPP came from Table 2.1-3. The resulting population distribution by age group for the 10-mile area around CPNPP for the year 2000 (the mid-point of expected plant life) is given in Table 2.1-4.

2.1.3.2 Population Within 10 to 50 Miles

The population within the 10 to 50-mile radius of CPNPP includes the population of a large number of communities and cities including Fort Worth, as listed in Table 2.1-2. The location of all population centers is shown on Figure 2.1-4, which also shows sector lines and distance circles out to the 50-mile radius from CPNPP.

2.1.3.2.1 Current Population Within 10 to 50 Miles

The distribution of the 1970 population and the estimated 1976 population within the 10 to 50-mile radius of CPNPP is shown by sector-area in Table 2.1-5. The estimates of population distribution by sector-area for 1976 are correlated with the county-by-county projections, as described earlier. There was a 13.4 percent increase in population within the entire 10 to 50 mile area from 1970 to 1976 (compared with the 127 percent increase within the 10-mile area). Within the 10 to 50-mile area there are significant differences among counties with respect to population increase (or loss) from 1970 to 1976 as may be seen in reviewing Table 2.1-1. For

example, the population of Johnson County (to the east of the site) increased by 20 percent while Stephens County (to the west of the site) decreased by 3 percent. These differences in recent growth trends among the counties are reflected in the estimates of current population distribution by sector-area.

2.1.3.2.2 Projected Population Within 10 to 50 Miles

The present and projected population growth through the year 2020 is shown by county in Table 2.1-1 for all counties within the 50-mile radius of CPNPP. Table 2.1-5 provides estimates of the distribution of projected population by sector-area for the census decades 1980 through 2020 (along with comparable estimates for 1970 and 1976). As may be seen in a comparison of the cumulative estimates of population for 0 to 10 miles, 0 to 20 miles, etc., for each of the census years (summarized at the end of Table 2.1-5), population growth for the entire 0 to 50-mile area is projected to increase at a much slower rate than for the 0 to 10-mile area, as shown below:

Area (radius)	Population (000)		Percent Increase
	1976	2020	
0-10	12.1	31.1	156
0-20	24.7	64.9	163
0-30	83.8	198.5	137
0-40	438.8	1,024.8	134
0-50	894.0	2,090.5	134

2.1.3.2.3 Age Distribution of Population Within 10 to 50 Miles

The age distribution of the population of Somervell County (in which the plant is located) in 1970 differed by less than 10 percent from the 1970 age distribution for the populations of the United States as a whole. Accordingly, the projected percentage age distribution for the United States for the year 2000 (mid-point of plant life) was assumed for the population within the 10 to 50-mile area around CPNPP for the year 2000. The projected populated distribution by age group for the 10 to 50-mile area is provided in Table 2.1-6.

2.1.3.3 Transient Population

After consideration of the overall patterns of settlement, land use, and population distribution within the entire 50-mile radius of the site, it was concluded that transient population movements and daily and seasonal variations in population distribution and concentration within the 10-mile radius of CPNPP should be examined in some detail. It was also concluded that no such examination and projections should be made of transient movements in the 10 to 50-mile area. There are large-scale movements of daily commuters (in all directions) within the Fort Worth metropolitan complex. However, but the potential significance and meaning of such movements (compared with the potential significance of movements within the 10-mile area) does not appear to justify the inordinate effort that would be required to characterize, analyze, and project transient population movements within the 10 to 50-mile area. Accordingly, the discussions below pertain only to transient population within the 10-mile radius of CPNPP.

2.1.3.3.1 Seasonal Variation

This category of transient population is specifically concerned with overnight visitors coming into the 10-mile area. As will be shown, there are many more overnight visitors in the summer season than during other times of the year, but overnight visitors are found in the area throughout the year. The seasonal or overnight category of transients includes visitors staying for several days or weeks (this category excludes consideration of daily transients, regardless of the season). This category of transient population (seasonal or overnight visitors) includes visitors that would be found in hotel/motels, camp-grounds, recreational vehicle parks, organized camps (church groups, youth groups, etc.), mobile home-parks, and vacation homes. It also includes live-in students in a children's home despite the fact that their stays are for extended periods. These children are not included as part of the permanent population.

Because this category of transients is predominantly comprised of recreational and vacationing visitors, there is a distinct peaking in the summer season of total transients in the area at any one time. Moreover, normal and holiday weekend peaking is different and week- days differ from week-ends, both in summer and winter. See Table 2.1-7 for estimates of the length of stay of various types of transients.

In developing the estimates of seasonal transient population given in Table 2.1-8, consideration has been given to (1) the location and capacity of various facilities that accommodate overnight visitors, and (2) the actual patterns or levels of use which are typically experienced by the facilities at various time of the year. The table presents estimates of weekly, typical weekend and holiday week, and daily and overnite transient during summer and winter.

With respect to the projection of future levels of seasonal or overnight transients, different assumptions were made for the several different types of facilities. Sector-area estimates of vacation home and hotel/motel visitors were assumed to increase from 1980 through 2020 in proportion to the projected increase in population for the county as a whole (in which the sector-areas are located). Organized camp attendance is expected to remain at 1976 levels and the children's institution will remain stable from 1980 onward. Camping at various types of facilities along Lake Granbury is expected to reach its peak by 1990 (achieving levels similar to those at other older facilities in North Central Texas) and level off thereafter. Camping elsewhere in the 10-mile area (away from Lake Granbury) was estimated to grow in general accordance with the population growth projected for Dallas and Tarrant counties (major counties in the larger metroplex).

2.1.3.3.2 Daily Variation

This category of transient population is concerned with daily movements of population into and within the 10-mile area and peaking in the number of transients found in a particular sector-area at any given time. Estimates of daily transient movements and population concentration include consideration of movements to such facilities as public schools, private schools, urban and community shopping centers, and recreational facilities such as parks and lakes. Estimates have been made of daily visitor recreational use of Lake Granbury (in addition to use by overnight and vacationing visitors). Beginning in 1980, when it will have been filled, it is assumed that limited daily visitor recreational use will be permitted at a non-camping park facility on Squaw Creek Reservoir.

It is apparent from Table 2.1-8 that there are great differences in daily transient population movements depending on the season of the year and on the time of the week (weekday, normal weekend, and holiday weekend). It should be noted that the table does not provide estimates of the total number of daily visitors (of different types) but rather it provides estimates of the maximum number of visitors that might be expected in a sector-area during the peak hours of the day. It is also important to note that the estimates of peak daily transient population concentration in a particular sector-area are not accompanied by corresponding decreases in population in sector-area from which the transients originated. This is the situation where large numbers of school children (from numerous sector-areas) are concentrated daily in a single sector-area. This is simply a recognition that peak population concentration in different sector-areas may occur at different times of the day.

The general approach in estimating daily transient movements in 1976 was to utilize empirical data wherever possible, as in the case of school enrollments and the daytime use of some recreational and park facilities. The experience of state parks and other older reservoirs and water-oriented facilities was used as a basis for estimating current and projected daytime use of Lake Granbury and Squaw Creek Reservoir. The numbers and movement patterns of permanent and vacation residents in making use of shipping facilities in Granbury and Glen Rose was estimated on the basis of the geographical distribution of households and a number of working assumptions regarding the frequency and time of week for shoppers coming from various distances. It was assumed that the above communities served only the areas of their respective counties. Again, the estimates indicate the peak number of transients that would be in a sector-area at a particular time and not the total number of transients during a day.

With respect to the projections of daily transients for future years, several assumptions were made as in the case of the seasonal population estimates. Projections of daily transients associated with school enrollments and community shopping activity were related to basic population projections. Recreational use of Lake Granbury and Squaw Creek Reservoir was assumed to reach mature levels by 1990 and level off thereafter at levels found at similar, but older, water-related facilities elsewhere in North Central Texas. It is noted that Unit 2 of CPNPP will not be completed until 1982 or thereafter and that a construction work force will remain on site after completion and start of operations (at least in a test mode) of Unit 1 in late 1980.

2.1.3.3.3 Summary Effect of Transient Population Movements in 10-Mile Area

The most conservative estimate of area population, provided in Table 2.1-9, is the sum of the permanent population and the maximum transient population estimate (summer holiday weekend daily transients). Similar estimates for other transient periods may be obtained by simply summing the permanent population estimate (Table 2.1-4) and the appropriate transient population estimate. Comparison of Table 2.1-4 and 2.1-9 shows that inclusion of the maximum transient population increases total population by nearly 60 percent.

2.1.3.4 Low Population Zone

In accordance with 10 CFR Part 100 guidance, the low population zone shown in Figure 2.1-5 is defined as that area falling within a four-mile radius of the center of the station site. The present number of residents (approximately 500 persons according to the 1976 estimate) within this area is sufficiently small to ensure a reasonable probability that appropriate protective action could be taken in their behalf in the event of a serious accident as required by 10 CFR 100.3. Section 15.6 shows that this area is of sufficient size to preclude an individual located on its outer

boundary from receiving a total dose following a postulated accident in excess of requirements in 10 CFR Part 100.11. Resident and transient populations within the zone have been discussed in detail in Sections 2.1.3.1 through 2.1.3.3.

2.1.3.5 Population Center

The nearest population center (defined in 10 CFR Part 100 as more than 25,000 people) is Fort Worth, Texas. According to the 1970 census, Fort Worth has a population of 393,476 people (approximately 613,000 in metropolitan area). The growth rate was 10.4 percent between 1960 and 1970. The geographic center of Fort Worth, which is approximately 41 miles northeast from CPNPP, does not differ significantly from its population center. Dallas, with 844,401 inhabitants (1,555,950 in metropolitan area), is 67 miles northeast of the station. Cleburne, 23 miles east of the station site with a population of 16,015 people is the next largest community in the area. Cleburne is expected to reach a population of 25,000 by the mid 1980's, thus becoming the nearest population center as defined by 10 CFR Part 100.

2.1.3.6 Population Density

The cumulative resident population projected for the year of initial plant operation (1980) is compared with a cumulative population resulting from a uniform population density of 500 people/square mile in all directions from the plant in Figure 2.1-6. A similar comparison is made for the end of plant life (2020), but compared with a cumulative population resulting from a uniform population density of 1,000 people/square mile in Figure 2.1-7.

TABLE 2.1-1
HISTORICAL AND PROJECTED POPULATIONS FOR COUNTIES WITHIN
50 MILES OF CPNPP

(Sheet 1 of 3)

County	1930	1940	1950	1960	1970
Bosque	15,750	15,761	11,836	10,809	10,966
Comanche	18,430	19,245	15,516	11,865	11,898
Coryell	19,999	20,226	16,284	23,961	35,311
Dallas	325,691	398,564	614,799	951,527	1,327,321
Eastland	34,156	30,345	23,942	19,526	18,092
Ellis	53,936	47,733	45,645	43,395	46,638
Erath	20,804	20,760	18,434	16,236	18,141
Hamilton	13,523	13,303	10,660	8,488	7,198
Hill	43,036	38,355	31,282	23,650	22,596
Hood	6,779	6,674	5,287	5,443	6,368
Jack	9,046	10,206	7,755	7,418	6,711
Johnson	33,317	30,384	31,390	34,720	45,769
McLennan	98,682	101,898	130,194	150,091	147,553
Palo Pinto	17,576	18,456	17,154	20,516	28,962
Parker	18,759	20,482	21,528	22,880	33,888
Somervell	3,016	3,071	2,542	2,577	2,793
Stephens	16,560	12,356	10,597	8,885	8,414

Sources:

a. Historical data for 1930-1970 are from US Bureau of Census.

b. Estimates for 1976 for Hood and Somervell Counties are based on a comprehensive enumeration of housing units by Westwood Research, Inc.

TABLE 2.1-1
HISTORICAL AND PROJECTED POPULATIONS FOR COUNTIES WITHIN
50 MILES OF CPNPP

(Sheet 3 of 3)

c. Estimates for 1976 for counties other than Hood and Somervell, are derived from the long-term trend lines considering historical data through the 1970 Census and long-term projections described below.

d. The long-term projections of population growth in all counties are projections made by various local councils of governments and Texas state agencies. Where there are significant differences in projections made by different authorities for the same county, recent experience and current and short-term trends have been considered in selecting the long-term projections for inclusion in the table.

a) Communities include all unincorporated settlements with 1,000 or more inhabitants, and all incorporated communities.

b) Source is the US Bureau of Census (Ref. 2.1-1).

c) Distances are indicated to the nearest and most distant portion of the densely settled area of a community rather than to city limits, as such. Beyond 20 miles the distance is rounded to the nearest mile.

d) Population of the community is located partly outside of the 50 mile radius of CPNPP.

TABLE 2.1-4
POPULATION DISTRIBUTION BY AGE GROUPS WITHIN 10 MILE RADIUS OF CPNPP FOR YEAR 2000

(Mid point of plant life)

	Population	
Age Groups	Number	Percentage[a]
0-11	4,807	22.6
12-18	2,843	13.4
19 and over	13,628	64.0
	21,278[b]	100.0

a) As specified in Appendix D of the Regulatory Guide 4.3, Revision 2, a “test of significance” was made comparing the 1970 population distribution by age groups of Somervell County with that of the United States as a whole. The test indicated that the two distributions differed less than 10 percent. Thus, the percentages in the table above are based on the unadjusted population distribution by age groups as projected for the United States in the year 2000. The United States projection of the population by age groups is found in Table No. 3 of the Statistical Abstract of the United States, 1975 (Ref. 2.1-3).

b) Population total of the area 0 to 10 miles for the year 2000 is from Table 2.1-3

TABLE 2.1-6
POPULATION DISTRIBUTION BY AGE GROUPS BETWEEN 10 AND 50 MILE RADIUS OF CPNPP FOR YEAR 2000

(Mid point of plant life)

	Population	
Age Groups	Number	Percentage[(a)]
0-11	322,791	22.6
12-18	191,390	13.4
19 and over	914,090	64.0
	1,428,271	100.0

a) As specified in Appendix D of the Regulatory Guide 4.3, Revision 2, a “test of significance” was made comparing the 1970 population distribution by age groups of Somervell County with that of the United States as a whole. The test indicated that the two distributions differed less than 10 percent. Thus, the percentages in the table above are based on the unadjusted population distribution by age groups as projected for the United States in the year 2000. The United States projection of the population by age groups is found in Table No. 3 of the Statistical Abstract of the United States, 1975 (Ref. 2.1-3).

b) Population total of total area between 10 miles and 50 miles for the year 2000 is from Table 2.1-5.

TABLE 2.1-7
TYPE AND TYPICAL LENGTH OF STAY OF TRANSIENTS WITHIN 10 MILE RADIUS OF CPNPP

Type of Transients	Typical Length of Stay
Overnight Transients (Seasonal Visitors)	
Camping (Campgrounds and RV Parks)	Winter visitors for weekends Summer visitors for one week
Childrens' Institution	Indefinite[(a)]
Hotels/Motels	Two days
Organizational Camps	Winter campers for weekends Summer campers for 1 to 2 weeks
Vacation Homes	Winter visitors for weekends Summer length of stay cannot be specified for lack of data
Daily Transients	
Childrens' Institution	Eight hours
Recreation (Parks and Lakes)	Four hours
Schools	Eight hours
Shopping Centers	Three hours

a) The children of the institution are listed as transients because they are not included in the estimate and projections of the permanent population. Some students are live-in and some attend day only.

2.2 NEARBY INDUSTRIAL, TRANSPORTATION AND MILITARY FACILITIES

2.2.1 LOCATIONS AND ROUTES

Investigation has been undertaken to locate all significant manufacturing plants; chemical plants; refineries; storage facilities; mining and quarrying operations; military bases; missile sites; transportation routes (air, land, and water); transportation facilities; oil and gas pipelines, drilling operations and wells; and underground gas storage facilities. The search included military firing ranges, and nearby airplane high and low-level flights and landing patterns (commercial, general aviation and military).

The CPNPP vicinity is essentially devoid of most of these features. Within the 10-mile area, there are no military bases, missile sites, military firing ranges, munitions facilities, airport approaches, chemical plants, and storage facilities, tank farms or upstream sources of corrosive or oil discharges. The nearest military bases are Carswell Air Force Base, approximately 38 miles north-northeast, and Fort Hood, approximately 65 miles south. There are no missile sites within 50 miles. The nearest manufacturing facility is a textile plant in Granbury, 10 miles north.

Principal transportation routes extending to within 10 miles of the Station site consist of two U. S. highways and one state highway, one railroad, eleven air routes (refueling tracks and Victor lanes), three gas transmission pipelines, and one crude oil transmission pipeline. Air routes out to more than 20 miles are shown on Figure 2.2-1; other transportation routes can be seen in Figure 2.1-5.

No heavily traveled highways pass close to the site. All nearby roads have one or two lanes and have relatively light traffic (Figure 2.1-5). The nearest highway is State Highway 144, 2.5 miles northeast. The closest approach to U. S. Highway 67 is approximately 4.5 miles south-southwest, and the nearest approach to U. S. Highway 377 is nine miles north-northeast. The Atchinson, Topeka and Santa Fe Railroad nearest approach is about 9.5 miles to the northwest.

2.2.2 DESCRIPTIONS

2.2.2.1 Description of Facilities

The only industrial, transportation, or military facilities within five miles of the site are the transportation corridors shown on Figures 2.1-5 and 2.2-1. Furthermore, there are no industrial, transportation or military facilities at greater distances which are significant to CPNPP from a safety standpoint.

2.2.2.2 Description of Products and Materials

The only hazardous materials (excluding local gas stations and materials not directly related to CPNPP) regularly manufactured, stored, used, or transported in the site vicinity are crude oil and natural gas transported through the pipelines described in Section 2.2.2.3.

2.2.2.3 Pipelines And Wells

The four pipelines traversing the site vicinity are described in Tables 2.2-1 and 2.2-2; their locations are shown in Figure 2.5.1-17. Two of the pipelines (the West Texas Gulf crude oil line

and the Lone Star Gas Company line) were relocated around Squaw Creek Reservoir to avoid the immediate Station and reservoir areas. The relocated routes are shown on Figure 2.1-2b.

Figure 2.5.1-17 also shows the location of gas and oil wells within five miles of CPNPP.

2.2.2.4 Waterways

Squaw Creek Reservoir (SCR) is a 3,272 acre cooling reservoir located on Squaw Creek (see Section 2.4), which is not used for navigation. A Safe Shutdown Impoundment (SSI) on the Panther branch of SCR impounds water for the Station Service Water System as described in Sections 2.4 and 9.2.5.

2.2.2.5 Aircraft

2.2.2.5.1 Airports

There are no airports within five miles of the Station. Furthermore, there are no airports with greater than 500 d^2 ("d" is the distance in miles from the Station) movements per year within 10 miles, nor are there any airports with projected operations in excess of 1000 d^2 movements per year within 50 miles.

The nearest landing field (Bar L Ranch) is a sod strip located six miles west-southwest of the site. There are several other sod strips within 20 miles of the site, but the only paved strips are Nassau Bay (private), Pecan Plantation (private), and the Granbury Municipal Airport. The Granbury Municipal Airport (11 miles north-northwest) has a lighted 2,000-foot paved runway, but there are no regularly scheduled commercial flights.

2.2.2.5.2 Air Routes

Eleven air routes pass within 10 miles of the site. Three of these routes are military refueling tracks (flight levels: 24,000 to 31,000 feet) having 10 nautical-mile wide paths (Figure 2.2-1). The outer limits of all three refueling tracks miss the Station site; their nearest approach to the site is the north edge of AR-102B (East), located 1.7 miles south. The north edge of AR-102B (West) is the next closest refueling track, 2.5 miles south. The closest approach of the south limit of AR-102 A (East) is 8.5 miles north of the Station.

The other air routes are Victor lanes which (Figure 2.2-1) are cleared for general, commercial and military aviation. Victor 163W and Victor 163 air lanes are the only routes which pass within 2 miles of the Station location.

The probability of an aircraft crashing into the plant (PFA) is estimated in the following manner:

PFA = C * N * X * (A/B)

where:

C = inflight crash rate (crashes per mile),

N = number of flights per year in the air sector,

X = flight distance in passing possible collision area,

A = effective area of plant, and

B = possible collision area

For CPNPP:

C = 1.14 x 10-9 crash/mile,

N = 130,104 flights/year,

X = 12.63 miles

A = 0.02 square miles,

B = 314.16 square miles.

Therefore, $P_{FA} = 1.91 \times 10^{-7}$. This probability is sufficiently low that an aircraft crash into the plant is not considered a design basis.

2.2.2.6 Projections of Industrial Growth

Industrial growth includes the Station and related pipelines, transmission lines, railroad spur, and access roads. With the exception of natural gas exploration, no industrial growth can reasonably be expected to occur in the site vicinity.

2.2.3 EVALUATION OF POTENTIAL ACCIDENTS

The nearby industrial, transportation, and military facilities described above were evaluated for their potential effects on the station in order to identify potential accidents to be considered as design basis events. In addition, the onsite storage of chlorine was evaluated for its effect on control room habitability as described in Section 6.4.

2.2.3.1 Determination of Design Basis Events

Events which potentially qualify as design basis events were categorized by the physical effects which accompany the accident.

2.2.3.1.1 Explosions

There are no offsite sources of explosive materials in the vicinity and transportation routes do not approach CPNPP within the distance prescribed by Reg. Guide 1.91 [8].

[redacted]

An explosion, therefore, is not considered a design basis event.

2.2.3.1.2 Flammable Vapor Clouds

The three natural gas pipelines in the site vicinity could be a source of flammable vapor clouds and were evaluated for their potential effects on the plant.

The gas wells in the site vicinity, described in Section 2.5.1, could also be a source of flammable vapor clouds and were evaluated for their potential effects on the plant. Since exploration in the area is still active, a hypothetical gas well was postulated using data available from the Texas Railroad Commission. A discussion of this hypothetical well is provided in Section 2.5.1.

2.2.3.1.3 Toxic Chemicals

Toxic chemicals which are stored and used onsite at CPNPP are evaluated in accordance with the criteria and guidance of Regulatory Guide 1.78 and NUREG 0570.

2.2.3.1.4 Fires

The only non-plant-related source of fire in the vicinity of CPNPP is the crude oil pipeline. The rupture of this pipeline was evaluated for its potential effect on the plant.

2.2.3.1.5 Collision with Intake Structure

The Service Water Intake Structure is located on the Safe Shutdown Impoundment (see Figure 1.2-1), which is not open to public transportation. Therefore, a significant collision with this structure is not considered a credible event.

2.2.3.1.6 Liquid Spills

The only source of liquid spills in the vicinity of CPNPP is the crude oil pipeline which was evaluated for its potential effect on the plant.

2.2.3.2 Effects of Design Basis Events

The design basis events identified above are:

1. Gas Pipeline and Gas Well Accidents

2. Accidental Release of Toxic Chemicals

3. Crude Oil Pipeline Rupture

Each of these is evaluated below.

2.2.3.2.1 Gas Pipeline and Gas Well Accidents

Potential accidents involving the release of natural gas from existing pipelines and postulated wells described in Section 2.2.2 do not pose a hazard to the plant. As shown below, in the event of an accident the concentration of gas at all plant air intakes is well below the lower flammability

limit. Also detonation of an unconfined natural gas-air mixture is not considered to be a credible event [1,2,3,4].

Each of the existing pipelines and a potential gas well were analyzed to determine the most limiting potential accident condition; the results of this analysis indicated that the most limiting release of natural gas would involve a break in the 36-inch Lo-Vaca natural gas pipeline. The analysis of this accident was performed using the following conservative assumptions:

1. [redacted]

2. Gas is released by a constant enthalpy process yielding a gas temperature for dispersion calculations of 40°F (for a 60°F initial gas temperature) due to the Joule-Thompson effect.

3. The flowrates out of the break is the maximum steady flow for single-ended break (572 m^3/sec) and a double-ended break (1144 m^3/sec).

4. Atmospheric dispersion factors were based on the 5-percentile meteorological conditions from onsite data analyses with a virtual source distance correction to account for initial finite source size.

5. A conservatively low wind speed of 1.0 m/sec was used.

6. Plume rise is in accordance with Briggs equation for stable (classes F and G) atmospheric conditions [5] and an air temperature of 100°F.

A perfect gas prior to its escape from the broken pipe will expand and accelerate toward the break. As the gas expands, it will tend to cool down from its original equilibrium temperature. In doing so, a temperature gradient between the pipe and the flowing gas will be established. In addition, friction between the pipe wall and the flowing gas will tend to heat the gas slightly above the temperature it would possess in a frictionless expansion. In the first instance, small amounts of heat will flow from the pipe wall into the expanding gas and in the other, energy already possessed by the gas is simply transformed into heat and causes the gas temperature to rise slightly more. Thus, the gas gains a small amount of energy from the pipe wall during this process.

In the second part of the blowdown process, the gas expands through the break at sonic velocity and, if still above atmospheric pressure, continues to expand until it reaches atmospheric pressure. During this phase, the process is essentially adiabatic. No work is performed either during the expansion or the slowing down period. Consequently, the net energy possessed by the gas just prior to reaching the break, and after it slows down in the atmosphere, remains unchanged.

Since (1) no work has been performed by the escaping natural gas, (2) small quantities of heat have been transferred from the pipe to the gas, and (3) a transformation of energy has occurred by virtue of the fact that the gas is at a substantially lower pressure at the end of the blowdown, the energy gain from (2) above and the energy transformation indicated in (1) above must be present in the form of heat. Therefore, the slowed down natural gas in the atmosphere would be at a slightly higher temperature than the original temperature. The blowdown is therefore, in

essence, a throttling or isenthalpic process. Since natural gas is a real gas, not a perfect gas, the Joule-Thompson effect will cause the natural gas to be about 20°F below that expected for a perfect gas after blowdown.

The above description of the process indicates that there is a tendency for a perfect gas after the blowdown and mixing phase to be at a slightly higher temperature than the original temperature. However, with real gases, this temperature increase is lessened or, perhaps, reversed slightly. Therefore, extra conservatism is introduced into the plume rise analysis by assuming that the natural gas does not mix thermally with air and is cooled isenthalpically 20°F below the temperature it possessed prior to the break.

The flowrate was found using the American Gas Association gas pipeline formula [6] using an initial upstream pressure of 1050 psig, a final (downstream or break) pressure of 14.7 psia, and pipe length of 70 miles. This length is the distance from the break to both the upstream and downstream compressors.

Dispersion of potentially explosive gas vapors resulting from a gas pipeline rupture is governed by meteorological conditions existing in the locality at the time. This analysis used design basis accident meteorological assumptions determined for a radioactive release in the analysis of a flammable and/or explosive structure. The design basis accident assumption doses were calculated using conditions which conservatively calculate radioactive cloud concentrations, i.e., those conditions which minimize diffusion of the cloud. The conditions assume five percentile dispersion factors as an analysis basis conservatism. The Dispersion calculations also conservatively assumed that there was no momentum flux in the plume rise calculation. In reality, because the pipe is below grade, the gas would be expected to have a significant vertical velocity component. This would tend to carry the plume higher than calculated. Atmospheric dispersion factors and the model used for virtual source correction are discussed as part of the description of the gas well blowout hazard analysis at the end of this section (2.2.3.2.1).

[redacted]

Though a sustained gas fire may occur at or near the gas well head, a gas well fire at the closest point where mineral exploration may be permitted has negligible heat effects on the nearest safety-related structure, and no effect on safety-related structures due to the release and delayed ignition of non-buoyant natural gas components such as ethane and propane. Conservatively estimating all the heat from a gas well blow out to be radiated isotropically, the resultant sustained incident energy on the surface of a sphere 2250 feet away gives a heat flux loading of about ten percent of the maximum solar insolation at the site. The heated air would rise clear of the plant at low wind speeds, while a strong wind is needed to keep the buoyant heated plume near the surface. These conditions imply ventilation and mixing sufficient to keep any temperature rise at the plant to a non-significant level.

Each Control Room fresh air intake is equipped with a smoke detector that will annunciate in the Control Room in the advent of elevated smoke levels. Their operation is discussed in Section 6.4.2.4 and 9.4.1.3. Thus, smoke effects from mineral explosion fires are responded to adequately in a manner similar to smoke from plant fires.

[redacted]

The atmosphere dispersion model used for the gas well blowout hazard analysis was the Gaussian plume model for centerline concentrations with ground level releases and the Pasquill-Gifford dispersion parameters for an assumed non-buoyant release. Atmosphere dispersion factors for an instantaneous release with a finite initial volume were calculated in accordance with Reg. Guide 1.78 [13]. Wind speed was selected to maximize the instantaneous concentration within the Control Room. Additional credit due to building wake effects was not included in the model. Also, the difference in height of the release point and Control Room inlet is not large enough to allow credit for an elevated release. Atmospheric dispersion factors for a continuous release are based on a 5-percentile meteorological conditions (such as Pasquill F at 1.0 meters/second) at the site. To establish these conditions, the 5-percentile x/Q's for each time period were first determined from the results of onsite dispersion modeling. See Section 2.3.4. Because approximately 30 percent of hourly observations at the plant site are in the Pasquill F

and G stability classes, a Pasquill F stability was assumed, and the wind speed was defined at the 5 percentile probability level of relative concentration. Having defined the 5-percentile wind speed and Pasquill Class for the three time periods of interest, x/Q values were then calculated at selected distances using these meteorological conditions. The parameters used were:

- Distance from plant to well: 2250 ft.
- Maximum postulated gas well blowout flow rate: 52.4×10^6 ft^3 day^{-1} (17.2 m^3 sec^{-1})
- Lower well gas flammability limit concentration: 4%
- Virtual source correction: 278 ft.

The assumption is that the concentration of the released gas at the break is limited to unity. To satisfy this requirement, the source is taken to be a virtual point located a distance away from the actual release point. From a table of the 5-percentile x/Q's for the plant, this value is found to occur at a distance of 278 ft. This then is effectively added to the plant-well separation distance as the virtual source correction term.

The flammable limit was calculated on a mole-fraction-weighted bases of all the components assuming they are mixed in the turbulent stream emitted from the well. The well gas composition used was:

Nitrogen	2.36 mole %
CO_2	0.55 mole %
Methane	73.97 mole %
Ethane	13.58 mole %
Propane	6.95 mole %
Iso-butane	0.88 mole %
N-butane	0.83 mole %
Iso-pentane	0.35 mole %
N-pentane	0.22 mole %
Hexanes plus	0.33 mole %

2.2.3.2.2 Accidental Release of Toxic Chemicals

A study has been performed to evaluate the potential for chlorine releases from offsite chlorine storage and transportation affecting control room habitability. This study revealed no chlorine storage locations or frequent chlorine transportation within a 5 mile radius of CPNPP in quantities that are large enough to require evaluation under the criteria of Regulatory Guide 1.78. Therefore, potential accidents involving the release of chlorine from offsite storage locations and transportation routes do not pose a significant hazard to control room habitability.

The circulating cooling water and service water systems will be chemically treated for control of biological growth with solutions of sodium hypochlorite and sodium bromide. The diluted sodium hypochlorite and sodium bromide solutions will not present a threat to control room habitability. No liquified chlorine will be stored within the site boundary in containers exceeding 150 lbs capacity. The only liquified chlorine that will be stored within the protected area will be in small quantities of 20 lbs or less to be used for laboratory purposes.

Other toxic chemicals which are stored and used onsite at CPNPP are evaluated for potential impact of their release upon control room habitability in accordance with the criteria and guidance of Regulatory Guide 1.78 and NUREG 0570. Toxic chemicals which are determined to be hazardous to control room habitability are controlled and detection instrumentation is provided, as appropriate.

2.2.3.2.3 Oil Pipeline Accidents

[redacted]

Gulf indicates that from experience the lower limit on immediate detection and isolation is 400 Bbl/hr.[10] Smaller leaks could be detected over a period of time and would result in the initiation of an immediate search for the leak. CPNPP personnel will monitor for oil accumulation in the three retaining ponds located between the pipeline and the westside of the SSI once per day ensuring that leaks smaller than 400 Bbl/hr do not go undetected for more than 32 hours.

[redacted]

[redacted]

Maximum Rate Case

[redacted]

Maximum Quantity Case

[redacted]

[redacted]

In order to prevent the spilled oil from reaching the SSI, three retaining ponds will be built between the pipeline and the SSI. These ponds will be designed to hold the maximum quantity of oil given above or 14,770 Barrels. Rain water accumulation in these ponds will be drained through an inverted weir to ensure capacity is available for the maximum oil spill quantity. These retaining ponds eliminate any potential hazards resulting directly or indirectly from the crude oil spilling onto the SSI surface.

With the crude oil being kept from the SSI by the retaining ponds, the only remaining potential impact on the plant would be from drifting vapor clouds. Potential toxic and flammable vapor effects have been considered as discussed below.

The crude oil carried in the pipe may contain hydrogen sulfide (H_2S) which is toxic gas. The pipeline operator has indicated that the maximum H_2S concentration is 80 ppm in air measured 2 3/4" above a crude oil sample at 60°F [9,11]. Further information from Gulf indicated the best available measurement of H_2S concentration in the crude is 250 ppm obtained by mass spectrographic techniques, while 400 ppm is obtained by other techniques.[11]

A conservative calculation of H_2S concentration in the CPNPP control room was made assuming:

1. All H_2S was released instantaneously from a leak of 13,500 Bbl/hr of crude oil containing 400 ppm H_2S.

2. This formed a continuous source of H_2S which is blown toward the plant with worst 5 percentile site atmospheric dispersion.

3. The control room air intake sees the resulting plume centerline concentration ($94 mg/m^3$) for 10 minutes (note that the pipeline leak flow only occurs for 2.5 minutes.)

4. Normal control room ventilation of 3000 CFM continues for the entire 10 minutes.

The resulting maximum concentration in the control room is 8.5 mg/m^3. This is less than the time weighted average threshold limit value of 15 mg/m^3 recommended by the American Conference of Governmental Industrial Hygienists.[12] The control room concentration and the outside air concentration are far below the R.G. 1.78[13] toxic limit of 750 mg/m^3.

Considering the conservative calculations and the adequate odor detection threshold of H_2S the oil pipeline is not a credible potential gas hazard.

Gulf Oil indicates that the crude oil in the pipeline may contain significant fractions of light hydrocarbons. The maximum light fraction concentrations are as follows:[14]

Methane	0.60%
Ethane	0.14%
Propane	0.92%
Butane	3.74%
Pentane	44.6%

As indicated above, the maximum oil spill quantity occurs for the 400 Bbl/hr spill rate. At this rate even if all the light fractions were vaporized instantaneously the maximum concentration at the nearest plant safety related structure would be 0.24% which is 15% of the mixture lower flammable limit of 1.6%. This result is for worst 5 percentile site meteorology and a distance of 2400 feet from the nearest retaining pond to the Service Water Intake Structure. This effectively assumes the spilled oil gets all the way to the retaining pond without losing any vapor, but when it does reach the pond all the volatile fraction is released immediately. This maximizes the vapor release rate and minimizes the source to plant distance.

For the maximum spill rate case two situations have been analyzed. The first is for vaporization from the oil accumulated in the retaining pond (conservatively assuming water in the pond). The second situation is for vaporization from the oil spill on land between the pipe and the retaining pond.

The rate of vaporization from the oil spill was determined from a heat balance equating the heat lost by evaporation to the heat gain from either the water or the soil plus heat from solar radiation.

The evaporation rate was determined from the mass transfer relationships of Bird, Stewart and Lightfoot.[15] The mass transfer coefficient was obtained from the heat/mass transfer analogy using forced convection flat plate correlations of Krieth.[16] The vapor phase composition was determined from the crude oil composition given above using two phase equilibrium ratios from Reference [17].

Heat transfer from water was determined assuming simple convection from the water at a maximum natural water temperature of 97ºF using a overall film coefficient of 100 Btu/hr ft^2 ºF. For a spill on land transient heat conduction from soil was considered utilizing a procedure which accounted for soil temperature variation with depth from a 135ºF initial surface temperature and

an initial oil temperature of 74°F. Solar heat flux of 365 Btu/hr ft^2 was used. These temperatures are for worst case daytime summer conditions. Temperatures at other times would be much less.

The results of the analysis indicate that on water the oil reaches a maximum temperature of 86°F with a maximum specific evaporation rate of 9.6 lb/hr ft^2. On land the oil reaches a maximum temperature of 77°F with a corresponding specific evaporation rate of 6.8 lb/hr ft^2. These values are based on the initial oil composition and do not reflect the reduction in evaporation rate which occurs as the more volatile fractions are evaporated. Also the maximum conditions on land last for only a very short time due to the continued cooling of the soil.

[redacted]

Pond Area (ft^2)	Distance from SSWS INTAKE (ft)	Concentration as fraction of LFL
1	[redacted]	[redacted]
2	[redacted]	[redacted]
3	[redacted]	[redacted]

[redacted]

From the above discussion it is concluded that vapors released from oil spilled as a result of failure of the Gulf Oil pipeline do not result in a credible potential hazard to CPNPP. This conclusion and the ability of the retaining ponds to prevent crude oil liquid from reaching the SSI indicate that the Gulf Oil crude oil pipeline does not present a credible hazard to the CPNPP.

2.3 METEOROLOGY

2.3.1 REGIONAL METEOROLOGY

2.3.1.1 General Climate

The regional climatology of the site is described for the area bounded by 30 North, 100 West, 34 North, 96 West, shown in Figure 2.3-1. The Comanche Peak site is located approximately equidistant between Cleburne and Stephenville, Texas, west of the Brazos River. The site elevation is approximately 810 feet mean sea level (MSL). Over the region depicted in Figure 2.3-1, the terrain slopes gradually from 300 to 700 feet MSL in the southeast to 1,200 to 1,800 feet MSL in the northwest.

The climate of the region is continental and is characterized by rapid changes in temperature, marked extremes, and large daily and annual temperature ranges. The mean annual temperature decreases from southeast to northwest because of elevation and latitude changes. The general climate of the region is modified frequently by advancing warm moist air from the Gulf of Mexico, resulting in high humidities and cloudiness. Rainfall generally decreases from east to west and is heaviest in late spring and early summer.

In summer, the Bermuda High exerts a strong influence upon the weather of the region. It furnishes the tropical maritime air from the Gulf of Mexico which almost completely dominates the weather from May to September. This air mass is responsible for almost all of the thunderstorm activity in the region regardless of time of year. Occasionally, in summer, tropical continental air may move into West Texas from the high plateaus to the west. This air mass is characterized by very hot daytime temperatures and almost cloudless skies. Typically, summer has over 100 days with temperatures of 90°F or above and temperatures often exceed 100°F [1, 2, and 3]. Rainfall occurs during brief but sometimes intense showers and thunderstorms.

During the winter and early spring, outbreaks of polar continental air are the most common frontal activity. Although these fronts frequently have little weather associated with them, they often stall in Central and South Texas. Low ceiling and poor visibility may persist for three to four days or even longer over large areas [3]. On occasion, arctic air masses push through the region and cause some of the coldest temperatures. Cold spells, however, rarely last more than a few days. Normally, temperatures drop to 32°F or below about 30 days each year [1, 2]. Winter is the driest season, but one or two occurrences of snow and one or two occurrences of sleet or freezing rain may be expected in both January and February, the coldest months [3].

Pacific maritime cold fronts are more frequent in spring and fall than in winter or summer. These air masses usually bring clear skies to the region, although the weather along the leading edge of the front may be quite violent. Most of the dust storms of early spring and the violent thunderstorms during April, May, and June are associated with these frontal systems. Warm fronts are generally confined to the late fall and early spring months in this region. They are usually confined to the southern half of the region and move northward very slowly.

Spring is characterized by rapid changes of temperature, i.e., alternating periods of warm and cold conditions. On the average, thunderstorms are more frequent and more violent in the spring than any other season. Spring is normally the wettest season of the year. The fall is characterized by fair weather, low wind speeds, and moderate temperatures. It is the most pleasant season of the year.

Another major influence on the climate of this region is the so-called “dewpoint front,” which marks the westward extent of the moist air from the Gulf of Mexico. This trough of low pressure can exist at all times of the year. In summer, it marks the westward extension of the Bermuda High, while in winter it forms behind the migratory high moving across Central Texas following a cold front. The movement of this trough eastward results in a shift to west or southwest winds and dryer weather [3].

Annually, the prevailing surface winds in the region are from the south to southeast while the average wind speed is about 12 miles per hour (mph) [2]. In winter there is a secondary wind direction maximum from the north to northwest due to frequent outbreaks of polar air masses.

Annual average relative humidity is approximately 65 percent in the region while the mean percentage of possible sunshine is about 70 percent [1, 2].

Severe weather in the region is usually associated with heavy thunderstorms (including tornadoes) and tropical cyclones. Property damage occurs from flooding and high winds. Damaging hail also occurs in the site region.

The interplay between synoptic scale phenomena and topography is small in the region of interest. The effect of terrain features on synoptic scale flow can readily be ascertained when a larger area, which takes in the high country of West Texas and Eastern New Mexico, is included; i.e., the principal effect is that the high country forms a natural barrier to the flow of air. Consequently, moist tropical air from the Gulf of Mexico and air from the arctic or polar sources, which flows uninhibited through the site region, is effectively blocked from the areas to the west of the mountains. The net result is wide fluctuations in rainfall, humidities, and annual sunshine over the larger area.

2.3.1.2 Regional Meteorological Conditions for Design and Operating Bases

2.3.1.2.1 General

Meteorological data are presented in this section for severe weather phenomena such as hurricanes, tornadoes, thunderstorms, lightning, hail, high air pollution, and ice storms. Also presented are the meteorological data used for evaluating the performance of the ultimate heat sink and design basis tornado parameters.

2.3.1.2.2 Hurricanes

Tropical cyclones including hurricanes lose strength rapidly as they move inland, and the greatest concern is potential damage from winds or flooding due to excessive rainfall. The tropical cyclone season for Texas extends from June to October; storms are more frequent in August and September, and rarely occur after the first of October. The average frequency of tropical cyclones that affected Texas for the period 1931 to 1960 is approximately two per year; and of these about one in four were of hurricane force, i.e., winds greater than 74 mph [4].

The Probable Maximum Hurricane (PMH) is discussed in Section 2.4. For the Comanche Peak site, the PMH sustained (10-minute average) wind speed at 30 feet above ground is computed to be 81 mph [47].

2.3.1.2.3 Tornadoes

During the period 1955 through 1967, 58 tornadoes (4.46 mean annual frequency) occurred within a one-degree square centered near the Comanche Peak site [5]. It should be noted that statistical data on severe local storms, tornadoes particularly, are highly dependent on human observation. For example, as population density increases, the number of tornado occurrences observed and accurately reported generally increases.

The probability (P) of a tornado hitting a point in a given year is:

$$P = (2.8209 \times t)/A \qquad 2.3\text{-}1$$

where A is the area (in square miles) of a one-degree latitude-longitude square centered at the point, and t is the mean annual frequency [6]. The return period is the reciprocal of P. Table 2.3-1 summarizes the results for the site and nearby areas for the period 1955 through 1967. In the area north of about 31 North latitude, there is a greater frequency of large tornadoes with wide paths and long trajectories.

Based on the 13-year period of record from 1955 - 1967, the mean seasonal and annual number of tornado occurrences for Texas are [5]:

Winter	4.7	Summer	44.8
Spring	71.1	Autumn	23.7
	Annual	143.6	

During the period from 1968-1977 there were approximately 64 recorded tornado occurrences within about 40 miles of the plant site [40], but none of these occurrences were in Somervell County. Estimated characteristics of these tornados, expressed in terms of the Fujita- Pearson (FPP) tornado scale [4], are summarized below:

Scale No.	Maximum Windspeed[a]			Path Length		Path Width	
	F Scale (mph)	Expected Damage	No. of Occurrences	P Scale (miles)	No. of Occurrences	P Scale	No. of Occurrences
0	40-72	Light	12	<1.0[b]	33	<18 yd[b]	23
1	73-112	Moderate	34	1.0-3.1	9	18-55 yd	14
2	113-157	Considerable	14	3.2-9.9	8	56-175 yd	11
3	158-206	Severe	4	10-31	5	176-556 yd	5
4	207-260	Devastating	0	32-91	0	0.3-0.9 mile	0
5	261-318	Incredible	0	100-315	0	1.0-3.1 mile	1
				Unknown	9	Unknown	10

a) Subjective estimate based on observed damage given in the literature.

b) Tornados given in the literature as short and narrow are included in these categories.

For example, a tornado having a wind speed of 200 mph, a path length of 10 miles, and a path width of 100 yds would be expressed on the FPP scale as 3, 3, 2. The above data indicate that most of the tornados in this area have a path length of less than 20 miles, a path width of less than 180 yards, and a maximum wind speed of less than 160 mph.

The design basis tornado parameters used in the design and operation of CPNPP are listed below:

Translational Speed	60 mph
Rotational Speed	300 mph
Maximum Wind Speed (sum of the translational and rotational speed)	360 mph
Maximum Pressure Drop	3.0 psi
Rate of Pressure Drop	1.0 psi/sec

Compliance with Regulatory Guide 1.76 [7] is discussed in Appendix 1A(B). Tornado loadings are discussed in Section 3.3.2.

2.3.1.2.4 Thunderstorms

Thunderstorms, from which damaging local weather can develop (tornadoes, hail, high winds, and flooding), occur about 46 days each year based on Fort Worth data [8]. The maximum frequency of thunderstorms occurs from April to June, while months November through February have few thunderstorms. The monthly and seasonal distributions are displayed in Table 2.3-2.

2.3.1.2.5 Lightning

A typical thunderstorm is believed to produce one to three cloud-to-ground flashes each minute. The number of lightning strikes per square mile has been determined from photographs, records of strikes to power lines, and from electrical lightning counters. The combined results of several studies indicate that the number of flashes to ground per square mile per year is equal to between 0.05 to 0.8 times the number of thunderstorm days per year [9].

Applying these results to the thunderstorm data for Fort Worth in Table 2.3-2, the seasonal and annual estimates of lightning strikes are:

Winter	0.2 - 3.2	Summer	08 - 12.8
Spring	0.9 - 14.4	Autumn	0.4 - 6.4
	Annual	2.3 - 36.0	

Thus, the annual expectancy of lightning strikes for a square mile area in the site vicinity is between 2 and 36.

The expected probability of lightning strikes to the safety-related structures at the site on a seasonal and annual basis are presented in Table 2.3-2A. Included in this Table is the attractive area of each building and building dimensions used in the Table's development. The number of thunderstorm days for each season and annually, presented in Table 2.3-2, as well as the attractive area of each building, geographic latitude of the site and building dimensions were used in the development of Table 2.3-2A [42].

2.3.1.2.6 Hail

Almost all localities in Texas experience damage from hail. While the most commonly reported hailstones are 1/2 to 3/4 inch in diameter, hailstones 3 to 3-1/2 inches in diameter are reported in Texas several times a year.

During the period 1955 through 1967, there were 42 reports of large hail (3/4 inch diameter or larger) occurrences within a one-degree square centered near the Comanche Peak site [5]. This gives a mean annual frequency of 3.2 potentially damaging hailstorms per year for the entire one-degree square. Fortunately, recurrence of damaging hail at a specific location is very infrequent. The annual frequency of hail at Fort Worth is less than 0.05 percent of the hours observed [3].

The monthly and seasonal breakdown of large-hail occurrences (3/4 inch diameter or larger) for the state of Texas is given in Table 2.3-2 [5]. Damaging hailstorms are most frequent during April, May, and June, the period of severe-thunderstorm activity.

2.3.1.2.7 Air Pollution Potential

Conditions in the region generally favor turbulent mixing. Two conditions which reduce mixing, increasing the air pollution potential, are surface inversions and stable air layers aloft.

The surface inversion is generally a short-term effect and surface heating on most days creates a uniform mixing layer by mid-afternoon. On the other hand, if warming caused by subsiding air occurs, the second condition, namely a subsidence inversion, may result. Since both conditions usually occur in conjunction with light winds, the air pollution potential is amplified.

Holzworth [10] has computed mean morning and afternoon mixing depths and corresponding wind speeds for several stations in Texas. There is considerable variation in mixing depths among Texas stations; but the mixing depths all display similar seasonal variation, the depth being greatest during the warm months and shallowest during the cold months.

Since no data were presented by Holzworth for stations within the site region, data for Midland and San Antonio are presented in Table 2.3-3. Isopleths of the total number of forecast-days of high air pollution potential in five years are given in Figure 2.3-2. The data indicate that stable periods with light wind conditions are generally of short duration in the region.

Based on a 30-year period of record (1936-1965), Korshover [11] tabulated the number of times stagnating anticyclones persisted for four or more and seven or more days. Occurrences of stagnation were determined primarily on the basis of a surface pressure-gradient analysis. In the general area of the site, there were only three stagnation cases which persisted for at least four days during the 30-year period; the total number of stagnation days was 14. There were not any stagnation cases which persisted for seven or more days. The three stagnation cases which persisted for at least four days occurred during the fall.

2.3.1.2.8 Precipitation

Maximum rainfall, estimated by statistical analysis of regional precipitation data, is given in Table 2.3-4 for return periods of one to 100 years and for rainfall durations of from one-half hour to one day [12].

Probable maximum precipitation (PMP), sometimes called maximum possible precipitation, for a given area and duration is the depth which can be reached but not exceeded under known meteorological conditions. For the site area, the PMP for 6, 12, 24, and 48 hours is 25.5, 31.3, 34.7, and 39.1 inches, respectively [13]. These values are based on a 64 square-mile area.

The maximum recorded point rainfall for durations of 5 minutes to 24 hours at Abilene, Fort Worth, and Waco, are give in Table 2.3-5 [14].

On the other hand, drought conditions (extended periods of widespread meager precipitation) are known to occur in Texas. The most severe this century in Texas occurred during 1954-1956 (see Section 2.4.11). Fort Worth precipitation records, which illustrate the regional conditions, indicate that the average annual precipitation for this three-year period was 21.1 inches, with only 18.55 inches occurring in 1956 [15]. Although this period represents the worst drought in Texas, there have been three occurrences of annual precipitation less than 18.55 inches during the 81-year period from 1895 - 1975 at Fort Worth [8, 16]. The extreme minimum annual precipitation recorded, 17.91 inches, occurred in 1921.

Extreme snowfalls for representative stations in the area are given in Table 2.3-6 [17, 18].

Ice storms, precipitation in the form of freezing rain and/or sleet, occur occasionally in the region during the period December through March. The annual frequency of freezing rain at Carswell Air Force Base Fort Worth is only 0.3 percent of the hours observed, but the percentages for December, January, February, and March are 0.3, 2.5, 0.5, and 0.1 percent, respectively [3]. Moderate to heavy ice storms can be quite damaging to utility lines and trees as well as being a serious traffic hazard.

The worst ice storm on record in the Fort Worth-Dallas area occurred on January 6-9, 1937 [19]. As much as two inches of ice formed on wire and did not disappear until the 12th. Communications were disrupted and highway traffic was extremely hazardous. The estimated probability of ice thickness ≥ 2 inches occurring somewhere in North Texas, Arkansas, or Oklahoma in any one year is 0.06 [20].

The 100-year return period snow and ice pack for the area in which the plant is located, in terms of snow load on the ground and water equivalent, is listed below [21]:

Snow Load	= 7 lbs/ft^2
Water Equivalent	= 1.3 inches

The maximum 24-hour and seasonal snowfall recorded (1898-1970) in Fort Worth is 12 and 15.3 inches, respectively [18]. If the maximum seasonal snowfall (water equivalent of 1.5 inches) occurred in one storm on the 100-year return period snow and ice pack, the total water equivalent would be only 2.8 inches. In the period from 1970 - 1978, the maximum seasonal snowfall in Fort Worth was 17.6 inches (1977 - 1978 season). Even assuming the maximum winter snowfall occurred in one storm on top of an already present 100-year return period snowpack of 13 inches, the total weight would only be approximately 16 lbs/ft^2. This value is far below the design load on all nuclear safety-related buildings of an eight-inch maximum uniform depth of water (weight of about 42 lbs/ft^2) in addition to the regular live loads (see Section 2.4.1.1).

The 48-hour Probable Maximum Winter Precipitation (PMWP) for a 64 square-mile area is estimated to be 28.8 inches [13]. Because of the southern location of the site, almost all of this PMWP occurs as liquid. The roof drainage utilizes an exterior system, whereby the openings in the parapet walls are actually combined relief and drainage openings. These parapet walls relief openings insure that the eight-inch level is not exceeded during the PMP. They are specifically located at all roof low points and extend from the roof low point elevation to the top of the parapet (approximate height four feet). Their location is shown in Figure 1.2-2, 1.2-3, 1.2-5, 1.2-39 and 2.4-2. The length of an opening is six feet.

The size of these openings and their location preclude:

1. the possibility of ice and snow build-up blocking them and

2. roof ponding.

All design features of the relief and drainage opening are shown in Figure 2.4-42.

2.3.1.2.9 Dust Storms

Blowing dust or sand may occur occasionally in West Texas where strong winds are more frequent and vegetation is sparse. While blowing dust or sand may reduce visibility to less than five miles over an area of thousands of square miles, dust storms that reduce visibility to one mile or less are quite localized and depend on soil type, soil condition, and vegetation in the immediate area. At Fort Worth during the six year period from 1970-1975, only 0.02 percent of the observations had visibilities of one mile or less due to dust [22].

2.3.1.2.10 Ultimate Heat Sink

The performance of the ultimate heat sink is discussed in Section 9.2.5. The meteorological parameters used in the analysis are presented in Tables 2.3-7A, 2.3-7B and 2.3-7C.

Three meteorological records were examined in the analysis. These records are data from the onsite station and data from two offsite stations, Dallas-Fort Worth Regional Airport (DFW) and Waco Madison Cooper Airport. DFW is approximately 59 miles northeast of CPNPP, with a ground elevation of 551 ft. The DFW record available on magnetic tape begins with May 1953. Until the end of 1973, DFW observations were taken at Love Field. Waco is approximately 53 miles southeast, with ground elevation of 501 ft. The Waco record begins with July 1948. At the time of the analysis, data through December 1991 at both stations were available. The data consists of hourly (or three-hourly for the period 1965-1980) air and dew point temperatures, windspeed and direction, cloud cover and atmospheric pressure. In addition to these variables, surface heat exchange computations require solar radiation, which can be determined from cloud cover.

The onsite data set is not as complete as the offsite data. For this reason, no direct use of the onsite meteorological data set was made in the analysis. However, the 1974 onsite data set (Table 2.3-7A), previously identified as resulting in high Safe Shutdown Impoundment (SSI) temperatures for years preceding 1978, is presented here for comparison to the data sets selected from the offsite records for SSI performance analysis (Tables 2.3-7B and 7C). The day with the highest water temperature, as computed from the onsite meteorological record as a response to atmospheric heating or cooling, is July 15, 1974.

The two offsite records were used to compute SSI temperatures under normal operating conditions for comparison to SSI routinely monitored intake temperatures. These comparison showed that the DFW meteorological data more accurately represented onsite conditions than the Waco data. The DFW data were used for the SSI performance analysis.

The entire DFW record (39 years) was then used to compute fully-mixed water temperatures responding to atmospheric heating or cooling and steady heat load similar to those used in the SSI analysis. From this long record of response temperatures, 1-, 5-, 10-, 20-, and 30-day average response temperature were computed. Maximum values of these average temperatures were then identified and ranked by year. From this table, 1990 was identified as the year that would produce the highest temperatures in the SSI for all durations. The meteorological data from 1990 are shown in Table 2.3-7B for the period of maximum SSI temperatures. This period includes data for both for the 24 hour transient analysis and for the peak SSI intake temperature analysis. The day with the highest water temperatures computed from this meteorological record is August 31, 1990.

A similar search was conducted for the maximum 30-day evaporation. The fully-mixed computation was used to determine evaporation rates. The period of 30-day maximum evaporation was identified by examining the entire 39 year record using a moving sum procedure. The maximum natural evaporation occurred in 1980. The meteorological data for this period are shown in Table 2.3-7C. The 30-day period with the greatest potential for evaporation is June 25, 1980 to July 25, 1980. In order to be conservative, the evaporation analysis was continued for nine days beyond the 30 day minimum specified in R.G.1.27. The additional data are also shown in the Table.

2.3.1.2.11 Extreme Winds

Estimated extreme winds (fastest mile) for the general area based on the Frechet distribution are [24]:

Return Period (Years)	Wind Speed (Miles Per Hour)
2	51
10	61
50	71
100	76

Fastest mile winds are sustained winds, normalized to 30 feet above ground and include all meteorological phenomena except tornadoes.

Wind loadings for the site are discussed in Section 3.3.1.

2.3.2 LOCAL METEOROLOGY

2.3.2.1 Normal and Extreme Values of Meteorological Parameters

2.3.2.1.1 General

In this section, the normal and extreme statistics of wind, temperature, water vapor, precipitation, fog, and atmospheric stability are described. Long-term data from proximal weather stations (see Figure 2.3-3) have been used to supplement the shorter-term onsite data.

2.3.2.1.2 Surface Winds

Percentage frequencies of surface wind (wind roses) at Love Field, Dallas, for the years 1951-1960 are shown on an annual and monthly basis in Table 2.3-11 [25]. The symbol “+” indicates that the value is less than one-half of one percent but greater than zero. According to the annual table, surface wind directions at Dallas are from the southeast, south-southeast, and south 45 percent of the time. These directions predominate during the individual months also, but to a lesser extent during November through March. The annual average wind speed (not shown in Table 2.3-11) is 11.0 miles per hour. The maximum average wind speed occurs in the spring, while the minimum occurs in the fall.

Monthly and annual onsite wind frequency distributions at the 10-meter level are included in Table 2.3-27, presented in Section 2.3.3 [26]. Similar to the offsite distribution, the surface wind is from the southeast, south-southeast, and south 40 percent of the time. The annual average wind speed is lower onsite, averaging 8.5 miles per hour.

The “fastest mile” of record (long-term) at Fort Worth and Dallas for each month is presented in Table 2.3-12 [8, 27].

Frequency distributions of wind direction persistence, determined from observations at three-hour intervals over a five-year period (1969- 1973) from Fort Worth, Texas [28], are presented in Table 2.3-13. Persistence values are given for both one sector and three sectors (indicated by wind sector +22.5º in Table). Persistence was maintained through calm or missing observations if it was maintained subsequent to them. Because of these criteria, persistence as given by the number of consecutive three-hour observations tends to have a bias towards long durations.

Monthly and annual wind direction persistence, determined from hourly onsite observations at the 10-meter level [26] are presented in Table 2.3-14. These distributions, which are independent of stability, indicate that most cases of persistence are less than 12 hours in duration. During the four-year period of record, there were only eight cases of persistence greater than 24 hours, five of which occurred in the NNW sector. In the average wind speeds given in Table 2.3-14, 99.99 indicates that the wind speeds were invalid.

2.3.2.1.3 Temperatures

Monthly and annual values of daily mean temperature and average and extreme daily maximum and minimum temperatures are shown in Table 2.3-15, based on data records for Fort Worth [8]. From these data, the annual mean temperature in the site area is 66°F. The monthly averages indicate that July and August are the hottest months and January the coldest month.

The monthly and annual diurnal distributions of temperature at the site are shown in Table 2.3-16 [26]. Values of the mean, absolute maximum and minimum, and average daily maximum and minimum temperature for each month are also presented. The annual mean temperature from the onsite data is 17.1°C (63°F), which is some 3°F lower than the long-term mean as given by Fort Worth data.

Table 2.3-16 indicates that there were 93.8 percent valid primary ΔT measurements (10-60m) during the 4-year period of record (5/15/72 - 5/14/76). Table 2.3-23 shows that there were a total of 95.8 percent valid delta temperature (ΔT) measurements during the same 4-year period of record, including secondary ΔT measurements when primary ΔT measurements were invalid. Therefore, only two percent secondary ΔT measurements (10-30m) were substituted in the data record for invalid primary ΔT measurements.

In order to justify the direct substitution of secondary ΔT measurements during periods when the primary ΔT measurements were invalid, a simultaneous comparison of stability classes calculated from both ΔT measurements was made. Seven random days, encompassing all seasons, were selected from the 4-year period for the comparison. The comparison showed that there was a good correlation between the two ΔT samples with a higher frequency of both the most stable (F and G) and unstable (A and B) occurrences using the secondary ΔT measurements. Since the relative concentrations for CPNPP were calculated for an assumed

ground-level release, maximum relative concentrations (other conditions being equal), would occur during Pasquill G stabilities, the next highest relative concentrations would occur during Pasquill F stabilities, and so on. During the 7-day period of comparison, there were considerably more F and G occurrences for secondary ΔT measurements than for primary ΔT measurements. Therefore, substitution of secondary ΔT measurements during periods when primary ΔT measurements were invalid (two percent of the time) is quite conservative.

See Section 2.3.2.1.7 for more information on atmospheric stability.

2.3.2.1.4 Water Vapor

Monthly and annual average relative humidity for four different times of day are given in Table 2.3-17 from 10 years of record at the Fort Worth weather station [8]. Based on these data the annual average relative humidity is estimated to be about 68 percent. Monthly and annual average dewpoint temperatures and extreme maximum and minimum dewpoint temperatures are shown in Table 2.3-18, based on 1970-1975 data from Fort Worth [22].

The monthly and annual diurnal distributions of dewpoint temperature and relative humidity at the site are shown in Table 2.3-16, based on four years of onsite measurements [26]. Values of the mean, absolute maximum and minimum, and average daily maximum and minimum for both parameters are also presented. The annual average relative humidity is 63 percent, or five percent lower than the estimated long-term average at Fort Worth.

2.3.2.1.5 Precipitation

Monthly and annual precipitation normals and the mean number of days with precipitation equal to or greater than 0.10 and 0.50 inches, estimated for Comanche Peak by averaging data from Rainbow, Stephenville, Cleburne, Dublin, and Fort Worth are presented in Table 2.3-19 [15]. These data indicate that the highest monthly average rainfall occurs in May with an annual average of 31.3 inches in the area. The number of days with measurable precipitation ($\geq$ 0.01 inches) is also presented in Table 2.3-19 based on 1954-1973 data from Fort Worth [8]. Monthly precipitation extremes (maximum and minimum), presented in Table 2.3-20 for several stations in the area, indicate that the largest rainfalls occur during April and May [8, 15].

Snow and sleet occur from December through March with an occasional snow flurry in late November or early April. Monthly and annual average totals of snow and sleet from 20 years of record at Fort Worth [8] are shown in Table 2.3-19. These data give an annual expectancy of 2.9 inches of snow. Extremes of snowfall at selected stations in the area were previously presented in Table 2.3-5.

Monthly and annual precipitation wind roses are presented in Table 2.3-21. These data are based on four years of data at Fort Worth concurrent with the onsite data record [29]. These data show that of the 5.8 percent of the time that precipitation occurred, the maximum frequency of precipitation occurred with north winds. (Onsite data were not used because most of the hourly onsite precipitation data are invalid.)

2.3.2.1.6 Fog

Heavy fog is that which reduces visibility to one-quarter mile or less. Average monthly and annual number of heavy fog days based on 20 years of data at Fort Worth are presented in

Table 2.3-19 [8]. These data indicate that most of the heavy fog days occur in winter with a few occurrences during the remainder of the year.

2.3.2.1.7 Atmospheric Stability

Based on data for the period 1957-1971 at Fort Worth, the monthly and annual frequency distributions of stability classes are shown in Table 2.3-22 [30]. The stability classes are based on the Pasquill classification [31] and are defined in Table 2.3-22. These data indicate that the frequency of stable classes reaches a peak during the late summer and early fall.

Monthly summaries of the diurnal distribution of stability and stability persistence are presented in Table 2.3-23 for the onsite period of record [26]. Stability is determined from the 10-60 meter delta temperature measurements onsite and the class intervals specified in NRC Regulatory Guide 1.23 [32]. The annual percentages by stability class are as follows:

A	B	C	D	E	F	G
3.2	1.4	2.2	22.7	40.4	19.9	10.2

These frequencies are not directly comparable to the long-term frequencies at Fort Worth, since each distribution is based on a different criteria for determining Pasquill stability classes.

2.3.2.1.8 Mixing Heights

The frequencies of seasonal and annual mixing heights are included and discussed in Section 2.3.1.2.7. Since onsite measurements of mixing depth are neither required nor made, monthly mixing depths from upper air data at Carswell AFB, Fort Worth (5/72-10/73) and Stephenville, Texas (11/73-4/76), and surface observations from the National Weather Service (NWS) station in Fort Worth, concurrent with the onsite data record, are presented in Table 2.3.24 [33]. The method used for determining mixing depths is the same as described by Holzworth [10] with observations identified as P (precipitation), C (cold air advection), and M (missing) excluded from the record. Inclusion of P and C types would tend to increase the mean mixing depths given in Table 2.3-24.

2.3.2.1.9 Representativeness of the Onsite Data

To demonstrate that the onsite data sample is representative of a long term climatological average, concurrent data from Fort Worth (May 1972 through April 1976) were compared to a longer data record for Fort Worth (January through December, 1957-1971). The wind frequency distribution and the stability class frequency distribution and mean wind speeds are presented in Table 2.3-25.

Generally, the wind frequencies and stability distributions are in excellent agreement. The largest difference in wind frequency is only three percent and occurs in the south sector. One notable difference is the higher frequency of calms during the four-year period. The only significant differences in the stability class distributions occur in the “D” and “F” and “G” classes. For the four-year period, there are approximately five percent less “D” occurrences and five percent more “F” and “G” occurrences. The mean wind speeds are also in good agreement, averaging about one knot less during the four-year period.

Generally, the comparison implies that the Comanche Peak onsite data are representative of longer-term climatological conditions. The differences that do occur indicate that diffusion estimates will probably be higher than normal (conservative) for the four-year period of record.

2.3.2.2 Potential Influence of the Plant and Its Facilities on Local Meteorology

2.3.2.2.1 General

Potential modifications of the local meteorology at the site resulting from the construction and operation of the plant are believed to be small. The Reactor Complex is located approximately 450m west-northwest of the meteorological tower. The top of the dome is 69m above the level of the base of the meteorological tower. The Reactor Complex meets the requirements of the Standard Review Plan (46). Additionally wind was recorded from the west-northwest sector approximately 2.1% of all recordings; thus, any effect that the Reactor Complex does exhibit on our overall meteorological measurements program will be minimal. See Section 2.3.3.2 for a description of the Meteorological Instrumentation Building.

In addition, no other structures are in such proximity to the tower that will cause a significant alteration of the meteorological data. This is based upon the criteria that no structure equal to or greater than the height of a measuring level is closer than 10 times that measuring level to the tower, or that all sensors are at least 5 times the building height away from any building that is equal to or greater than the measuring levels.

The fill dirt pile located east-northeast of the meteorological towers is actually a mound of topsoil and will be distributed as required over the finish grade of the site. The topsoil mound is approximately 3000 feet from the primary meteorological tower location. Top of the pile is E1. 865'-9" approximate and the lower measure level on the tower E1. 870' approximate. Due to the linear distance away from the tower, and the relative height of the mound, the effects of the mound on meteorological measurements will be minimal. Additionally, wind was recorded from the ENE direction only 4% of all recorded winds (FSAR Table 2.3-21); therefore, for overall purposes, even if the topsoil mound did exhibit effects on measurements, the effect on cumulative total measurements would be minimal.

In sum, the Containment Building and associated facilities are expected to have some small influence on the local air flow; specifically, mechanical turbulence is expected downwind of the plant, due to building wake effects.

2.3.2.2.2 Impact of Squaw Creek Reservoir

Filling of Squaw Creek Reservoir commenced on February 15, 1977 with completion in May 1979. The potential impacts of the Squaw Creek Reservoir upon onsite meteorlogy are discussed in the Dames & Moore Report [34] which supports the conclusion that the reservoir will have a minimal effect upon local meteorology. Although no specific monitoring program is proposed to examine such effects, various meteorological measurements are sampled as discussed in 2.3.3.1.1.

The effects of the reservoir on wind speed, wind direction and vertical temperature gradient should be minimal. Small increases in the wind speed would be expected because the surface frictional coefficient of the air-water interface would be different from that which is now existent at elevation 770' MSL (reservoir elevation). Since Squaw Creek Reservoir has a maximum fetch of

about 4 1/2 miles, wind speeds may increase slightly for wind directions along the maximum fetch (southeast-northwest orientation). Small changes in the wind direction would also be expected due to variations of the surface frictional coefficient.

During winds from the northwest, northeast, and east-northeast, some modification of atmospheric conditions may occur: first as the trajectory moves over the reservoir surface, and subsequently as it returns to land, passes the tower and the reactor building, and then to the site boundary and some distance beyond. At all times with these wind directions the tower is likely to record higher wind speeds than prevail through the balance of a trajectory to the site boundary and beyond. As the trajectory returns to land, the reduction in wind speed due to the friction of land surfaces will be accompanied by increased turbulence. As a result of the offsetting process, the resultant dispersion values are not significantly altered.

On clear nights during light onshore winds from the above wind directions, the thermal stability of the air column may increase while the air column moves from the tower toward the site boundary and beyond. However, unless wind speeds are below about 3 mph, the overwater trajectory is not likely to have been of sufficient duration for significant modifications in its thermal stability to occur. In cases where the wind speed exceeds 3 mph, the tower will observe the air column stability near its overland equilibrium value and its readings will be representative of the thermal stability which will prevail throughout the trajectory to the site boundary and beyond.

With wind speeds of 3 mph or less in these directions, departures from overland stability values will be sensed at night by the tower, and the air column will move toward its more stable overland values during the trajectory from the reservoir shore to the site boundary and beyond. Conditions when the tower observed data may be somewhat unrepresentative and more favorable than the actual dispersion conditions downwind of the reactor building include the following:

1. When the wind direction is from the northwest, northeast, and east-northeast, and

2. The wind speed is 3 mph or less, and

3. Overland thermal stabilities have equilibrium values of Pasquill E, F, or G, and

4. During nighttime hours.

The onsite meteorological tower data for the 4-year period of record shows that conditions one through three occur concurrently only about 2.5 percent of the time. If daytime conditions were eliminated, the percentage would be somewhat smaller. By comparison, the combined frequency of occurrence of winds from these three directions is about 12 percent.

Thus, (1) 2.5 percent or less of the time, tower stability observations may be somewhat nonconservative when used to represent dispersion conditions at CPNPP, and (2) wind speeds may be higher than the representative overland values about 12 percent of the time, but downwind modifications to overland speeds are likely to be offset by compensatory increases in mechanically induced turbulence.

The effects of the reservoir on air temperatures in the area will be significant only when ventilation across the pond is at a minimum. The lack of ventilation would give air over the pond enough time to have its temperature measurably changed by the temperature of the surface

water for northwest or southeast winds. For low wind speeds, the maximum increase in air temperature would probably be large enough to have an effect upon thermal stability. It is estimated that the reservoir, due to heating of the air, would cause a decrease in the frequency of the more stable classifications and an increase in the frequency of the more unstable classifications. Thus, although overall changes are expected to be small, the Squaw Creek Reservoir should cause a slight improvement in diffusion meteorology due to enhanced ventilation and a reduction in the frequency of the very stable conditions.

Anticipated effects of the proposed Squaw Creek Reservoir on monthly average temperature, relative humidity, frequency of fogs for various visibility classes, and frequency of icing have been determined for the months of January and July (representing winter and summer conditions). Details of the methods used and the results are available in the Dames & Moore report [34] on the Squaw Creek Reservoir.

1. Temperature and Humidity Changes

   The night hours of both January and July experience the greatest modification in temperature and relative humidity. Largest modifications occur over the reservoir, with smaller effects over adjacent land area. The night hours of January and July show the greatest anticipated change of +1.2 degrees in temperature and the July nighttime hours have a 3.2 percent increase in relative humidity with 73 percent and 90 percent of the area affected, respectively. The daylight hours of July exhibit the smallest influence from the proposed reservoir.

2. Fogging - Frequency of Occurrence

   Conditional fog frequencies have been determined for various visibility classes for each of the following situations: (a) natural fogs unaffected by the reservoir, i.e., the baseline state, (b) natural fogs with visibilities altered by the reservoir, and (c) reservoir generated fogs.

   Natural fog (baseline) occurrences were determined from 3-hourly meteorological observations taken at the Dallas National Weather Service (NWS) station during the months of January and July over a 3-year period (1965-1967); occurrences were summarized by visibility classes. Natural fogs are not recorded by the NWS unless the visibility is seven miles or less. Onsite observations of fogs were not made.

   Data from the Dallas NWS station were selected to represent natural (baseline) fog occurrences at CPNPP on the basis of being the most representative data available. Fog occurrence at the Dallas NWS station is quite small [34]. Although these frequencies cannot be directly correlated to onsite fog frequencies, there are no known physical reasons that would contribute to markedly different baseline fog frequencies at CPNPP. The following meteorological characteristics are presented as evidence that baseline fog frequencies are similar or even less frequent onsite than at the Dallas NWS station:

   a. Pure radiation fog, which can be extremely localized, seldom occurs in the site area except for shallow patches [3].

b. Patchy or localized fog is more predominant, generally, in low lying area. Since CPNPP is located as much as 200 feet above adjacent terrain, baseline fog occurrences at the site should be less than at nearby low lying areas.

c. The site is not located adjacent to any major bodies of water (the Brazos River is over three miles away) that might increase local fog occurrences onsite.

d. Moisture levels decrease from East to West across much of Texas. Since CPNPP is located approximately 50 miles west of the Dallas NWS station, moisture conditions should be somewhat less favorable for fog formation onsite than at the Dallas NWS station.

Generally, except for July daylight hours, the presence of Squaw Creek Reservoir will decrease the visibility in naturally occurring fogs. In January, an increase of up to five percent is expected in the occurrence of fogs. July nighttime conditions show the least influence of the reservoir, with no change in the frequency of fog occurrence. During July daylight hours, a decrease of up to one percent in the occurrence of fog is expected.

3. Fogging - Visibility of One Mile or Less

Fog with visibility of one mile or less may be frequent enough to limit activities in the area. Daylight hours show the greatest increase of fog frequencies in this range of visibilities, +5 percent, and the largest area modified. During January daylight hours, the study also shows that Highway 144, East of the reservoir, should experience a three percent increase in occurrence of visibility restricted to one mile. Road 201, west of Squaw Creek Reservoir, should experience a one percent increase of fog visibility less than or equal to one mile. Highway 144 is expected to have an increase of one to two percent in fog frequency with visibility less than or equal to one mile during the night hours of January. This fog will extend for about 1.7 miles on the southeast side of the reservoir.

July daylight hours, for this visibility range, are expected to have a two percent increase in the maximum frequency of fogs. A one percent increase over natural fog frequencies is expected along Highway 144 north of the reservoir and along Roads 201, 204, and 51, west of Squaw Creek Reservoir. No modification is anticipated for the July night hours in this visibility class.

4. Icing

Potential icing conditions are specified by the occurrence of reservoir produced fog accompanied by subfreezing temperature. January night hours are anticipated to have a maximum of one percent increase in the frequency of icing. These conditions occur over or near the reservoir, and therefore have little effect on the area.

2.3.2.2.3 Topographical Description

A map of the Comanche Peak area for a distance of five miles from the site is shown in Figure 2.3-4. The eight radial lines correspond to the eight individual topographic cross-sections which appear in Figure 2.3-5 through 2.3-8. These figures indicate the maximum elevation versus distance from the plant in each sector. The site elevation is approximately 810 feet MSL.

The terrain varies from 600 to 1,000 feet MSL within five miles of the site, and is generally in this range out to 50 miles. General topographic features for a radius of fifty miles are shown in Figure 2.3-9.

Variable terrain has a potential to influence local diffusion characteristics. Terrain variations on the order of plus or minus 200 feet are not pronounced enough to cause any significant flow blocking. Two possible influences, though, cold air drainage and channeling, have been investigated. The occurrences of cold (more dense) air drainage down Squaw Creek was assessed by a comparison of wind direction frequencies between the 10-meter (850 ft. MSL) and 60-meter (1000 ft. MSL) levels (Figure 2.3-10) for a 131-day period. If drainage occurs, then marked increases of down-valley wind frequencies (ESE and SE) from the upper to the lower level would be expected. Marked changes in frequency do not appear in the data; therefore, it is concluded that cold air drainage along Squaw Creek is not significant. Though not significant, the occurrence of cold air drainage cannot be completely ruled out on the basis of a comparison of wind directions measured at approximately 850 and 1000 ft. MSL, since the Squaw Creek drainage basin lies below 700 ft. MSL. However, the Squaw Creek Reservoir has been filled since this comparison was made (see Section 2.3.2.2.2). This effectively modifies the topography over a large area surrounding CPNPP to a minimum elevation of 770 ft. MSL, or only about 40 feet less than site elevation. Thus, cold air drainage is unlikely.

Channeling of air flow, the other potential topographical effect, was studied by comparing 10-meter wind directions with nearby wind direction data from Dallas Love Field, where surroundings are relatively flat. A significant increase in wind direction frequencies for both up and down valley sectors (WNW, NW, NNW, ESE, and SE) should occur if channeling is an important influence. Approximately eight months of concurrent wind direction data, shown in Figure 2.3-11, indicate that channeling of the air along Squaw Creek is not a prominent effect.

The channeling and air-drainage study results are indicative of a relatively flat terrain. There is even less topographical variation after creation of the reservoir. This implies that there is less topographic effect on the local airflow and, therefore, a slight improvement in diffusion meteorology. In conclusion, the onsite data collected prior to, and after, the creation of the reservoir does not change appreciably.

2.3.2.3 Local Meteorological Conditions for Design and Operating Bases

Local meteorological data have not been used for design and operating basis considerations other than those conditions referred to in Sections 2.3.4 and 2.3.5. Design wind loadings, tornado loadings, and snow loadings are referred to under Regional Meteorology, Section 2.3.1.

2.3.3 ONSITE METEOROLOGICAL MEASUREMENTS PROGRAM

2.3.3.1 Pre-Operational Program

The pre-operational onsite meteorological program is designed to measure the parameters needed to evaluate the dispersive characteristics of the site for both the routine operational and the hypothetical accidental releases of radionuclides to the atmosphere.

2.3.3.1.1 Instrumentation and Recording Systems

The majority of the measurements are made on a 200-foot steel-framed tower which is located 1,500 feet east of the reactor complex (See Figure 2.3-12). The location of the tower in relation to the entire site area is shown in Figure 2.1-2. The terrain surrounding the tower is relatively hilly and is covered by widely scattered scrub brush, small mesquite, and cedar.

The following measurements are sampled on the tower:

1. Wind speed at two levels (10 and 60 meters)

2. Wind direction at two levels (10 and 60 meters)

3. Ambient temperature at three levels (10, 30, and 60 meters)

4. Ambient dewpoint temperature at two levels (10 and 60 meters)

5. Thermal stability, for two height intervals (10 to 30 meters, and 10 to 60 meters)

6. Wind direction variability (10 meters)

In addition to these measurements, precipitation and solar radiation (both total and net) are sampled near the base of the tower.

Descriptions of the instruments employed in these measurements are found in Tables 2.3-26.

To assure a high percentage of data recovery, duplicate recording systems are used. All variables are recorded in analog form on strip charts which record continuously, and digitally on magnetic tape which records ”one scan each minute.” The latter is the most common method of complying with criteria in Reg. Guide 1.23 for digital recording systems; that is, to record instantaneous values of each meteorological parameter once each minute. If the total number of minute observations during the hour for any parameter is less than 15, then that parameter is considered to be invalid for that hour. The magnetic tape is the primary recording system.

A comparison of analog and digital hourly average values was made to support the use of instantaneous values recorded once each minute to represent hourly average conditions. Comparisons of both wind speed and direction at the 10-meter level for a randomly selected 2-week period are summarized in Table 2.3-35. These data indicate overall agreement between the hourly average values from the analog and digital recording systems.

The digital recording system reduces each sensor output signal to a digital voltage form, with a range of 0 to 999 millivolts (mv) (except delta T, with a range of -999 to 999 mv), and records all variables on magnetic tape once per minute.

Data lost during outages or malfunctions of the digital recorder are reduced manually from the strip chart record. The hourly averages are logged for insertion into the meteorological record.

2.3.3.1.2 Maintenance and Calibration

To assure data quality and accuracy, a comprehensive calibration of the meteorological station components is performed at six month intervals. The procedure includes close visual inspection of all instrument sensors for wear, electronic component calibration, ambient temperature, and dewpoint comparison using mercury-type thermometers, and calibration of recorders.

Normal maintenance includes a comprehensive inspection of the station's electronic and mechanical equipment as part of an ongoing operation and maintenance program. Inspections are performed on a weekly frequency, as a minimum, but on average two operational inspections are performed per week. Station operating procedures call for, among other things, a manual check of the zero and full-scale positioning of the analog recorders, as well as a verification of the associated DC voltages displayed by the digital panel meter for the primary recording system.

The calibration and maintenance program is accomplished through the effort of experienced CPNPP technicians.

Pre-operational data recovery and analysis was initiated on May 15, 1972. For the four year period ending May 14, 1976, about 96 percent recovery of primary variables (wind speed, wind direction, and delta temperature) was accomplished.

2.3.3.1.3 Data Processing

With the exception of precipitation and wind direction, hourly averages of the digital minute-by-minute observations are calculated from the following scalar equation:

$$\bar{B}_j = \frac{r_j}{n} \sum_{i=1}^{n} B_{ji} \qquad 2.3\text{-}2$$

where

B_j = the average hourly value for the j^{th} variable (engineering units)

n = the total number of minute observations during the hour normally 60, but if n <15, data for that hour are considered to be missing)

B_{ji} = the i^{th} minute observation of the j^{th} variable (millivolts)

r_j = the conversion factor to change the j^{th} variable into engineering units

Whereas most of the averages are scalar inform, the average wind directions are determined by the following averaging technique:

Each minute observation of wind vector (speed and direction) is broken into its components, u and v, according to

$$u_i = S_i \times \sin(\theta i - \pi)$$
$$v_i = S_i \times \cos(\theta i - \pi) \qquad \text{2.3-3}$$

where

u_i = the east-west component of wind for the minute

v_i = the north-south component of wind for the minute

S_i = the scaler wind speed for the minute

θi = the wind direction for the minute

The u_i and v_i are added separately and the sums are divided by the total number of minute observations for the hour to establish the average components, u and v, i.e.:

$$\bar{u} = \frac{1}{n}\sum_{i=1}^{n} u_i \qquad \text{2.3-4}$$

$$\bar{v} = \frac{1}{n}\sum_{i=1}^{n} v_i$$

where

$\bar{u}$ = the average east-west component of wind for the hour

$\bar{v}$ = The average north-south component of wind for the hour

n = the number of valid minute observations for the hour

The average wind direction is found by converting the average components into a vector direction, i.e.,

$$\bar{\theta} = \tan^{-1}(\bar{u}/\bar{v} + \pi) \qquad \text{2.3-5}$$

where

$\bar{\theta}$ = the average vector wind direction during the hour

The precipitation accumulated during the hour is established by subtracting the amount of precipitation measured by the rain gauge at the beginning of the hour from the amount measured at the end of the hour.

Data analysis for both wind distribution and diffusion characteristics of the site require three basic atmospheric variables. These three variables together with the primary and secondary (back-up) measurements for each are as follows:

Horizontal wind speed:	primary, 10-meter level secondary, 60-meter level
Horizontal wind direction:	primary, 10-meter level secondary, 60-meter level
Delta temperature (ΔT)	primary T, 10 to 60 meters secondary T, 10 to 60 meters

The secondary measurement is needed only during periods of outage of the primary system, and is reduced to the appropriate level as follows: wind speed at 60 meters is converted to wind speed at 10 meters using the power law [35]:

$$V_{10} = V_{60}\left(\frac{10}{60}\right)^{S} \qquad 2.3\text{-}6$$

where

V_{10} = wind speed at 10 meters

V_{60} = wind speed at 60 meters

S = .26 for Pasquill classes A, B, C, and D or .50 for Pasquill classes E, F, and G

Wind direction at 60 meters is directly substituted for wind direction at 10 meters.

ΔT (redundant) between 10 and 60 meters is substituted for ΔT between 10 and 60 meters, as required, for classification of atmospheric stability in accordance with Table 2 of Regulatory Guide 1.23.

The final step in the data reduction program is the listing, in sequential order, of the concurrent, hourly-averaged values of the weather elements observed at the site. The data record provides the input data for all types of meteorological analyses needed to define the site atmospheric dispersive qualities. The hourly onsite data record used in the Section 2.3 analyses will be provided to the NRC separately from this report.

2.3.3.2 Operational Program

Prior to fuel load of Unit One, the meteorological measurements program of the Comanche Peak Nuclear Power Plant shall consist of the following:

1. A primary meteorological measurements program.

2. A backup meteorological measurements system.

3. A system for making near real-time predictions of the atmospheric effluent transport and diffusion.

4. A capability for remote interrogation, on demand, of the atmospheric measurements and prediction systems by the licensee, emergency response organizations, and the NRC Staff.

To accomplish these goals, “the pre-operational meteorological instrument system” has been modified. The current “operational meteorological measurements system” transmits the above mentioned meteorological parameters to a multi-channel digital recorder, METSYS Computer and the plant computer.

The operational program consists of a 60m multi-level primary meteorological tower located at plant grid coordinates N9519.44 ft. by E12111.75 ft. (el. 838 ft. - 9 in.) which is east of the Unit 1 and Unit 2 reactor buildings. The primary meteorological tower directly monitors or provides information to determine the following meteorological parameters:

- Wind speed at 10m and 60m;

- Wind direction at 10m and 60m;

- Ambient temperature at 10m;

- Delta-temperature between 10m and 60m (redundant channels at each level);

- Sigma theta at 10m;

- Precipitation near ground-level.

The primary tower is a 60m, guyed, open lattice type tower with an instrument elevator and instrumentation booms located at the 10m and 60m levels. These booms are oriented to the west. The aspirated temperature shields at 10m and 60m are oriented laterally to the north. The primary and backup tower instrument translators are located in an environmentally controlled building which is approximately 70 ft. West-Northwest of the primary tower.

The Meteorological Instrumentation Building was constructed near the base of the tower to support both primary and backup tower field instruments. It is 12 ft. wide by 16 ft. long by 9 ft. high with a steel floor and galvanized steel siding, roof and ceiling on a concrete slab. Environmental control in the summer is maintained by an air conditioning unit. In winter, environmental control is maintained by an electric heating system. The heating/AC unit is controlled by an automatic thermostat.

The operational program also consists of a separate 10m backup meteorological tower located approximately 75 ft. East-Northeast from the 60m primary tower. The backup tower monitors or determines the following parameters:

- Wind speed at 10m;
- Wind direction at 10m;
- Temperature at 10m;
- Sigma theta at 10m

The backup tower is a 10m free standing open lattice type tower with an instrumentation boom located on top of the tower at 10m. The aspirated temperature shield is orientated laterally to the north to further minimize the effects of direct sunlight on the measured temperature.

To ensure that meteorological data being collected by the backup tower at its location near the primary tower was representative of coincident data being recorded at the 10 meter level of the primary tower, a real-time data analysis consisting of a 3-month time period was performed. The real-time representativeness analysis consisted of statistical correlations for coincident wind speed, wind direction, and sigma-theta parameters from the two towers for the minimum time period specified above. The results of this analysis was used to demonstrate that meteorological data from the backup tower can be reliably substituted during loss-of-data periods from the primary tower.

The recording of meteorological data from both the primary and backup towers is accomplished by utilizing one digital and one auxiliary analog system. The recorder system is a digital paperless recorder on the meteorological instrument panel in the Control Room. All meteorological parameters from the primary tower, and wind speed, wind direction and sigma theta from the backup tower, are displayed on this recorder.

To ensure an acceptable data recovery of the precipitation measurements for the operational program, equipment was procured and is maintained to assure at least 90% annual data recovery. The primary system for recording precipitation data is checked at least once per week to assure its continued function.

Meteorological data from both towers is provided to the Met and plant computers. Signals from both meteorological towers are transmitted through shielded twisted pair cable to the digital to analog converter of the meteorological system receiver located in the Unit 1 Plant Computer Room.

Digital output of the Met and plant computers are located in the Unit 1 Plant Computer and Control Room. Digital output of the plant computers are also located in the Technical Support Center (TSC) and Emergency Operation Facility (EOF), where meteorological data consistent with the requirements of NUREG-0696 (45) are displayed.

The Met computer is designed to provide digital readout of meteorological data received from the primary and backup towers for all parameters. Both 15-minute and hourly-averaged data are generated. The 15-minute averaged data are derived from the meteorological parameters that are sampled every five seconds (except precipitation which is a totalized value). The hourly

averaged data are derived from the 15-minute averages. The 15-minute averaged data and the hourly-averaged data can be stored internally in the computer for a period of up to 10-years. The methodology for meteorological data processing as described in Section 2.3.3.1 was used on the meteorological data collected during the pre-operational monitoring program and for the data initially collected under the approved CPNPP operational meteorological monitoring program. The data averaging methodology has been updated with the installation of the Met computer. This updated data averaging methodology continues to meet the requirements of Regulatory Guide 1.23.

The plant computer is designed to provide digital readout of 15-minute averaged data from the primary meteorological tower. The 15-minute averaged data are based on a 5-second sampling rate. Trending data for the previous week are also available from the plant computer.

The following table shows the sampling time, averaging time and number of samples per averaging period for both the Met and plant computers:

Computer	Sampling Time (sec)	Averaging Time (min)	Number of Samples Per Averaging Period
Met	5	15	180
Met	(a)	60	(a)
Plant computer	5	15	180

a) The hourly average is derived from the 15-minute averages.

The operational program will be conducted in accordance with the requirements specified in Regulatory Guides 1.21 and 4.1 (36, 37), Second Proposed Revision 1 to Regulatory Guide 1.23 (44), and Revision 1 to NUREG-0654 (43). Descriptions of the instruments employed in the Operational meteorological measurements program are found in Table 2.3-34. Tables 2.3-34A and 2.3-34B provide information about meteorological instrumentation system accuracy.

2.3.3.3 Wind Roses By Pasquill Stability Classes

Monthly and annual wind roses for each Pasquill stability class (and all classes combined) for the four-year period of record onsite are shown in Table 2.3-27 [26]. These tables are based on wind distributions at the 10-meter level and the 10-60 meter ΔT measurements. During periods of outage of the primary variables, secondary wind and ΔT measurements were used as discussed in Section 2.3.3.1.3.

A discussion of the representativeness of the onsite data is provided in Section 2.3.2.1.9.

2.3.4 SHORT-TERM (ACCIDENT) DIFFUSION ESTIMATES

2.3.4.1 Objective

The onsite meteorological data record at the Comanche Peak site for the period May 15, 1972, through May 14, 1976, has been used to calculate dilution factors which can be anticipated in the event of an accidental release of radionuclides into the atmosphere. The one-hour dilution factors are calculated at the site boundary (exclusion area); for longer time periods the factors are calculated at the outer boundary of the low population zone (LPZ).

2.3.4.2 Calculations

Diffusion calculations for accidental or short-term releases of radionuclides were initially performed in accordance with the criteria provided in Regulatory Guide 1.4 [38]. Short term diffusion estimates were subsequently recalculated to incorporate the modeling features of NRC Draft Regulatory Guide 1.XXX [48]. It was assumed that the releases emanate from a point source at ground level; i.e., no advantage is realized from effluent emissions from elevated release points. During downwind transport, the effluent plume is assumed to spread according to a Gaussian dispersion model.

2.3.4.2.1 The Diffusion Model for Two Hours or Less

The analytical procedure for evaluating the 0-2 hour accident period is based on a revision of the model described in NRC Regulatory Guide 1.4; the revision incorporates the modeling features of NRC Draft Reg. Guide 1.XXX [48]. The changes reflect variations in atmospheric diffusion factors that occur as a function of wind direction and varying site boundary distance. Allowances are made for meandering plumes during light winds and stable atmospheric conditions. The model is distance and direction-dependent. The hourly χ/Q values used to represent the 0-2 hour accident period were determined in the following manner.

During neutral and stable conditions when the wind speed at the lower level is less than 6 meters per second (mps) the relative concentration is computed as:

$$\frac{\chi}{Q} = \frac{1}{\bar{u} \quad \pi\Sigma_y\sigma z} \qquad 2.3\text{-}7$$

provided it is less than the greater value calculated from either

$$\frac{\chi}{Q} = \frac{1}{\bar{u}(\pi\sigma_y\sigma_z + cA)} \qquad 2.3\text{-}8$$

or

$$\frac{\chi}{Q} = \frac{1}{\bar{u}(3\pi\sigma_y\sigma_z)} \qquad 2.3\text{-}9$$

where,

χ/Q = relative concentration at ground level (s/m^3)

$\bar{u}$ = hourly average wind speed at 10 m level (mps)

Σ_y = lateral plume spread (m) (a function of atmospheric stability, wind speed, and downwind distance from the release). For distances up to 800 meters, $\Sigma_y = M\sigma_y$; where M is a function of atmospheric stability and wind speed. For distances greater than 800 meters,

$$\Sigma_y = (M-1)\sigma_y(@800m) + \sigma_y$$

A = minimum cross-sectional area of the reactor containment structure (3200 m^2) assuming that:
width of containment building = 140 feet
height of spring line above grade = 190.5 feet
radius of dome circle = 70 feet

c = building shape factor (taken as 0.5)

σ_y = lateral plume spread (m) at a given distance and stability

σ_z = vertical plume spread (m) at a given distance and stability.

During all other atmospheric stability and/or wind speed conditions, χ/Q is the greater value calculated from Equations 2.3-8 and 2.3-9.

Plume meander was accounted for by modifying the lateral diffusivity, σ_y. The meander function (M) is evaluated as follows:

For Pasquill stabilities A-C at all wind speeds or all stabilities when wind speed > 6 mps; M = 1. For wind speed ≤2 mps;

Stab D; M = 2

Stab E; M = 3

Stab F; M = 4

Stab G; M = 6

For wind speed between 2 and 6 mps, M is evaluated by a curve fitting technique and multiplied by σ_y.

The direction dependent 5- and 50-percentile χ/Q's by sector were calculated by the following procedure. The 5- and 50-percentile values were determined by normalizing the frequency of wind into the sector of interest. The 5-percentile χ/Q value is the point in a given sector χ/Q

cumulative frequency distribution which is equalled or exceeded (5 x 6.25/f) percent of the time, where f is the frequency in percent of winds in the sector. Similary, the 50-percentile value is the point in a given sector χ/Q cumulative frequency distribution which is equalled or exceeded (50 x 6.25/f) percent of the time. Calm conditions were included in the calculations by setting the wind speed to the threshold value of the wind direction sensor (0.75 mph) and distributing them among the 16 direction sectors in proportion to the directional frequencies in each stability class of wind speeds of 2 mph or less. This is a slightly larger speed class interval than the 1.5 mph limit recommended by Reg. Guide 1.XXX [48], but is justified due to the relatively small number of observations in the lowest wind speed class (≤1 mph) at CPNPP.

2.3.4.2.2 Estimated Values of One-Hour Dilution Factors

The minimum Exclusion Area Boundary (EAB) distances in each sector are presented in Table 2.3-28. For each wind direction sector, the minimum EAB distance was assumed to be the minimum distance within a 45 degree direction sector, centered on the direction sector of interest. See Section 2.1.2 for a discussion of the exclusion area boundary parameters.

The highest 5-percentile concentration in any sector is 1.6×10^{-4} s/m^3 and occurs northwest of the plant. This maximum χ/Q was calculated at a distance of 2080m although the actual minimum EAB distance in the NW sector is 2106m. This is conservative. The highest 50-percentile concentration is 4.5×10^{-5} s/m^3 and occurs north-northwest of the plant.

2.3.4.2.3 Diffusion Estimates for Periods Greater Than Two Hours

Determination of χ/Q's for time periods of 0-8 hours, 8-24 hours, 1-4 days, and 4-30 days was accomplished by graphical interpolation between 2-hour χ/Q's in each sector and the annual average χ/Q's in each sector, both at the LPZ distance (4 miles). Hourly 5- and 50-percentile χ/Q's for each sector were computed at the LPZ using the same technique as described above for the 5- and 50-percentile χ/Q's by sector at the EAB (hourly χ/Q's were used to represent the 0-2 hour χ/Q's). The annual average χ/Q's used in the graphical interpolation are those given in Table 2.3-33 at the LPZ distance of 4 miles. For each sector, the hourly 5-percentile χ/Q's and the annual average χ/Q's, both at the distance of the LPZ, were plotted on a log-log coordinate graph with ordinate values representing χ/Q and abscissa values being hours.

These two points, (χ/Q_1, 2 hours) and (χ/Q annual, 8760 hours) were connected by a straight line and values of χ/Q for periods of 8, 16, 72 and 624 hours were extracted. These χ/Q's represent the 0-8 hour, 8-24 hour, 1-4 day, and the 4-30 day accident period 5-percentile χ/Q's per sector at the LPZ distance. Similar graphical interpolation was used to determine 50-percentile χ/Q's for each accident period.

The 5- and 50-percentile χ/Q's for each accident period at the LPZ are given in Tables 2.3-37 and 2.3-38 for each of the 16 meteorological sectors.

2.3.4.2.4 Representativeness and Topographic Effects

As discussed in Section 2.3.2.1.9, the onsite data sample was considered to be conservatively representative of meteorological conditions at the site. The notable differences observed during the onsite period of record were a higher frequency of calm wind speeds and a higher frequency

of stable conditions. These conditions have undoubtedly increased the magnitude of the χ/Q values given in Section 2.3.4 above those to be expected over a longer climatological interval.

Topographic effects at the site were discussed in Section 2.3.2.2.3. The results were indicative of a flat terrain with no appreciable effects on short-term diffusion estimates. After creation of the Squaw Creek Reservoir, a slight improvement is expected in diffusion meteorology due to both reduced topographic variation and the ameliorative effects of a heated reservoir on the frequency of very stable conditions.

2.3.5 LONG-TERM (ROUTINE) DIFFUSION ESTIMATES

2.3.5.1 Objective

The onsite meteorological record (5/15/72 to 5/14/76) is used to provide realistic estimates of annual average atmospheric dilution factors to a distance of 50 miles from the plant for use in calculating the dispersion through air pathways of radionuclides released in routine plant operations. As indicated in Section 2.3.3, the hourly onsite data record will be provided to the NRC separately from this report.

2.3.5.2 Calculations

The average annual dilution factors which are applicable to routine venting or other routine gaseous-effluent releases have been evaluated from the data record using the technique presented in Regulatory Guide 1.111 [39]. The equation used is a sector-spread equation, namely:

$$\chi/Q\ (i, D) = \frac{T}{mBD}\ \frac{\sqrt{2}}{\sqrt{n}}\ \sum_{1}^{n}\ \frac{1}{\overline{u}\ (i)\ (\sigma_z^{\,2}(p, D) + cV^2/\pi)^{1/2}} \qquad 2.3\text{-}10$$

where,

$\chi/Q(i,D)$	=	dilution factor (seconds/meter^3) at distance D, in affected direction Sector i
m	=	number of valid hourly observations in the data record
n	=	number of occurrences in the data record affecting direction Sector i
i	=	wind direction Sector index
p	=	Pasquill stability class index
$\sigma_z(p,D)$	=	hourly average vertical dispersion coefficient of the plume (meters) for a given Pasquill class, at distance D
c	=	building wake shape factor (taken as 0.5)

V	=	vertical height of the reactor containment structure (79.4 meters)
B	=	horizontal plume spread factor (taken as $\pi/8$ radians)
$\bar{u}(i)$	=	hourly average wind speed (meters/second) affecting direction Sector i
D	=	distance from reactor containment structure
T	=	terrain correction factor; open terrain, valley flow, or other factor for χ/Q adjustment (distance dependent)

The wake factor (cV^2/π) influence is limited such that the resultant χ/Q may not be reduced greater than a factor of $\sqrt{3}$, i.e., [π/Q] wake $\geq$ [$1/\sqrt{3}(\chi/Q)$ no wake]. Calm conditions are included in the calculations by setting the wind speed to one-half the threshold value of the speed or direction sensor and distributing them among the 16 direction sectors in proportion to the directional frequencies of the one and two mph speed class intervals in the appropriate stability class.

Equation 2.3-10 is the straight-line trajectory model defined in NRC Regulatory Guide 1.111 assuming a ground-level release mode; that is, the release occurs at an elevation less than or equal to the adjacent building height. Since the site is basically in open terrain with gently rolling hills, the T factor in Equation 2.3-10 is the open terrain correction factor given in Reg. Guide 1.111[39].

Annual average dilution factors to a distance of 50 miles from the plant are shown in Table 2.3-33. The maximum value at the actual EAB is 3.3×10^{-6} seconds/meter^3 and occurs north-northwest of the plant at a distance of 1.29 miles. There are no higher values beyond the site boundary since for ground level releases concentrations monontonically decrease from the release point to all locations downwind.

Long-term dilution factor estimates for distances out to five miles are displayed in Figure 2.3-18. Estimates out to 50 miles are illustrated in Figure 2.3-19.

The annual average dilution factors given in this section are likely to be quite conservative for the reasons given in Section 2.3.4.2.4.

46. “Onsite Meteorological Measurements Programs,” Section 2.3.3, “Standard Review Plan for the Review of Safety Analysis Reports for Nuclear Power Plants,” LWR Edition, NUREG-0800, Rev. 1, May, 1978.

47. “Meteorological Characteristics of the Probable Maximum Hurricane, Atlantic and Gulf Coasts of the United States,” HUR 7-97, U.S. Department of Commerce, May 1968.

48. “Atmospheric Dispersion Models for Potential Accident Consequence Assessments at Nuclear Power Plants,” Draft Regulatory Guide 1.XXX, September 23, 1977.

TABLE 2.3-1
TORNADO POINT PROBABILITY WITHIN A GIVEN YEAR AT SELECTED LOCATIONS (1955-1967)[a]

Square Location	Significance	Annual Frequency, $\dot{t}$	Probability P	Return Period (Years)
Plant Site		4.46	0.00313	320
Adjacent (East)	Area Comparison	3.54	0.00248	403
Adjacent (South)	Area Comparison	3.23	0.00241	415
Adjacent (West)	Area Comparison	2.08	0.00146	685
Adjacent (Northwest)	Maximum in Texas	5.23	0.00371	269
North of Oklahoma City	Maximum in U.S.	8.00	0.00588	170

a) Period of record is in parentheses on this and succeeding tables when applicable.

TABLE 2.3-2
AVERAGE NUMBER OF THUNDERSTORM DAYS[a] AND LARGE-HAIL[b] DAYS

Period	Thunderstorms Fort Worth (1954-1973)	Large Hail Texas (1955-1967)
January	1	<1/2
February	2	2
March	4	7
April	7	25
May	7	30
June	6	18
July	5	4
August	5	1
September	4	2
October	3	3
November	2	1
December	1	<1/2
Winter	4	2
Spring	18	62
Summer	16	23
Autumn	9	6
Annual	46	93

a) Defined as day on which thunder is heard at station.

b) 3/4-inch diameter and larger.

TABLE 2.3-2A
SEASONAL AND ANNUAL ESTIMATES OF LIGHTNING STRIKES TO SAFETY-RELATED STRUCTURES

Name of Safety-Related Structure	Winter	Spring	Summer	Autumn	Annual
Auxiliary Building	0.019	0.084	0.074	0.042	0.214
Reactor Building (Each Unit)	0.074	0.332	0.295	0.166	0.848
Electrical and Control Building	0.011	0.051	0.046	0.026	0.131
Safeguards Building (Each Unit)	0.018	0.079	0.071	0.040	0.203
Diesel Building (Each Unit)	0.007	0.030	0.027	0.015	0.077
Fuel Building	0.018	0.082	0.073	0.041	0.209
Service Water Intake Structure	0.002	0.010	0.009	0.005	0.024
Condensate Storage Tank	0.003	0.015	0.014	0.008	0.039
Reactor Makeup Water Storage Tank	0.002	0.007	0.007	0.004	0.019
Refueling Water Storage Tank	0.003	0.015	0.014	0.008	0.039

(Attractive Areas and Building Dimensions.)

Name of Safety Related Structure	Height[a] (meters)	Length (meters)	Width (meters)	Attractive Area (kilometers)
Auxiliary Building	32.31	58.52	34.75	0.0272
Reactor Building	79.25	42.67	42.67	0.1078
Electrical and Control Building	23.16	50.60	36.58	0.0167
Safeguards Building[b]	32.92	40.01	40.01	0.0258
Diesel Building	20.73	39.01	9.75	0.0098
Fuel Building	32.92	43.28	41.45	0.0266
Service Water Intake Structure	8.84	32.46	14.63	0.0031
Condensate Storage Tank	15.24	15.24	15.24	0.0050
Reactor Makeup Water Storage Tank	10.97	9.14	9.14	0.0024
Refueling Water Storage Tank	15.24	15.24	15.24	0.0050

a) Maximum heights of each building were generally used.

b) Due to the shape of this building, it was partitioned into two sections. The values for length and width are adjusted values.

TABLE 2.3-3
MEAN SEASONAL AND ANNUAL MIXING DEPTHS AND WIND SPEEDS AT TEXAS STATIONS NEAREST THE REGION (1960-1964)

	Midland		San Antonio	
	Mixing Depth (meters)	Wind Speed (meters/sec)	Mixing Depth (meters)	Wind Speed (meters/sec)
I. Morning				
Winter	290	5.7	459	5.8
Spring	429	7.5	748	6.5
Summer	606	7.2	915	5.7
Autumn	419	6.0	654	5.5
Annual	436	6.6	694	5.9
II. Afternoon				
Winter	1276	7.8	1112	6.8
Spring	2449	9.0	1552	7.2
Summer	2744	6.7	2119	6.0
Autumn	1887	6.7	1572	6.1
Annual	2089	7.5	1589	6.5

TABLE 2.3-15
VALUES OF MEAN, AVERAGE AND EXTREME DAILY MAXIMUM, AND AVERAGE AND EXTREME DAILY MINIMUM SURFACE TEMPERATURES (°F) AT FORT WORTH (1931 - 1960)

Month	Mean	Average Daily Maximum	Extreme Maximum[a]	Average Daily Minimum	Extreme Minimum[a]
January	46	56	88(1969)	35	4(1964)
February	49	60	87(1969)	39	12(1971)
March	56	67	91(1971)	44	19(1965)
April	65	76	95(1972)	54	30(1973)
May	73	83	96(1967)	63	42(1971)
June	82	92	105(1972)	71	51(1964)
July	85	96	105(1964)[b]	75	59(1972)[b]
August	85	96	108(1964)	75	56(1967)
September	78	89	102(1963)	68	46(1971)[b]
October	68	79	96(1963)	56	37(1966)[b]
November	55	66	88(1965)[b]	44	24(1970)
December	48	58	84(1966)	37	10(1963)
Annual	66	77	108(1964)	55	4(1964)

a) Period of record is July 1963 through 1973; year of occurrence given in parenthesis.

b) Record also occurred in earlier year(s).

a) LOCAL STANDARD TIME

TABLE 2.3-24
MEAN MONTHLY MIXING DEPTHS FORT WORTH[a] (May 1972-April 1976)

	Morning[b] (meters)	Afternoon[c] (meters)
January	409	771
February	449	1023
March	545	1057
April	547	1203
May	519	1323
June	619	1515
July	689	2120
August	662	2042
September	678	1451
October	481	1355
November	578	995
December	414	804

a) Based on surface observations at Fort Worth and upper air observations at Carswell AFB, Fort Worth from 5/72-10/73 and at Stephenville from 11/73-4/76.

b) Determined from intersection of 1200 GMT RAOB temperature profile and the potential temperature based on the surface RAOB pressure at 1200 GMT and the minimum surface temperature between 0200 and 0600 LST plus 5.0°C (P, C, and M cases excluded).

c) Determined as in b) except using surface temperature at 1500 LST.

4.	Receiver Accuracy	±0.04°F
5.	Current Driver Accuracy	±0.04°F
6.	Digital Recorder Accuracy	
	Input Resistor Accuracy	±0.05°F
	Input Accuracy	±0.05°F
7.	Square Root of the Sum of the Squared Tolerances	±0.071°F
8.	Analog Data Reduction Accuracy	±0.05°F
	System Accuracy[b]	
	Digital Recording	
	Square Root of the Sum of the Squared Tolerance of 1, 2, 3, 4, 5 and 6	±0.17°F

a) Measurement of delta temperature is made by comparing two identical sensors after having first calibrated out any difference between them at the reference temperature. The sensor error is then essentially the tracking error between the two sensors. This error includes accuracy and interchangeability and linearity. These errors plus those which are attributed to the signal conditioning electronics and recorders have been included in the analysis.

b) These values are well within the ±0.27°F criteria established by ANSI/ANS-2.5-1984, which is endorsed by Reg. Guide 1.23. Paperless digital recorder replaces previous analog recorders. Uncertainties calculated for paperless digital recorder do not exceed acceptance criteria requirements for digital channels. Calculations made for subsequent equipment upgrades computed uncertainties equal to or less than these uncertainties.

2.4 HYDROLOGIC ENGINEERING

2.4.1 HYDROLOGIC DESCRIPTION

2.4.1.1 Site and Facilities

The Comanche Peak Nuclear Power Plant (CPNPP) site is located approximately 65 miles southwest of the Dallas-Fort Worth, Texas, area, on a peninsula in Squaw Creek Reservoir (for a description of the Reservoir see Section 2.4.8.2). The Squaw Creek Reservoir (SCR) has a service spillway crest elevation of 775.0 feet. The calculated probable maximum flood level of Squaw Creek Reservoir is 789.7 feet. The station, which takes cooling water from one side of the peninsula and discharges to the other, has a site grade elevation of 810.0 feet.

The Safe Shutdown Impoundment (SSI) is formed by building a seismic Category I dam across an arm of the reservoir. The water level is maintained by an equalization channel between the SSI and SCR. Near the south end of the equalization channel, a non-intrusive, floating raft system has been added which bridges from the east bank to west bank of the channel. Details of the SSI Dam are presented in Section 2.5.6.

The Service Water Intake Structure is located on a bank of the SSI. The structure foundation is at elevation 749'0" with the top of slab at elevation 755'0". The operating deck of the structure is at elevation 796'0" with the pump discharge centerline at elevation 800'0". Access to the Service Water Intake Structure is provided by a personnel door and truck bay entrance at elevation 810'6".

The Containment Building is a completely closed, water-tight structure which cannot be affected by exterior flooding. Safety class equipment outside the Containment Building is located in the Safeguards, Fuel, Auxiliary, and Electrical and Control buildings. All exterior accesses to these buildings are above the 810 ft elevation with the exception of Turbine Building entrances to the Electrical and Control Building. This height is significantly above the maximum probable flood (see section 2.4.2). Protection against flooding of safety-related components and systems is discussed in Section 3.4.

A topographical map of the CPNPP site is shown in Figure 2.4-4, and changes made to the natural drainage features are indicated thereon.

The stability of the Squaw Creek Dam has been evaluated for construction and operating conditions, including conditions of maximum reservoir elevation and minimum tail water elevation, utilizing engineering properties of all embankment materials and all foundation materials, by normally recognized procedures such as that used by the Department of the Army, Corps of Engineers, as more fully described in Engineering Manual EM-1110-2-1902, “Stability of Earth and Rock-Fill Dams.” Squaw Creek Dam is not a seismic Category I structure.

Each building is equipped with a roof drainage system designed to effectively collect, pass and discharge the water volume resulting from a six-inch rainfall in one hour with a maximum intensity two inches in five minutes. The scuppers are in the parapet walls and the scupper invert elevation will not be more than three inches above the roof at the outside wall or not more than five inches above the low point of the roof. The roof drains and drain pipes are designed in accordance with “Roof Drain Design for Nuclear Project Safety Related Buildings” by Southern Services, Inc., dated December 8, 1972. The roofs of all nuclear-safety-related buildings are

designed to support an eight-inch maximum uniform depth of water in addition to the regular live loads considered (see Fig. 2.4-2 and 2.4-3). The parapet walls have relief openings to ensure that the eight-inch level will not be exceeded.

The onsite drainage system for the CPNPP site is a natural drainage system as outlined in Figure 2.4-4. As this figure shows, the safety-related buildings are located at a high point, with the surrounding grounds sloping towards the Squaw Creek Reservoir (SCR) to the north and the south including the Safe Shutdown Impoundment (SSI) to the south. The ground east and west of the buildings slopes towards the ditches as indicated on Figures 2.4-40 and 2.4-41. The onsite drainage system is further enhanced by the use of an underground storm drain system within the Protected Area/Vehicle Barrier System (PA/VBS) boundary which is supported by a series of catch basins, paved swales and rocked ditches. Surface runoff including that collected by the storm drain piping within the PA/VBS is discharged to the reservoirs on both sides of the peninsula either directly by a combination of open channel ditches and underground culverts or is collected at concrete designed Drainage Basins before being discharged to the applicable reservoirs via large underground pipe culvert systems. Although this level of detail is not shown on Figures 2.4-40 and 2.4-41, site plan drainage configuration changes and impact including that created by historical implementation and placement of new or modified design features, buildings, Security related features and other structures have been analyzed to address the adequacy of the onsite drainage system consistent with the design basis rainfall intensities and drainage requirements as described below. A possible clogging of any ditch or storm drain pipe within the PA/VBS boundary has been analyzed to not affect the system's water removal capacity.

In addition, the onsite drainage system is designed to remove the water resulting from a rainfall of six inches in one hour and 7.5 inches in two hours, in such a manner that the runoff is accomplished without ponds forming on the ground.

Further, the drainage system is designed to adequately drain a rainfall of 15 inches in one hour and 22 inches in two hours in such a way that there are no ponds which can back up into the structures and affect safety-related systems.

The design bases given above are consistent with the Probable Maximum Precipitation (PMP) as discussed in Section 2.4.3.1.

2.4.1.2 Hydrosphere

2.4.1.2.1 Regional Description

The Comanche Peak Nuclear Power Plant (CPNPP) site is located in the Squaw Creek catchment. Squaw Creek is a small tributary to the Paluxy River, which is a tributary to the Brazos River. The Brazos River and its tributaries constitute one of the principal river systems in the South-Central United States, extending from New Mexico, through Texas, to the Gulf of Mexico. The Texas portion of the Brazos River basin is illustrated in Figure 2.4-5.

The portion of the Brazos River catchment considered in this study is illustrated in Figure 2.4-6, a regional topographic map showing the site, existing and possible future reservoirs in the vicinity, and locations of the stream and rainfall gaging stations considered in this study. At gaging station 8-0910, east-southeast of the site, the Brazos River has a contributing catchment of 15,590 square miles [1].

For this study the most significant portion of the Brazos River catchment is that between Lakes Granbury and Whitney. In this reach, the Brazos River Channel is located in incised meanders formed by the river. These meanders may be the result of uplift of the area and/or sea level fluctuations after a mature meandering drainage pattern had been attained.

The meanders eroded through, and are flanked by, rock slopes confining the river within a relatively narrow channel. Immediately adjacent to the channel, within the meanders, is a narrow flood plain. Although accretion and erosion occur within the channel, as is typical of a meandering river, the well-defined meanders indicate that the channel location is closely confined. The geometry of the banks is governed closely by their location with respect to the meander pattern. The bank on the outside of a bend generally is steep, whereas the bank on the inside of the bend usually has a gentler slope.

2.4.1.2.2 Squaw Creek

Squaw Creek is a small, intermittent stream which drains parts of Hood and Somervell counties and empties into the Paluxy River, upstream of the confluence of the Brazos and Paluxy rivers. Squaw Creek frequently has no flow during dry periods. Squaw Creek Dam impounds SCR for CPNPP cooling water approximately 4.3 stream miles north of the creek's entrance into the Paluxy River. The principal features of the 64-square mile SCR catchment are illustrated in Figure 2.4-1. The Squaw Creek catchment is hydrologically similar to the Paluxy River basin.

The Squaw Creek watershed is underlain by sedimentary rocks of lower Cretaceous age (poorly cemented sandstone, limestone and shale) which dip gently to the east. The topography is influenced by the underlying geology, generally with steeper slopes in the limestone areas than in the shale and sandstone areas. Landforms are gently to steeply rolling. In the lower reaches of Squaw Creek, a small flood plain has developed.

Topographic maps prepared by the U.S. Geological Survey show a number of small man-made ponds in the catchment, some of which are in creek channels and others which are off-channel. The total volume of the on-channel and off-channel storage in these ponds has been estimated to be about 1150 acre-feet. There are three retaining ponds in the catchment for the purpose of mitigating oil spills. See FSAR Section 2.2.3.2.3. Other than these small ponds, there are no known control structures, weirs, or canals.

Tolar, with a 1970 population of 312 [2], is the only community in the catchment. The remainder of the catchment is largely ranchland with some cultivated areas.

2.4.1.2.3 Paluxy River

The Paluxy River basin is hydrologically similar to that of Squaw Creek and is used as a basis for developing hydrologic parameters for Squaw Creek and its subcatchments since Squaw Creek is ungaged. At gaging station 8-0915, near Glen Rose, the Paluxy River has a catchment of 410 square miles [1].

The Paluxy watershed also is underlain by sedimentary rocks of lower Cretaceous age (poorly cemented sandstone, limestone and shale) which dip gently to the east. The topography, governed somewhat by the geology, is generally stair-stepped in limestone areas and gently rolling in sandstone and shale areas.

There are no known control structures on the Paluxy River.

2.4.1.2.4 River Control Structures

The Brazos River is undergoing continuing development of reservoirs and control structures initiated for water supply, recreation and flow control. Table 2.4-1 lists important on-channel and off-channel reservoirs and dams upstream of Cox Bend. Cox Bend is shown on Figure 2.4-6. On-channel dams and reservoirs downstream of Cox Bend are identified on Table 2.4-2. Reservoir locations are represented on Figure 2.4-5.

Four potential future reservoirs are being considered on the Brazos between Possum Kingdom Reservoir and Lake Whitney [3]. These are described in Table 2.4-3 and their approximate locations are indicated in Figure 2.4-6.

2.4.1.2.5 Surface Water Users

No water rights have been issued on Squaw Creek, but two potential surface water users (irrigation) have filed claims to withdraw water. In due course, these claims will be evaluated by the Texas Water Rights Commission and either upheld or dismissed. The points of potential withdrawal are located within SCR limits, adjacent to the Hood-Somervell county line, and are listed in Table 2.4-4. No surface water users are known on the Paluxy River, downstream of the Squaw Creek confluence [4]. Cattle are watered from Squaw Creek and also probably from the Paluxy River.

There are numerous parties on the Brazos River downstream of the site vicinity who have applied for and/or received water allocations (hereafter called water users for non-irrigational and irrigational use). Non-irrigational users (municipal, industrial, mining and hydroelectric) are identified in Table 2.4-5 and on Figure 2.4-7.

Irrigational users are summarized by county in Table 2.4-6 and on Figure 2.4-7. The nearest irrigational water user below Squaw Creek Dam is approximately three stream miles downstream from the Paluxy and Brazos River confluence. The nearest extraction of water for public supply is at Waco, approximately 109 stream miles downstream of this confluence. There are no other known extractors of water for potable uses between Squaw Creek Dam and Waco.

2.4.1.2.6 Groundwater Environment

Most of the groundwater in the site region occurs in bedrock formations of very low permeability, although some does exist in shallow floodplain alluvium in stream valleys but is not withdrawn for use. The best producing formation is the Twin Mountains Formation which underlies the relatively impermeable Glen Rose Formation on which CPNPP and SCR are being constructed. Groundwater users near the site are described in Section 2.4.13.2 and presented in Tables 2.4-24 and 2.4-25.

2.4.2 FLOODS

2.4.2.1 Flood History

2.4.2.1.1 Brazos River

The maximum known flood on the Brazos River occurred in 1876 [1] well before flow monitoring began, and consequently, there is little quantitative data available on this flood. Flood records for the Brazos River at gaging station 8-0910, just upstream from the Paluxy River confluence, have been obtained since 1923 [1, 5, 6, 7]. Gage location is shown in Figure 2.4-6, and the annual maximum stage and discharge measurements for 1924 to 1975 are shown in Table 2.4-7. These records indicate that the highest water level recorded at gaging station 8-0910 was elevation 601.69 feet (May 27, 1957), corresponding to a discharge of 87,400 cubic feet per second (cfs).

For comparative purposes, Figure 2.4-8 shows the mean annual, the fifty-year, and the historical peak floods on the Brazos River. These correspond to flows of approximately 40,000 cfs, 110,000 cfs and 97,600 cfs, respectively, at gaging station 8-0910. The stage reached at station 8-0910 during the 97,600 cfs flood (May 18, 1935) was less than that of the 87,400 cfs flood due to backwater effects from the Paluxy River discharge.

The flood of record (elevation 601.69 feet) and the 1876 event are significantly lower than the CPNPP site grade (elevation 810 feet). Newly filled (1969) Lake Granbury and any subsequent flow-control facilities erected on the Brazos River watershed will further retard future flood levels.

2.4.2.1.2 Squaw Creek

There was no monitoring on the Squaw Creek watershed prior to 1966. A crest-stage partial-record station was installed in 1966 on Panter Branch, a tributary to Squaw Creek. Its location is shown in Figure 2.4-1, and the annual maximum stage and peak discharge measurements are presented in Table 2.4-8. In 1973, a continuous recording gage was installed on Squaw Creek at the State Highway 144 bridge, 2.1 miles upstream from the mouth of the creek. Annual peak discharges for the Squaw Creek gage during water years 1974 and 1975 are presented in Table 2.4-9.

2.4.2.1.3 Paluxy River

Periodic flow records were obtained in the 1920's and continuous monitoring began in 1947 at gaging station 8-0915 at Glen Rose [1, 5, 6, 7]. The gage location is shown on Figure 2.4-6, and the annual maximum stage and discharge measurements are provided in Table 2.4-10.

The maximum flood since 1876 is believed to have occurred on April 17, 1908. Information from a local resident has established the basis for an estimated stage at Elevation 637 feet at Glen Rose, corresponding to a discharge of 59,000 cfs for this event.

2.4.2.1.4 Flood Causes

All historical floods in the catchment area pertinent to the CPNPP site have been due to precipitation runoff into streams and rivers. The area is not subject to surges, tsunamis, or ice jams, and there have been no floods due to dam failure.

2.4.2.2 Flood Design Considerations

CPNPP safety-related facilities are designed to safely withstand all floods and flood waves which are remotely possible at the site. The crest of the service spillway, elevation 775 feet, has been utilized as the pre-flood condition. The planned design assures that the safety-related facilities of the CPNPP will not be adversely affected by this event. A summary of the consequences of flooding on all pertinent facilities is contained in Section 2.4.10. The PMF for Squaw Creek has been determined by imposing the 48-hour probable maximum precipitation (PMP) as obtained from Hydrometeorological Report No. 33 (HMR #33) [9] upon the catchment.

Studies show that the maximum sustained wind velocities in one general direction during major windstorms of record in most regions of the United States have averaged approximately 40 to 50 mph for a period of one hour [10]. In accordance with regional precedents set by the Corps of Engineers, wind tide and wave runup have been evaluated by procedures outlined in Engineering Technical Letter No. 1110-2-8 [10] using an overland wind velocity of 40-mph. Detailed analyses are described in Section 2.4.3.6.

Other events considered include the effect of domino-type failure of Morris Sheppard and DeCordova Bend Dams, and the effect of a 30-minute 80-mph wind coincident with the 10-year return period flood and with the maximum operating pool level. The domino-type failure is shown in Section 2.4.4.3 to have no effect on CPNPP or on Squaw Creek Dam. On SCR wave runup due to an 80-mph wind is shown in Section 2.4.3.6 to be less critical than for a 40-mph wind coincident with the PMF.

Events considered, but not applicable to CPNPP facilities include surge, tsunami, and ice flooding. Landsliding and/or reservoir slope failures are not an expected source of floodwaves. Natural slopes are 3:1 (Horizontal to Vertical), or flatter, except for occasional local portions of slope which are steeper (ranging to 2:1 or 1:1). Slope failures are improbable, but small localized sloughs conceivably might occur from erosion and/or weathering of the exposed edges of claystone seams from beneath overlying, more resistant rock zones. The small waves resulting from such failures will not adversely affect CPNPP facilities.

2.4.3 PROBABLE MAXIMUM FLOOD (PMF) ON STREAMS AND RIVERS

The PMF is defined by the Corps of Engineers as the “hypothetical flood characteristics that are considered to be most severe ‘reasonable possible’ at a particular location, based upon relative comprehensive hydrometeorological analyses of critical runoff producing precipitation and hydrologic factors favorable for maximum flood runoff.” The PMF for the SCR catchment has been derived synthetically, using procedures customarily applied by the U.S. Army Corps of Engineers. Results of the evaluations are summarized in Table 2.4-11 and Figure 2.4-9.

The flood routings for Squaw Creek Reservoir and Safe Shutdown Impoundment include allowance for rainfall on the surface of the reservoirs and the rainfall volumes are tabulated in Tables 2.4-11 and 2.4-15.

The nearby Brazos River has not been evaluated in detail for PMF because postulated upstream dam breaks are shown in Section 2.4.4 to be harmless to CPNPP facilities.

2.4.3.1 Probable Maximum Precipitation (PMP)

The PMP is the theoretically greatest precipitation over the applicable drainage area that would produce flood flows which have virtually no risk of being exceeded. From HMR No. 33 [9], it is found that the PMP is 25.5 inches in six hours on an area of 64 square miles in the CPNPP vicinity. Similarly, the PMP is 31.3 inches in 12 hours, 34.7 inches in 24 hours, and 39.1 inches in 48 hours. Table 2.4-11 lists the three hour rainfall increments, as divided for analyses.

For comparative purposes, a statistical method for estimating the largest rainfall likely to occur at a gaging station was applied to the nearby gaging stations shown on Figure 2.4-6. This procedure, developed by Hershfield [11], employs analyses of rainfall records to develop a statistical envelope defining the maximum precipitation occurrence. The method is applied to rainfall records from a single station, and a 24-hour estimate of maximum precipitation for that station is found. Results of analyses are compared to the 24-hour PMP and the maximum recorded rainfall in Table 2.4-12.

The amount of moisture present in the soil before the advent of the PMP, commonly referred to as the antecedent condition, is of importance in determining the amount of runoff produced by the PMP. The U.S. Bureau of Reclamation recommends “average” antecedent conditions [12]. Average conditions are defined as “the average of the conditions which have preceded the occurrence of the maximum annual flood on numerous watersheds.” The actual conditions assumed become relatively unimportant when considering 48-hour design storms because the initial 24-hour period of light rainfall saturates the ground prior to periods of intense rainfall.

The catchment area and site vicinity are gently to steeply rolling in character, with somewhat incised stream and river valleys. Relative relief is modest and does not require modification of the PMP value, or distribution, to account for orographic effects. Sub-basins within the SCR catchment are small; thus, catchment response to precipitation is relatively rapid. Therefore, postulation of storm centering is not of major importance, and the storm can be assumed to have uniform distribution and intensity over the entire catchment.

A comprehensive study of floods in Texas [5] indicates that snowmelt does not contribute significantly to river floods anywhere in the state. Similarly, no frozen-ground conditions are anticipated.

2.4.3.2 Precipitation Losses

Precipitation losses are estimated by evaluating the initial losses and the infiltration rates of the soils in a watershed. Evaluation of losses reveals that initial losses can be expected to be in the range of 0.5 inches with average antecedent conditions; and infiltration rates after presaturation will be in the range of 0.05 to 0.15 inches per hour. The PMF selected utilizes an initial loss of 0.5 inches and a conservative infiltration rate of 0.1 inch per hour as shown in Table 2.4-11.

These losses are based upon Corps of Engineers records for the Paluxy catchment shown below [13]:

			Losses (inches)			
Date of Flood	Rainfall (inches)	Duration (hours)	Initial (1st 3 hrs)	Balance	Total	Steady Loss (in/hr)
05/23/52	4.19	15	.85	2.24	3.09	.187
04/06/57	2.94	12	.47	1.36	1.83	.151

These values are indicative of the magnitude of precipitation losses expected on the SCR catchment due to its similarity to the Paluxy watershed in regard to general topography, geology, soil types and land usage. The values require evaluation, however, in light of some differences between the two watersheds, including: 1) the SCR catchment is generally not as steep as the Paluxy watershed; 2) the SCR watershed is much smaller; and 3) much of the relatively level, low-lying portion of the SCR catchment will be inundated by the reservoir.

Although the first difference described above tends to increase the precipitation losses on the SCR catchment in relation to that of the Paluxy River, the other two differences indicate a decrease in losses. Smaller drainage areas, such as the SCR catchment, generally have lower losses than larger areas, and submergence of much of the creek alluvium removes a section of the catchment which should have the most infiltration capacity. Thus, it is prudent to adopt lower estimates of losses on the SCR catchment. This conclusion is further supported by the relatively short duration of the available historical storms studied, in comparison to the 48-hour storm used in computing the PMF. In view of these factors, an initial loss estimate of 0.5 inches and an infiltration rate of about 0.1 inch per hour is considered appropriate for the catchment.

2.4.3.3 Runoff Model

2.4.3.3.1 Description of Squaw Creek Reservoir Catchment

Figure 2.4-1 illustrates the 64-square mile SCR catchment and the reservoir limits corresponding to a selected flood-stage at Elevation 780 feet.

The pre-flood condition reservoir level is assumed to be Elevation 775 feet.

During the PMF, pool level will rise from Elevation 775 feet (area 3,272 acres) to Elevation 789.7 feet (area 3,863 acres).

2.4.3.3.2 Synthetic Hydrographs

Synthetic methods for developing a runoff model have been undertaken. Three methods of synthetic hydrograph development were considered:

1. Use of Snyder's Unit hydrograph relations presented by the U.S. Army Corps of Engineers (USACE) [14].

2. Use of dimensionless hydrographs presented by the Soil Conservation Service (SCS) [14].

3. Use of triangular hydrograph techniques presented by the U.S. Bureau of Reclamation [12].

The empirical relations developed by Snyder have also been shown to be reliable through widespread usage. To employ this method, two coefficients which depend upon drainage basin characteristics are computed from hydrologic records for a representative portion of the drainage area under study, or for nearby catchment of similar characteristics [15]. Snyder's method was adopted for development of a runoff model for Squaw Creek.

2.4.3.3.3 Hydrograph Development

For purposes of analyses, the SCR catchment has been divided into three areas, as shown on Figure 2.4-1 and described below:

1. The Upper Squaw Creek catchment, which consists of about 38 square miles of land located above the reservoir area.

2. The Lower Squaw Creek catchment which consists of about 20.3 square miles of land located around the fringes of the reservoir. This area is actually comprised of a number of very small catchments, which are considered together for reasons of clarity and convenience.

3. The Squaw Creek Reservoir Area

The Corps of Engineers has developed unit hydrographs from gaging station records for two nearby watersheds, the Paluxy River and the Clear Fork of the Trinity River. The pertinent data from these studies [13] is summarized below:

	Drainage Area (Sq. Mi.)		
Paluxy River	361	.60	420
Clear Fork (upper portion)	210	1.50	480

The lower portion of the SCR catchment (see Figure 2.4-1) is generally similar to the Paluxy River watershed. The upper portion is considered to have characteristics falling between those of the Paluxy River and Clear Fork. These considerations lead to the adaptation of the following coefficients for the SCR catchment:

			Basis
Upper 38.0 Sq. Mi.	1.1	440	Combination of Paluxy & Clear Fork
Lower 20.3 Sq. Mi.	.3	420	Paluxy

All other information needed to apply Snyder's relationships (such as area, length, and center of gravity of the catchments) has been derived from U.S.G.S. quadrangle maps. These data are summarized in Table 2.4-13.

The unit hydrographs are shown in Figure 2.4-10.

2.4.3.3.4 Non-Linearity

High rainfall rates associated with intense storms may result in above normal concentrations of runoff (non-linearity) because of a more severe rainfall distribution and increased hydraulic efficiencies.

The USACE recommends increasing hydrograph ordinates by 25 to 50 percent during the period of most intense rainfall [14]. In view of this, the hydrograph for the upper SCR catchment was increased by 30 percent during the most intense period of rainfall (See Table 2.4-13). This magnitude of increase is considered applicable for a drainage basin of 38 square miles.

2.4.3.3.5 Translation of Inflows

The size and shape of the reservoir in relation to the catchment area suggest that there will be no significant translation time from inflow points to the dam and CPNPP site locations; accordingly, no delay is introduced into the computations.

2.4.3.4 Probable Maximum Flood Flow

The PMF inflow and outflow hydrographs to SCR resulting from the PMP are presented in Figure 2.4-9. As explained in Section 2.4.3.1, snowmelt was not considered in establishing the PMP.

Except for a few existing small farm ponds, there are no present or planned structures upstream of SCR; therefore, the effect of such structures was not considered in developing the PMF hydrograph.

The PMF was routed through the SCR assuming the reservoir level at the beginning of the PMF was at elevation 775, the service spillway crest elevation. All discharge was assumed to occur over the uncontrolled spillways of Squaw Creek Dam.

The current SCR operating practice (see Section 2.4.8.2.1) of pumping makeup water to cause a small flow over the service spillway may routinely raise the SCR level. This small SCR level increase and the resulting small flow over the service spillway is negligible when combined with the maximum postulated precipitation and flooding analysis results and has insignificant impact on the PMF peak reservoir level.

All streams in the SCR basin empty directly into SCR; therefore no channel routing coefficients were required. The applicability of the stream course response model to handle the PMF is discussed in Section 2.4.3.3.4. The ability of the SCR dam to withstand the PMF and coincident wave action is discussed in Section 2.4.3.6.

2.4.3.5 Water Level Determinations

The mass curve, the capacity-area-depth curves, and the spillway rating curves (Figure 2.4-9) are used in routing the PMF through the reservoir to evaluate water level. The resulting peak reservoir level is Elevation 789.7.

In routing, the reservoir water surface has been assumed to be nearly horizontal, and the volume of water in the reservoir has been assumed to be directly related to the reservoir elevation. These are reasonable assumptions in view of the shape and depth of the SCR. These assumptions allow the principle of continuity expressed as a storage equation $(\hat{I}\Delta t - \Delta s = \bar{\theta}\Delta t$, where $\hat{I}$ and $\bar{\theta}$ are the average rates of inflow and outflow for the time Δt, and Δs is the change in water volume during time Δt) to be applied directly to the routing problem [16].

2.4.3.6 Coincident Wind Wave Activity

The magnitude of the wind tide and wave runup are dependent upon the wind velocity, fetch and reservoir depth. The wind direction must coincide with the fetch direction. An overland wind velocity of 40 miles per hour has been approved by the USACE for use in determining freeboard requirements in the Fort Worth District. This 40 mph wind velocity is the highest that may reasonably be assumed to occur coincidentally with the probable maximum flood [17].

The effective fetch length for wave generation was determined for the center of Squaw Creek Dam (fetch of 1.28 miles) and for the exposed side of the CPNPP plant location (fetch of 1.25 miles). It was also determined for the Safe Shutdown Impoundment Dam and the protected side of the CPNPP plant location, but freeboard requirements were found to be less than two feet for these locations, so discussion is not included here. Computation of effective fetch considered radial lines at angles up to 42 degrees from the central or primary fetch line, as recommended by the USACE [10].

The average depth of the reservoir at PMF, Elevation 789.7 feet, is approximately 55 feet, and the longest theoretical deep-water wave length (for waves reaching the center of Squaw Creek Dam) is 46 feet, so the ratio of water depth to wave length is well over one-half, and the reservoir can be considered to have “deep water” [10].

Computation [10] utilizing data for wind velocity, fetch length, and reservoir depth yield the results shown in Table 2.4-14. The Table illustrates the maximum runup and setup of smooth and riprapped banks on the Squaw Creek Dam and at the exposed side of the CPNPP plant area. As

can be seen from the Table, wave runup and wind tide at the dam and plant are about 4 and 5.0 feet and elevations reached are 793.7 feet and 794.7 feet, respectively. Due to the much shorter fetch available around the area, water level elevation reached at the SSI is about 791.3 feet. All plant facilities are above the maximum wave runup and setup elevation of 794.7 feet. The Service Water Intake Structure is the only safety-related structure subject to wave action. The elevation at the operating deck is approximately 796, above the maximum expected wave runup. Section 2.4.10 discusses the effect of wave runup and wind tide on all pertinent safety-related facilities.

2.4.3.7 Flood Evaluations for Safe Shutdown Impoundment

[redacted] Water can pass freely between the SSI and SCR, and the water surface in both water bodies normally will be at the same elevation. Figure 2.4-11 is a graph of the discharge characteristics of the SSI spillway. Table 2.4-15 outlines predicted performance of the SSI during occurrence of simultaneous Probable Maximum Floods on the overall SCR watershed and the SSI watershed. The maximum level reached in the SSI during the PMF is computed to be 790.5 feet, leaving a freeboard in the SSI of 5.5 feet. Further details on the Safe Shutdown Impoundment Dam are given in Section 2.4.8.2.2. Table 2.4-16 gives the unit hydrograph parameters for the SSI watershed, and Figure 2.4-12 shows the unit hydrograph for the SSI watershed. A non-intrusive, floating raft system has been located near the south end of the equalization channel. This floating raft system bridges from the east bank to west bank of the channel. The raft system is retained at its designated position through the use of bollards on the banks of the channel. These bollards function as bumpers for the raft system. Should the equalization channel experience flooding conditions, the floating raft system is designed to freely float on the water surface, even if the floats are punctured. If the water level exceeds an elevation above approximately elevation 781 feet, the raft system will float over the bollards and, due to the direction of flow through the channel, the raft system will be pushed away from the SSI and into the SCR. As a result, this floating raft system will not affect the design function of the equalization channel to freely pass water to the SCR under flooding conditions up to a PMF.

2.4.4 POTENTIAL DAM FAILURES (SEISMICALLY INDUCED)

There are no impoundments other than small farm ponds on the SCR catchment; therefore, a postulated dam failure upstream on Squaw Creek is not appropriate for the CPNPP facilities. The farm ponds on the catchment have a combined volume which is less than one percent of the reservoir volume and are insignificant.

Failure of Squaw Creek Dam itself presents no danger of flooding the CPNPP, as the Station is above the PMF water level. The possibility of damage to Squaw Creek Dam by backwater due to flooding on the Brazos River in the event of a postulated domino-type failure of Morris Sheppard Dam and DeCordova Bend Dam is ruled out in Section 2.4.4.3.

2.4.4.1 Reservoir Description

Present and possible future reservoirs which might be considered to have an influence on the site from a safety or water-supply standpoint are described in Tables 2.4-1 through 2.4-3, and their locations are shown in Figures 2.4-5 and 2.4-6.

2.4.4.2 Dam Failure Permutations

Considering CPNPP safety, the most severe dam failure permutation conceivable is the failure of Morris Sheppard Dam and the subsequent domino-type failure of DeCordova Bend Dam. The 25-year floods of both the Brazos and Paluxy rivers can be added into the effects of the combined dam breaks without significantly intensifying the results. Failure of the Lake Whitney Dam, downstream, would not have an adverse effect on CPNPP.

The detailed analysis of the most severe dam failure permutation is presented in Section 2.4.4.3 and the effect of landslides into the reservoir is discussed in Section 2.4.2.2.

There will be no commercial water traffic on SCR, and no possible blockage of any water course in the site region could affect the plant.

2.4.4.3 Unsteady Flow Analysis of Potential Dam Failures

The possibility of damage to Squaw Creek Dam due to failure of Morris Sheppard Dam and DeCordova Bend Dam was examined by initiating a number of highly conservative simplified evaluations which would establish conservative water levels. The results of these studies clearly indicate that there is no possibility of flood damage to the CPNPP site and Squaw Creek Dam. The toe of Squaw Creek is above Elevation 640 feet, approximately 60 to 90 feet higher than the bankfull elevation of the Brazos River at the Brazos River - Paluxy River confluence (Elevation 560 feet). The maximum wave height that could be generated by complete and instantaneous removal of DeCordova Bend Dam is about 37 feet, according to dam break calculations described in Section 2.4.4.3.3.

Prior failure of Morris Sheppard Dam is not expected to increase this wave height significantly due to the modifying effects of 145 miles of river channel between Morris Sheppard and DeCordova Bend Dams. Although calculations (Sections 2.4.4.3.1) show that a wall of water over 60 feet high would be initiated by the complete and instantaneous removal of Morris Sheppard Dam, routing by the method of coefficients (Section 2.4.4.3.2) shows that the wall would have decayed during translation to DeCordova Bend Dam. Rather, there would be a flood, the peak of which would arrive some five hours after initial inflow to Lake Granbury reservoir had begun. The break in the DeCordova Bend Dam is postulated to occur when the reservoir level becomes full. Therefore, the reservoir inflow from an upstream dam break would serve to sustain the high rate of outflow through the break in DeCordova Bend Dam rather than to increase the initial outflow (height of water wall) significantly.

Even with the ultra-conservative assumption that the combined wave created by the dam breaks remained undiminished in traveling below DeCordova Bend to the Paluxy River - Brazos River confluence, the flood wave would fall more than 40 feet (elevation) short of reaching the toe of Squaw Creek Dam.

In view of the highly conservative assumptions made in the following flood analyses, the results are regarded as a very conservative upper limit on the river level in the event of the domino-type failure, rather than a refined estimate of the flood to be expected.

2.4.4.3.1 Morris Sheppard Dam Break

[redacted]

Evaluation assumptions:

1. Complete and instantaneous removal of dam.
2. [redacted]
3. Channel is frictionless, rectangular and horizontal.
4. No water downstream of dam.
5. Vertical accelerations are negligible

These highly conservative assumptions allow the following analysis to be made, using the method shown by Henderson [19] and Chow [20].

Crest Velocity

= $(gy)^{1/2}$ *

= $((32.2 \text{ ft/sec}^2) \times (145 \text{ ft}))^{1/2}$

= 46.5 mph

Trough Velocity (velocity of wave downstream)

= $2\ (gy)^{1/2}$

= 2 x (46.5 mph)

= 93 mph

Velocity of water through dam site

= $2/3\ (gy)^{1/2}$

= 2/3 (46.5 mph)

= 31 mph

Discharge

= $8/27\ (g)^{1/2}y^{3/2}W$

= $8/27\ (32.2\ ft/sec^2)^{1/2}\ (145\ ft)^{3/2}(1600)$

= 4,700,000 cfs

Time of constant discharge (assuming discharge will remain until lake is empty)

= 600,000 ac-ft/(.0826 ac-ft/cfs-hr) (4,700,000 cfs)

= 1.5 hours

where

t = length of time interval, in this case one hour.

X = a constant dependent upon channel characteristics.

g = acceleration of gravity

y = height of water surface exposed upon dam removal

2.4.4.3.2 Routing From Morris Sheppard Dam to DeCordova Bend Dam

Travel times for floods between Morris Sheppard Dam and DeCordova Bend Dam cannot be determined with accuracy because of such factors as incidence of rain and runoff accumulation within the reach. However, there are some data regarding water movement on the river. It has been found that it takes about two days for normal turbine releases from Morris Sheppard Dam to reach DeCordova Bend Dam [3]. This is equivalent to a velocity of under three mph. Flow travel time studies on the Brazos River between Lake Whitney and Richmond show that velocities vary between 1.6 mph and 3.8 mph. Travel time is greatest for low flows and least for small floods, and then increases again as flows become very large [21]. These data are inconclusive but they seem to indicate that the average velocity of flow from a dam break would be in the order of three or four mph.

The length of river channel required to reach a terminal velocity is not known; therefore, in the evaluations the flow from the Morris Sheppard Dam Break has been conservatively assumed to continue unbated at 31 mph, the theoretical velocity of flow through the dam section.

The distance traveled to Lake Granbury is 144.5 miles, and the lake is 33.5 miles long; therefore, travel time is indicated to be on the order of five hours, with one hour of this being flow along the reaches of Lake Granbury.

Routing was by the method of coefficients (Muskingum) [22] through a reach using total flood-wave travel equal to 4xt* and an X* of 0.3 (deemed appropriate for a wide rectangular channel where changes in discharges are small) and through a reach using total flood-wave travel equal to t and an X of zero (for reservoir-type storage routing). This evaluation yields an outflow hydrograph having a base time of over 12 hours and a peak flow of about 1,900,000 cfs, well under half of the theoretical initial discharge of 4,700,000 cfs.

2.4.4.3.3 DeCordova Bend Dam Break

[redacted]

Assumptions made:

1. DeCordova Bend Dam holds until lake level reaches top of dam.
2. Complete and instantaneous removal of dam.
3. [redacted]
4. Channel is frictionless, rectangular and horizontal.
5. No water downstream of dam.
6. Vertical accelerations are negligible.

These highly conservative assumptions allow the following analysis to be made:

Crest Velocity

$= (gy)^{1/2}$

$= (32.2 \text{ ft/sec}^2 (84 \text{ ft}))^{1/2}$

$= 52 \text{ ft/sec}$

$= 35 \text{ mph}$

Trough Velocity

$= 2 (gy)^{1/2}$

$= 2 (35 \text{ mph})$

$= 70 \text{ mph}$

Velocity of water through dam site

$= 2/3 (gy)^{1/2}$

$= 2/3\ 35$

$= 23 \text{ mph}$

Discharge

$= 8/27\ (g)^{1/2} y^{3/2} w$

$= 8/27\ (32.2\ ft/sec^2)^{1/2} (84\ ft)^{3/2} (2200\ ft)$

$= 2{,}800{,}000\ cfs$

Depth of water at dam site

$= 4/9\ Y$

$= 4/9\ (84\ ft)$

$= 37\ ft$

Theoretical time of discharge

$$= \frac{(2)(\text{length of lake})}{(\text{velocity of wave})}$$

$$= \frac{(2)(33.5\ mi)}{35\ mph}$$

$= 2\ hours$

Assuming no inflow, the 2,800,000 cfs discharge would empty Lake Granbury in less than a half hour. But the inflow from Possum Kingdom Reservoir would provide additional water to maintain the 2,800,000 cfs flow for two hours. After the two hour period, flow would diminish until the remaining 65,000 acre feet are discharged.

2.4.4.3.4 Routing from Decordova Bend

[redacted] Thus, there is no possibility of dam breaks on the Brazos River affecting the safety of the CPNPP.

In the event that other dams are constructed between Morris Sheppard Dam and DeCordova Bend Dam, their presence should in no way endanger the safety of the CPNPP, even in the case of a domino-type failure.

[redacted]

2.4.4.3.5 Consideration of Antecedent Flow

In the preceding description of analyses, river channels have been assumed to be dry. Inclusion of water in the river (antecedent flow) would not have a significant effect on the results of the dam break analyses. For example, the 25-year flood on the Brazos River would contribute only about 90,000 cfs (refer to Figure 2.4-13), which is only 3.2 percent of the theoretical flow from the dam breaks.

2.4.4.4 Water Level at CPNPP

The Station site can in no way be endangered by any dam breaks or series of dam breaks, as it is over 110 feet above postulated maximum water levels.

2.4.5 PROBABLE MAXIMUM SURGE AND SEICHE FLOODING

2.4.5.1 Probable Maximum Winds and Associated Meteorological Parameters

The probable maximum sustained over-land wind selected for evaluation of wave action of the maximum operated reservoir elevation is 81 mph. The wind has an estimated return period of 200 years [23].

2.4.5.2 Surge and Seiche History

There are no existing large bodies of water near the site that would allow development of either surge or seiche; therefore, there is no history of surge and seiches in the site vicinity.

2.4.5.3 Surge and Seiche

The small size, relatively shallow depth and irregular shape of Squaw Creek Reservoir indicates that there is a minimum probability of either surges or seiches occurring in the reservoir. Therefore, surge and seiche should not be considered significant at this site.

2.4.5.4 Wave Action

The effect of the maximum sustained wind on the reservoir surface has been evaluated in Section 2.4.5.1. This wind is considered coincident with a 10 year return period flood elevation in Squaw Creek (778.1 feet). Results of the wind wave activity calculation are presented in Table 2.4-14. With an effective fetch of 1.28 miles, computations indicate that the significant wave height will be approximately five feet with a period of 3.9 seconds. The maximum wave height will be about eight feet with a setup of 0.2 feet and runup of 6.8 feet [10].

This will occur at Squaw Creek dam as illustrated in Table 2.4-14.

The wind penetrated waves on the SSI are less than those on SCR due to the much shorter fetch available around the SSI area (see Figure 2.4-14, Figure 2.4-15 and Table 2.4-14).

2.4.5.5 Resonance

Due to the irregular shape and sloping sides of SCR and SSI, wave resonance will not have any significant effect on the maximum water elevation.

2.4.5.6 Runup

The maximum water elevation reached due to wave runup and setup at the plant site, Squaw Creek dam and SSI dam are 794.7 feet, 793.7 and 791.3 feet, respectively. All plant facilities will be above the maximum wave runup elevation of 794.7 feet.

The Service Water Intake Structure will be the only safety-related structure subject to wave action or wave runup. The operating deck will be approximately elevation 796', well above the maximum expected wave runup.

2.4.6 PROBABLE MAXIMUM TSUNAMI FLOODING

This site is nearly 300 miles from the Gulf of Mexico and the plant will be over 800 feet above sea level. Therefore, tsunami flooding will not occur.

2.4.7 ICE FLOODING

The Texas climate is too warm to allow the development of significant ice on any lake. Certainly there are no records of any major river in Texas freezing over at any time, so the possibility of ice flooding can be discounted.

2.4.8 COOLING WATER CANALS AND RESERVOIRS

2.4.8.1 Canals

No canals are involved.

2.4.8.2 Reservoirs

2.4.8.2.1 Squaw Creek Reservoir (SCR)

SCR is a cooling lake for CPNPP. The location and configuration of the reservoir are shown in Figures 2.4-5 and 2.4-6. Table 2.4-17 gives the area and capacity characteristics of the SCR site, based on planimeter measurements from U.S. Geological Survey quadrangle maps entitled Hill City, Texas, and Nemo, Texas, scale 1:24,000. The volumes and areas indicated are those of the entire reservoir, including the reserve storage within the Safe Shutdown Impoundment (SSI) described in Section 2.4.8.2.2 below. The performance capability of SCR as operational cooling pond was evaluated through mathematical modeling as documented in Reference [40].

During some periods and especially in summer months, the pumping of makeup water may be utilized to raise the level of SCR above the crest of the service spillway to keep a small flow of SCR water going over the crest of the service spillway even in the absence of rain. This practice enhances the cooling capacity of the reservoir.

1. Squaw Creek Dam

[redacted]

2. Spillways

[redacted]

Design bases for the service spillway at Squaw Creek Dam are as follows:

a. Spillway width: [redacted]

b. Design Head: [redacted]

c. Crest elevation: [redacted]

d. Depth of approach channel below crest: [redacted]

e. Slope of upstream face of weir: [redacted]

f. Type of spillway crest: [redacted]

g. Manning's "n" of approach channel: [redacted]
(Ref: EM 1110-2-1603)

h. End contraction effects from Engineering Manual Part CXVI

i. Entrance loss assumed to be 0.1 V**2/2g for approach channel

j. Coefficients of Discharge from Figure 251, Design of Small Dams, 1973 Edition

Design for rip-rap lining on the sides of the discharge channel of the service spillway was determined using U.S. Army Corps of Engineers EM 1110-2-1601 (1 July 1970) and

supplemental ETL 1110-2-120 (14 May 1971) along with U.S.A.E.W.E.S. Hydraulic Design Chart 712-1 (Revised September 1970). Unit weight used for rip-rap stone was 145 pcf. Average velocities of water flow were determined from backwater analyses starting at the confluence of the discharge channel with Squaw Creek and progressing through the channel to the stilling basin.

Velocities ranged from 16.2 fps in the lower reach of the channel to five fps just below the stilling basin. The termination of the rip-rap at the end of the discharge channel was designed based on the possibility that future stream bed degradation in Squaw Creek could cause critical depth of flow at the end of the rip-rap lining with a corresponding local flow velocity of 18.5 fps. Rip-rap bedding beneath the stone layer was designed as a filter to prevent migration of soil or bedding material through the slope protection layer. The bottom of the channel is sound limestone and did not require rip-rap protection.

The emergency spillway discharges into a tributary of Squaw Creek whose confluence with Squaw Creek is 7,000 feet downstream of the dam. A water surface profile in Squaw Creek showed that the water level at the toe of the dam will reach Elevation 656.0 during a Probable Maximum Flood. The tributary, through which the emergency spillway discharge will flow, is separated from the dam by a large hill composed of a thin overburden overlying limestone. The Squaw Creek Dam embankment will not be endangered by flows through the emergency spillway.

Design bases for the emergency spillway at Squaw Creek Dam are as follows:

a. Spillway width: [redacted]

b. Crest elevation [redacted]

c. Length of level section at elevation 783.0: [redacted]

d. Slope of spillway downstream from level section: [redacted]

e. Manning's "n" of spillway channel: [redacted]
(Ref: Chow: Open-Channel Hydraulics)

f. Side slopes: 1 vertical on 3 horizontal

g. Entrance loss assumed to be 0.1 V**2/2g.

The emergency spillway at Squaw Creek Dam is not lined. A concrete wall at Elevation 783.0 on the emergency spillway crest serves as the spillway's erosion control structure. Its purpose is to maintain a uniform elevation for the entire length of the crest. The wall is anchored in limestone. The maximum velocity along the emergency spillway during a Probable Maximum Flood is 10 fps. Velocities at the downstream edge of the spillway will be higher. These velocities will cause some erosion damage. The erosion will not be severe since the emergency spillway cut is into limestone. In places, surface materials (up to 2 feet thick) overlying the limestone consist of softer materials, graded for drainage. The frequency of operation of the emergency spillway is in excess of 100 years. The erosion damage will not endanger the dam or reduce its storage capacity.

Location of the spillways are indicated on Figure 2.1-2.

3. Flood Levels

Routing of the PMF through the reservoir has been discussed in detail under Section 2.4.3. The maximum high water level during the PMF would be Elevation 789.7, leaving a freeboard allowance of 6.3 feet, which is more than adequate to accommodate wave runup and wind tide on rip-rapped slopes as shown in Section 2.4.3.6.

In order to evaluate the probable frequency of flows through the emergency spillway cut, inflow hydrographs were also computed for floods having 50-year and 100-year probable recurrence intervals, using rainfall data developed for those frequencies by the U.S. Weather Bureau [24]. It was found that the 100-year flood would involve less total runoff than the volume of surcharge storage available between the crest of the service spillway and the crest of the emergency spillway, and that the 100-year storm would, therefore, not cause flow through the emergency spillway.

4. Brazos River Diversion System

Supplemental water from Lake Granbury on the Brazos River will be conveyed by pipeline to SCR when required. The pipeline is 48 inches in diameter, with a design delivery capability of 65.1 million gallons per day (MGD). To allow for one pumping unit being temporarily out of service, the station includes four pumps with 21.7 MGD of rated capacity each, for a total installed name-plate capacity of 86.8 MGD.

5. Service Outlet

Service outlet facilities are located at the right (south) abutment of the dam and consist of an intake tower and outlet conduit. The tower has ports at various levels in the reservoir to allow selective taking of water. Backup closure facilities are provided to protect against loss of storage due to inability to close a valve or a gate.

2.4.8.2.2 Safe Shutdown Impoundment (SSI)

A portion of the arm of the reservoir that is formed by the channel of Panther Branch is utilized as a Safe Shutdown Impoundment, holding water for normal and emergency cooling use. The area and capacity characteristics of this cooling water pond are given in Tables 2.4-18 and 2.4.19. The secondary reservoir is separated from the main body of the reservoir by a rock-fill dam. An open channel was excavated through the narrow ridge to the southwest of the SSI Dam to connect the SSI with the main body of the reservoir. The floor of the channel is at elevation 769.5, six inches below the normal minimum operating level, and under normal operating conditions water will pass back and forth to keep the large and small reservoir surfaces at the same elevation. If the level in the main reservoir should drop due to some emergency, the SSI Dam will hold back between 284 acre-feet and 367 acre-feet of reserve water to allow continued cooling and safe shutdown of the plant.

Details of the SSI Dam embankment are shown in Figure 2.4-21. The middle zone is of select, impervious material, wetted and rolled and carried down to impervious foundation material for effective cut-off.

[redacted]

Design bases for the spillway at the Safe Shutdown Impoundment are as follows:

a. Spillway width: [redacted]

b. Side Slopes [redacted]

c. Slope of Spillway channel: [redacted]

d. Manning's "n" of spillway channel: (Ref: Chow: Open-Channel Hydraulics) [redacted]

e. Entrance loss assumed to be 0.1 V**2/2g

f. Exit loss assumed to be V**2/2g

The spillway channel is in limestone and is unlined. The velocity through the spillway will reach 10.3 fps. A concrete erosion slab was constructed in the channel to maintain the control level at elevation 769.5.

The rock used to construct the outer zones of the SSI dam was selectively quarried and processed from planned plant site excavations to produce a reasonably well graded product conforming to the limits shown on Figure 2.5.6-12. Basic consideration in selecting the rock gradation were seismic performance and protection of the interior filters. Normal construction techniques for the rock fill resulted in larger rock sizes accumulating on the outer edges of the slopes. Analysis of wave protection requirements was based on an average over-water wind of 81 mph (probable maximum wind - 200 year frequency) over the effective fetch distance. The method of computing the effective fetch distance set forth in Department of Army, Office of the Chief of Engineers ETL 1110-2-221, 29 November 1976, was adopted. Comparison of the as constructed conditions with conventional rip rap protection requirements as set forth in EM-1110-2-2300 (1 MARCH 1971) indicates adequate protection. To assure continued performance of the SSI, the planned annual inspection (see Section 2.5.6.8.1) of the dam will specifically include observations of slope protection.

Estimated sediment production from the Panther Branch watershed above the SSI during the 40-yr projected service life of CPNPP was derived based on analytical procedures for small watersheds as described in Reference [38]. The anticipated reduction in storage capacity of the SSI during that period due to accumulation of sediment was found to be 91 ac-ft, of which 85 ac-ft would be below elevation 770.0 and the remaining 6 ac-ft between elevations 770.0 and 775.0. Comparative plots of area and capacity characteristics before and after sedimentation are shown in Figure 2.4-22. Table 2.4-19 outlines the predicted area and capacity values at the end of the 40-year period.

Inspections of the service water intake channel for sedimentation buildup will be performed at the frequencies stated in Regulatory Guide 1.127. This inspection will consist of a direct measurement of sediment depth at the bottom of the intake channel at a minimum of five

locations along its length. Measurements will be taken at approximately the same location each time the inspection is performed.

If it is determined that, as a result of these inspections, the sediment has accumulated enough to increase the bottom elevation one and one-half (1.5) feet over the entire length of the inspection area, then measures will be employed to remove the sediment from the intake channel. At that time, procedures will be developed and approved to accomplish this task.

A detailed layout of the SSI design features is given in Figure 2.4-23.

Seismic Design Criteria for the SSI are discussed in Section 3.7.

The ability of the SSI to meet criteria of Regulatory Guide 1.27 is discussed in Section 9.2.5.

2.4.9 CHANNEL DIVERSIONS

The SCR catchment has developed streams with distinct valleys and has sustained numerous farm ponds. Therefore, diversion of water from the catchment appears impossible. The reservoir is formed in the Glen Rose formation, a predominately limestone sequence. Information developed regarding this formation indicated it is relatively impermeable and free of sinkholes and solutioning. Thus, significant loss of water is improbable.

Lake Granbury, which is on the Brazos River, will be a major source of makeup cooling water. The loss of Lake Granbury makeup water due to the diversion of the Brazos River is highly improbable. Above Lake Granbury, the Brazos River channel is cut into bedrock which precludes any reasonable possibility of the river changing its channel significantly within the life of the CPNPP and thus affecting the supply of water.

Extraction of groundwater, oil, and gas from the region is relatively nominal. It is concluded that subsidence sometimes associated with these extractions will not occur in the vicinity of the CPNPP. The potential of subsidence at the site is discussed in detail in Section 2.5.1.2.6.

2.4.10 FLOODING PROTECTION REQUIREMENTS

Safety-related structures, except the Service Water Intake Structure and the Electrical and Control Building, are not subject to flooding, wave action, or wave runup and do not require flood or wave protection. The plant grade is at elevation 810 ft, and the peak SCR level is at elevation 789.7 ft for the probable maximum flood (PMF). (See Section 2.4.3.3.1)

The Service Water Intake Structure is protected from the effects of wind wave activity on the Squaw Creek Reservoir by the Safe Shutdown Impoundment (SSI) Dam. An overland 40-mph wind is assumed to occur coincidentally with the SSI PMF level of 790.5 ft. Since the wind wave activity at the Service Water Intake Structure is negligible, there are no significant dynamic forces to be considered. (See Section 2.4.5.) The design hydrostatic load includes the maximum runup elevation (see Section 2.4.3.6) caused by the 40-mph wind coincident with the PMF.

Design criteria for the Service Water Intake Structure are discussed in Section 3.8.4.1.4. The Electrical and Control Building would be subject to flooding if flood protection measures were not taken. These measures are described in Sections 3.4 and 13.5. It is not necessary to implement any other flood protection measures or emergency procedures.

2.4.11 LOW WATER CONSIDERATIONS

The SCR provides the cooling water for plant operation. In general, the combined amounts of natural and induced evaporation, plus releases for control of chemical quality, are more than the available runoff from Squaw Creek. Supplemental water will be brought from Lake Granbury on the Brazos River, in accordance with an agreement by and between Brazos River Authority and TP&L, TESCO, and DP&L, to hold the reservoir at the required operating elevation [39]. This agreement has no limitations which could be placed on the water that would have an adverse effect on safety-related makeup.

2.4.11.1 Low Flow In Rivers And Streams

Low flow in Squaw Creek or in the Brazos River is not of concern to plant safety because station cooling water is obtained from SCR. Thus, low flow considerations are significant in terms of successful over-all plant operations, but are not safety-related.

A study by the Texas Water Development Board indicated that from 1891 to 1960 Texas experienced 11 significant drought periods of varying severity and areal extent. Their ranking and time of occurrence are listed below:

1.	Most Severe	1954-1956
2.	Second	1916-1918
3.	Third	1909-1912
4.	Fourth	1901
5.	Fifth	1953
6.	Sixth	1933-1934
7.	Seventh	1950-1952
8.	Eighth	1924-1925
9.	Ninth	1891-1893
10.	Tenth	1937-1939
11.	Eleventh	1896-1899

The 1954-1956 drought was the most severe and was immediately preceded by the fifth and seventh ranked droughts, comprising a continuous series of years of rainfall deficiencies. This series, 1950 through 1956, comprises the most intense seven-year drought period that the State as a whole has experienced within the 70-year period of rainfall records. Dendrochronological studies in the southwestern part of the United States suggest that the 1950-56 drought period ranks among the most severe droughts of the past 400 years. Results of the studies indicate that records of stream flows during the 1950-56 period provide a basis for evaluation of the dependable amounts of water which can be obtained from existing and proposed reservoirs [37].

Detailed analysis of performance of SCR under the critical drought conditions of 1950 through 1956 [25] indicates a potential need for diversions from Lake Granbury ranging from 52,450 acre-feet per year. Of these amounts, an estimated 26,400 acre-feet per year would be returned at a steady rate to Lake Granbury in order to maintain proper balance of water quality in the two reservoirs. Thus, the net volumes of water taken from Lake Granbury during the drought would average 33,100 acre-feet per year and would range from a minimum of 26,050 acre-feet per year to a maximum of 38,260 acre-feet per year.

Substantially more than the required amounts will be available to SCR from Lake Granbury under terms of an existing agreement with the Brazos River Authority. This agreement covers total use from Lake Granbury and/or Lake Possum Kingdom of 70,000 acre-feet per year. The dependable yield of Lake Granbury [26] has been evaluated as at least 69,200 acre-feet per year, exclusive of the additional yield which could be made available by releases from Lake Possum Kingdom. The 70,000 acre-feet per year of potential supply is more than adequate to provide the necessary net diversions to SCR, plus anticipated requirements of other facilities which might also draw on Lake Granbury.

As a further check on the adequacy of the basic water supply for CPNPP, additional yield studies were carried out for Lake Granbury and Possum Kingdom Reservoir based on the years 1950-1957 and the following assumptions:

1. Historical inflows to Possum Kingdom Reservoir during the years in question were reduced to reflect:

    a. Total exclusion of runoff that originated above Hubbard Creek Dam, White River Dam, Salt Creek Dam, and Millers Creek Dam. These are the projects which either have been completed since the drought years or are expected to be completed in the foreseeable future.

    b. Maximum utilization by the City of Abilene of the increase in diversion rights on the Clear Fork of the Brazos, granted by the Texas Water Rights Commission since the drought years.

2. Releases of water from Possum Kingdom Dam for generation of hydroelectric power were reduced to a rate of 50,000 acre-feet per year, as compared with an average of approximately 350,000 acre-feet per year during the years of the study.

3. Runoff originating above Lake Palo Pinto was excluded from inflows to the Brazos between Possum Kingdom and Lake Granbury.

4. Historical losses of water in transit between Possum Kingdom and the site of Lake Granbury were assumed to still occur, although the releases from Possum Kingdom were substantially reduced.

5. Reservoir storage capacities were reduced to reflect predicted siltation to about the year 2006.

6. The studies were started with Lake Possum Kingdom assumed to be at the same elevation as actually experienced at the beginning of 1950, and Granbury was assumed to start at elevation 688.0, or five feet below the top of conservation storage.

7. The seasonal pattern of hydroelectric releases from Possum Kingdom was based on the actual pattern of such releases during the years of the study. The seasonal pattern of demand at Lake Granbury was based on the combined requirements of Squaw Creek Reservoir and the fossil-fueled power plants which will also derive their cooling water supply from the lake.

Under these conditions, which are believed to be highly conservative, the studies show that Lake Granbury would provide a firm yield of 70,000 acre-feet per year by utilizing only the upper 51 percent of the available conservation storage volume.

2.4.11.2 Low Water Resulting From Surges, Seiches or Tsunamis

Not applicable (See Sections 2.4.5 and 2.4.6).

2.4.11.3 Historical Low Water

The extreme variability of flow in the Brazos River is depicted through a flow probability curve (Figure 2.4-24), which shows that the average discharge of 1,555 cfs at gaging station 8-0910 is equalled or exceeded only about 17 percent of the time [27]. This flow is modified by regulation of water by upstream reservoirs which tend to decrease the variability. The impact that upstream control has had upon flow extremes is indicated from data which show that the Brazos River was known to dry up completely before construction of Possum Kingdom Reservoir and from Figure 2.4-25 which shows the lessening of annual flood events subsequent to Possum Kingdom Reservoir.

Squaw Creek has not been gaged long enough to allow a direct measure of flow variability, but indirect generalization of variability is gained by comparison with the Paluxy River. A flow probability curve for the Paluxy River is illustrated in Figure 2.4-25, which shows that the average discharge of 70.8 cfs was exceeded only about 11 percent of the time. Since the SCR catchment size is only about 16 percent that of the Paluxy watershed at gaging station 8-0915, this variability will be much more pronounced. Thus, inflow from Squaw Creek will be extremely variable.

Lake Granbury and SCR will serve to regulate the naturally variable flows and provide suitable minimum water levels on a dependable basis.

The Lake Granbury yield discussed in 2.4.11.1 above is based on not drawing that reservoir below elevation 675.0 [26]. The normal operating level in SCR will be held not less than elevation 770.0 feet.

2.4.11.4 Future Control

Development of additional control on the upriver sections of the Brazos River is possible; an initial study of potential reservoirs by the Brazos River Authority [40] identified three possible sites between Possum Kingdom Reservoir and Lake Granbury. These sites are briefly outlined on Table 2.4-3. Any one of these possible developments would increase storage availability and should strengthen water availability.

Downstream of DeCordova Bend Dam there is a possible reservoir site at Bee Mountain. The water at maximum level would be elevation 609 feet [40] and would impound the Brazos River

channel almost to DeCordova Bend Dam. It would be technically feasible to withdraw water from that lake also, offering an additional source of makeup water.

Under the Water Rights system of the State of Texas, issuance by the Texas Water Rights Commission of the permit to build and operate SCR precluded any further significant development and control upstream on Squaw Creek watershed itself.

2.4.11.5 Plant Requirements

The single source of safety-related cooling water and the ultimate plant heat sink for the Comanche Peak Nuclear Power Plant (CPNPP) is the SSI. This reservoir contains a volume of water, including evaporative contingency, that is sufficient to provide cooling for a period of over 30 days without makeup to safely limit the effects of an accident in one unit, to permit the safe shutdown of the other unit, or simultaneous shutdown of both units and maintaining them both in a safe shutdown condition. The available volume of water is determined during postulated 100-yr drought conditions as specified by NRC Regulatory Guide 1.27 and after a postulated 40 years of sedimentation. The minimum safety-related cooling water flow required for the two units during accident operation is 34,000 gpm, which represents the cooling water requirements of 17,000 gpm for post-LOCA cooling of one unit and 17,000 gpm for safe shutdown of the other unit. Expected safety-related cooling water flow is 51,000 gpm, which represents 17,000 gpm for post-LOCA cooling of one unit and 34,000 gpm for safe shutdown of the other unit. Plant water requirements for all modes of operation are given on Figures 2.4-26, 2.4-27, 2.4-28, and 2.4-29.

Cooling water for both units is withdrawn from the SSI and delivered by four 17,000-gpm-capacity station service water pumps enclosed in a seismic Category I structure, the Service Water Intake Structure. The Service Water Intake Structure sump descends to elevation 755 ft 0 in, and the service water pump impeller blades descend to elevation 758 ft 0 in. Each pump is designed to operate with a minimum submergence requirement of 4 feet - 6 inches above the bellmouth flare (El. 757 ft). As a result, a minimum water elevation of at least 761 ft 6 in is necessary for service water pump operation. The minimum water elevation, considering no makeup of water and the most severe period for evaporation described in Section 2.3.1.2.10, is 766 ft 4 in. at 30 days and 765 ft. 4 in. at 39 days. Therefore, substantial margin for submergence is provided.

Cooling water is returned to the SSI through the Service Water Discharge Structure. Water from this structure enters the SSI at a point remote enough from the Service Water Intake Structure and at a velocity high enough to ensure adequate mixing, dispersion, and evaporative cooling of the effluent. The station service water pumps, Service Water Intake Structure, and Service Water Discharge Structure are described in Section 9.2.1.

The SSI is formed from an inlet of the Squaw Creek Reservoir (SCR) and is separated from the reservoir by a seismic Category I dam. The surface elevation of both bodies of water is a minimum 770 ft 0 in during normal operation. The seismic Category I dam, however, will maintain the SSI at a surface elevation of 769 ft 6 inches in the event of an accident involving water loss from the SCR. The ultimate Heat Sink is described in Section 9.2.5.

The SSI is constructed specifically to serve as the ultimate heat sink for the CPNPP. Except for a backup source for auxiliary feedwater (Section 10.4.9.3), there are no other uses of this water during accident and safe shutdown operations. Water rights to the SSI are guaranteed by the Texas Water Rights Commission. For use of water near the plant site, see Subsection 2.4.13.

2.4.11.6 Heat Sink Dependability Requirements

The source of plant cooling water for the CPNPP is the SCR. This reservoir is formed by a dam structure extending across the Squaw Creek and creating a cooling water impoundment in the Squaw Creek Basin behind it (see Figure 2.4-4). The impoundment is normally supplied with makeup water from Lake Granbury. In addition, water is exchanged, as necessary, between Lake Granbury on the Brazos River and the SCR to reduce total dissolved solids levels.

The single source of safety-related cooling water is the SSI, which functions as the ultimate heat sink for the CPNPP. The SSI is formed from an inlet of the SCR and separated from it by a seismic Category I dam. A canal connects the SSI with the SCR and maintains an equal water level between the two bodies of water. The seismic Category I dam and canal maintain the water level of the SSI at 769 ft 6 inches in the event of accidental water loss from the SCR. Waterflow through the canal will stop at this elevation. A simultaneous failure of both the SCR dam and the SSI Dam is considered unlikely since the SSI Dam is a seismic Category I structure.

Cooling water for normal plant operation is withdrawn from the SCR by eight 275,000-gpm-capacity circulating water pumps. Each pump is a 25-percent-capacity unit, and all pumps are located in the Circulating Water Intake Structure. Each pump has impeller blades which extend to elevation 758 ft 0 in and to a minimum submergence requirement of 12 ft. The circulating water pumps are not required for plant shutdown.

Cooling water is returned to the SCR via the Circulating Water Discharge Structure. The structure discharge is located at an adequate distance from the Circulating Water Intake Structure to ensure sufficient water mixing and evaporative cooling.

Safety-related cooling water is withdrawn from the SSI by four 17,000-gpm-capacity service water pumps. All pumps are located in the Service Water Intake Structure, a seismic Category I building. Safety-related cooling water is returned to the SSI through the Service Water Discharge Structure. The discharge structure is located at a sufficient distance from the Service Water Intake Structure to ensure adequate water mixing and evaporative cooling.

The minimum water level of both the SCR and the SSI during normal plant operation is 770 ft 0 in. This water level is adequate for both circulating water pump and station service water pump operation. During postulated 100-year drought conditions, and after 40 years of sedimentation, the SSI is determined to have 284 acre-ft of water.

Figures 2.4-26 through 2.4-29 describe cooling water requirements for the various modes of plant operation. Section 9.2.5 discusses design bases and safety functions of the SSI as the CPNPP ultimate heat sink.

The anticipated loss from the SSI caused by evaporation is 92 acre-feet. The seepage and drift loss is negligible in comparison to the evaporation losses. Instrumentation, which is read in the Control Room, is provided to measure the SSI water level as shown on Figure 9.2-1. An alarm is provided in the Control Room for low SSI water level and high differential level across the travelling screens. The low level alarm is set at or above the normal low SSI water level as desired by the operator as an aid for lake level management. The SSI will be dredged as required.

The CPNPP design of the SSI as the single ultimate heat sink complies with the intent of NRC Regulatory Guide 1.27 as discussed in Chapter 1, Appendix 1A(B).

The SSI is the source of fire protection storage tank emergency fill water. SSI level changes caused of the Fire Protection System are insignificant since the system is used infrequently and for periods of short duration. Refer to Section 9.5.1 for a description of the Fire Protection System.

Cooling water is withdrawn from the SSI at the Service Water Intake Structure. Elevations of intake structure pump deck and channel floor are established with due consideration for pump minimum submergence requirements and reservoir level fluctuations. For elevations and layouts of Service Water Intake Structure components, see Section 9.2. Plant water requirements for various modes of operation are given in Figures 2.4-26, 2.4-27, 2.4-28, and 2.4-29.

2.4.12 DISPERSION, DILUTION, AND TRAVEL TIME OF ACCIDENTAL RELEASES OF LIQUID EFFLUENTS IN SURFACE WATERS

2.4.12.1 Introduction

This section provides a conservative analysis of a postulated accidental release of radioactive material in surface waters adjacent to the site. The postulated release was assumed to occur due to an accidental rupture of the waste holdup tank which is located in the Auxiliary Building near the Containment Building.

The volume of the tank is 30,000 gallons and at the time of rupture it was assumed that the tank was 80 percent full. The assumed concentrations of radionuclides in the tank at the time of rupture are given in Table 2.4-20.

It was conservatively assumed that all the liquid radwaste (24,000 gallons, or 7.36×10^{-2} acre-feet) is spilled into Squaw Creek Reservoir. Minimum dilution in Squaw Creek Reservoir would occur at minimum pool elevation 770.00 feet (msl), corresponding to a storage volume of 135,062 acre-feet. Assuming complete mixing, the minimum dilution factor is 135,062/(7.36 x 10-2) or 1.84 x 106.

The instantaneous concentrations in Squaw Creek Reservoir are calculated by dividing the concentrations in the tank by the dilution factor. Due to the decay characteristics of the radionuclides, most concentrations decrease with time, however, some radionuclides build up in the reservoir as decay products. A computer code, RADIOISOTOPE, described in Appendix 15B Section 15B.6, was used to calculated the decayed concentrations. The concentrations of each radionuclide in Squaw Creek Reservoir at the end of 1 day, 1 month and 1 year is shown in Table 2.4-21. Since the intent of the analysis is to demonstrate that the concentrations of radionuclides in the reservoir do not exceed the effluent concentrations for unrestricted areas given in 10CFR20 Appendix B, the total effluent concentration fraction is also given for each of the above time periods. The results demonstrate that the water volume of the reservoir provides sufficient dilution, and that most of the activity would decay away after one month.

The water usage pathways involving Squaw Creek Reservoir indicate that a portion of the reservoir inventory may be transferred to Lake Granbury and Lake Whitney. This transfer would

provide for additional dilution of radionuclides due to the added water volumes, and it is expected that the concentrations of radionuclides in Lake Granbury and Lake Whitney would be much lower than those in Squaw Creek Reservoir. The flow pattern which exists among these bodies of water, and the overall potential for further dilution of Squaw Creek Reservoir concentrations provided by those other two lakes is more fully addressed in Appendix 11A.

2.4.13 GROUNDWATER

The investigation of groundwater features included:

1. A review of groundwater information obtained from public agencies and from literature.

2. A field inventory of all wells used for water supply within two miles of the site and reservoir fringe.

3. A review of municipal, industrial, and irrigation wells within 20 miles of the site.

4. Measurements of water levels in several exploratory borings which were drilled to obtain geologic, geohydrologic, and foundation data.

5. The evaluation of the probable influence SCR and CPNPP will have on the quality and piezometric level of groundwater in the site vicinity.

[General References 29, 30, 31, 32].

2.4.13.1 Description and On-Site Use

2.4.13.1.1 General Groundwater Features

The CPNPP site is located within the Great Plains Physiographic Province, about 4 1/2 miles north of Glen Rose, Texas, and approximately four miles west of the Brazos River. The power plant site is on a relatively narrow ridge which trends east-southeast and is flanked on the north and south by the SCR (Figure 2.1-2). Topography in the site vicinity ranges from slightly undulating to stair-stepped. Ground surface near the site ranges from elevations 600 to 700 feet (Mean Sea Level Datum) in valleys to elevations 900 to 1000 feet on ridges. The Brazos River channel a few miles east of the site is at approximate elevation 560.

The site is underlain by a sedimentary rock sequence which, at the surface, has been weathered to a clayey, silty, sandy overburden soil with some rock fragments. Overburden on the ridges and slopes ranges in thickness from a few inches to a few feet and rock outcrops are common. The soils and much of the rock are relatively impermeable. In valley bottoms, rock is overlain by a combined thickness of alluvial sediments and underlying residual soil. Total overburden ranges from 10 to 15 feet in depth. The sediments are of minor thickness and vary from slightly permeable to essentially impermeable.

In the site area, including the floodplain, infiltration into subsurface formation is retarded because of low permeability of the strata. Most precipitation flows across the surface and drains away as surface runoff or returns to the atmosphere by evaporation and transpiration. Water-bearing strata in the area are mainly recharged in their outcrops areas.

Data from a nearby gaging station on the Paluxy River indicate that the net surface runoff and base flow (which is derived from shallow groundwater) together total some two inches annually. Evaporation from a free water surface, such as a lake, is approximately 72 inches per year [33].

Most of the groundwater in the site region occurs in bedrock. Some water does exist in shallow floodplain alluvium in stream valleys, but is not withdrawn for use. Regional bedrock aquifers in order of increasing age are the Paluxy, Glen Rose and Twin Mountains formations, of the Comanche series, Cretaceous age [34]. Locally, CPNPP and SCR are on the Glen Rose outcrop, which, in turn, is underlain by the Twin Mountains Formation. The Paluxy Formation is absent at the CPNPP location, and within the limits of the reservoir; the Glen Rose Formation is the upper stratigraphic unit exposed in these areas.

The structure, stratigraphy, and composition of the three strata are described in detail in Section 2.5.1. A geologic cross section representing the approximate orientation of these strata near the site is shown on Figure 2.5.1.2-5 (see upper right portion of cross section). The approximate limits of formation outcrops in the counties surrounding the site are shown on Figures 2.4-30, 2.4-31 and 2.4-32.

The Paluxy, Glen Rose, and Twin Mountains formations are large in area. Their outcrops form a strip of land tens of miles wide that extends south from Central Oklahoma, strikes westward in Central Texas, and extends into Mexico [35]. The formations in the site region dip eastward.

The Twin Mountains and Paluxy formations are principally sandstone, but also have shale, limestone, claystone, and siltstone inclusions. Limestone is the dominant rock type within the Glen Rose Formation, but it also contains significant quantities of shale, siltstone and claystone. In these formations, groundwater percolates slowly along bedrock joints and fractures, and through interstices in the rock fabric.

The Twin Mountains is the only relatively productive bedrock zone in the site vicinity. The Paluxy Formation has nominal pumpage near the site and the Glen Rose Formation yields very little water in the site area and is usually less productive than the other formations.

At distances of 20 to 50 miles downdip from the outcrop, the groundwater becomes saline and the formations lose their importance as sources of fresh water [36]. The three formations are discussed individually in succeeding sections.

2.4.13.1.2 Twin Mountains Formation

A detailed description of the lithology, stratigraphy, and structure of the Twin Mountains Formation is given in Section 2.5.1. The formation is predominantly sandstone with subsidiary shale, claystone, siltstone, and limestone.

The principal origins of the groundwater within the Twin Mountains Formation are rainfall and streamflow occurring in the outcrop area (Figure 2.4-32).

Downdip from the outcrop, groundwater in the Twin Mountains Formation is confined by fine-grained materials in the overlying Glen Rose Formation. Hydrostatic pressure in the Twin Mountains is great enough to create static water levels which rise above the formation and, sometimes, great enough to cause flowing wells. The piezometric level measured in this

formation at the site in Boring P-10 is approximately elevation 670, about 60 feet above the formation surface.

Groundwater is discharged in the outcrop area by evapotranspiration and localized springs and seeps along drainages incised below the water table. Downdip (where the formation is confined, such as at CPNPP site), natural discharge is limited to a minimal upward movement into overlying formations.

Although the Twin Mountains Formation is a moderately productive stratum in the site vicinity, two packer pressure tests of 60 feet of this rock in a boring at the CPNPP site did not result in water take. This test indicates that there are essentially impermeable rock zones within this formation.

2.4.13.1.3 Glen Rose Formation

This formation is predominantly limestone, but significant amounts of shale, siltstone and claystone are also present. A full description of the geology of the Glen Rose Formation is presented in Section 2.5.1.

The principal origins of groundwater in the Glen Rose Formation are rainfall on the outcrop area and minor seepage from the overlying Paluxy Formation and underlying Twin Mountains Formation. The Glen Rose Formation outcrop area is shown on Figure 2.4-31.

CPNPP and SCR is constructed on the Glen Rose Formation; thus the character and rate of groundwater movement in this formation is of special interest. The Glen Rose limestones are essentially impermeable due to slight amounts of argillaceous impurity and are thus resistant to solution effects. Open voids, caverns, joints, collapse features, and frequent fractures common to some limestones are notably absent in the Glen Rose Formation at the site; therefore, the groundwater moves very slowly through and into the Glen Rose Formation, principally through the joints and fractures that do exist. Occasional isolated sand lenses also contain groundwater.

Detailed examination of cores from borings revealed no solutioning features and minimal fractures. Packer pressure tests in the Glen Rose Formation performed in most borings at the station, SSI Dam and spillway, and Squaw Creek dam and spillway incurred essentially no “water take” in rock beneath the upper, usually thin, weathered zone. Pressure tests were performed within the rock in many borings to evaluate jointing and/or the absence of solutioning features and to evaluate general permeability characteristics. Tests employed single and double packers and gage pressure ranging to 80 psi. The results of packer tests are presented on Table 2.5.6-1. Only zones at a depth range of 194 feet to 214 feet (elevation 649.04 to 629.04 feet) recorded any water loss. Upon review of the Log of Boring for Boring P-10, the cause of the water losses can be attributed to a zone of sandstone and sand lenses.

Drill water occasionally was lost while drilling through the upper weathered zone. A relatively thick pervious zone was encountered in Borings DI-8 and DI-9, approximately 1 1/4 miles southeast of the station. These borings are at the middle to outer extremity of a peninsula which will form the south abutment for Squaw Creek Dam. There, a large amount of drill water was lost while advancing Boring DI-8 to 56 ft and DI-9 to shallower depth through some zones of weathered, fractured rock. Indications were that water loss occurred principally within the upper 20 to 30 feet of each boring. There is no evidence of solutioning in the zone of water loss.

Boring DI-10, drilled farthest from the peninsula point, incurred no drill water loss, thereby indicating that conditions improve southward along the peninsula.

Northwest of the site, where the Glen Rose Formation is covered by outliers of the Paluxy Formation, a few domestic water wells are completed in the Glen Rose Formation. These wells produce potable water and they are reliable during droughts; this reliability is due to the slow release of groundwater to the Glen Rose Formation from the overlying Paluxy Formation. Elsewhere, wells completed in the Glen Rose Formation are often unreliable during droughts.

In its outcrop areas, the Glen Rose Formation discharges water naturally through springs and seeps. In the confined portions of the formation, when differential hydraulic pressures occur, there is very minor transfer of water into overlying and underlying formations from the Glen Rose Formation.

2.4.13.1.4 Paluxy Formation

This formation is predominately sandstone, but shale, siltstone, claystone and limestone are also present. A detailed description of the lithology, stratigraphy and structure of the Paluxy Formation is given in Section 2.5.1. The Paluxy Formation is not present at the CPNPP and SCR locations.

Recharge to the Paluxy Formation occurs in the outcrop areas as a result of infiltration of rainfall and of seepage from streams.

It also receives water from water-bearing units under greater hydraulic head which adjoin the Paluxy Formation. Figure 2.4-30 shows the outcrop area of the Paluxy Formation. South of the CPNPP site, across the Paluxy River, the formation is confined by overlying fine-grained bedrock strata. These strata are not of significance to CPNPP.

Groundwater discharges from the Paluxy Formation as springs and seeps in some outcrop areas. Where the formation is confined, there is limited water movement into overlying confining units if those units are at lower hydraulic head.

2.4.13.1.5 Onsite Water Table

Following the subsurface exploration program, a number of the borings were used to determine water levels. Of these borings, P-10 was completed in the Twin Mountains aquifer; the piezometric water level in that boring is elevation 670. The remainder of the borings monitored for groundwater were completed in the Glen Rose Formation. Static water levels observed in these borings are presented in Figure 2.5.5-77 and range from elevation 749 to 830.

As indicated in Section 3.8.5.1.5, groundwater is not expected to reach higher than elevation 775.0 feet. All piezometric levels recorded on Figure 2.55-77 were measures of perched water in the upper zone of the Glen Rose Formation in the immediate area of each piezometer. The resulting elevation range of 749 to 830 feet is attributed to surface run-off and not a true measure of permanent groundwater in the Formation.

Water levels in the Glen Rose Formation are expected to show some variation in response to seasonal climatic changes; those in the Twin Mountains Formation will be much less influenced by seasonal conditions because of the distance from the recharge area.

Piezometers which measured the levels recorded in Figure 2.5.5-77 were installed during preliminary design work at the site, before the site was excavated to plant grade (elevation 810). A permanent system of piezometors has been installed in order to monitor ground water levels at the site. This program is described in Section 2.5.4.13. A Groundwater Monitoring Program is established and incorporates several sentinel wells in various locations throughout the plant site for prompt identification of potential radiological release source locations.

2.4.13.1.6 Water Quality

Potable groundwater occurs in the Twin Mountains, Glen Rose and Paluxy formations. The results of chemical analyses of groundwater obtained from wells drawing from these formations are summarized in Table 2.4-22. (Well locations are shown on Figure 2.4-33).

Water in the Twin Mountains Formation is a sodium bicarbonate type with a dissolved solids content varying generally from 200 to 900 mg/1. In and near the outcrop areas, Twin Mountains water is used for irrigation. At the site, however, the water is unsuitable for irrigation due to the local soil conditions and the increased sodium content of the water. The results of physical and chemical analyses performed on the samples taken from the production and observation wells during the years of 1975-76 are presented and discussed in the Environmental Report/Operating License Stage (ER/OLS). The sodium content of the water samples ranges from 100 to 150 mg/1, with dissolved solids content varying from 300 to 500 mg/1. The temperature of groundwater follows the seasonal atmospheric average temperature values, and ranges from 20° to 26°C (68° to 79°F). The conductivity values vary between 550 to 1300 mhos.

The quality of water obtained from the Glen Rose Formation is variable; in localized areas it is not potable. Northwest of the site, water is produced from the Glen Rose Formation where it is capped by an outlier of Paluxy Formation. The analysis from well No. 48 is an example of the water quality obtained from this area. The chemical analysis from well No. 48 is presented in Table 2.4-22.

The Paluxy Formation is tapped by some domestic water wells south of the Paluxy River. The chemical analysis of water from a well five miles east of Walnut Springs in Bosque County is shown in Table 2.4-22. This well is located close to the outcrop area of the Paluxy Formation, where the water is typically a hard calcium bicarbonate type. Further downdip, the water becomes a progressively softer, sodium bicarbonate type.

2.4.13.1.7 Onsite Water Uses

Groundwater usage on the site is presented in Table 2.4-23. Continuous usage will be about 127 gpm and the peak plant requirement is estimated to be 330 gpm. Alternate source of supply of water for this usage will be from the surface water pre-treatment system.

2.4.13.2 Sources

2.4.13.2.1 Regional Use

1. Paluxy and Glen Rose Formations

   Groundwater is pumped from the Paluxy and Glen Rose formations by small-capacity wells for livestock and rural domestic use. Pumpage is not metered within the region.

Withdrawals from both formations, however, are estimated to be less than 100 acre-feet per year. Water extraction from these formations has no identifiable effect on regional piezometric levels. Groundwater use is not expected to increase significantly in the future because these formations are poor aquifers and will probably not be developed for water supply by either cities or industries or for large scale irrigation. More favorable water supplies are available from surface sources or from the Twin Mountains Formation.

The regional movement of water in the Paluxy and Glen Rose formations is downdip to the east. The hydraulic gradient in the Paluxy is about 20 feet per mile in downdip areas. The rate of regional groundwater movement is estimated to be on the order of one foot per day or less in the Paluxy Formation.

Because groundwater in the Paluxy is used only for domestic and livestock purposes in rural areas, wells are usually of small pumping capacity, typically under 10 gallons per minute or less. It is estimated that maximum potential well yield in the region is probably under 50 gallons per minute.

There are few wells withdrawing water from the Glen Rose Formation. This formation typically is not capable of supplying more than about 10 gallons per minute to wells. Water levels in the Glen Rose fluctuate in response to precipitation, and some wells in the Glen Rose are reported to have failed during certain droughts.

Generally, water use from the Paluxy and Glen Rose formations is small and individual wells are of very limited capacity. The aquifers are variable in their hydraulic characteristics and also in the quality of water they yield. As a result, no significant development of these sources of groundwater is anticipated.

2. Twin Mountains Formation

Prior to 1880 there was relatively little groundwater development from this formation. Since the early 1900's pumpage has increased to include wells from municipal, industrial and irrigation purposes.

The Twin Mountains Formation is the primary source of groundwater used in the region although this use is not extensive.

Principal wells in the area, i.e., public supply, irrigation and industrial, which are within 20 miles of the site, are listed on Table 2.4-24 and locations are shown on Figure 2.4-33. Texas Water Development Board studies [37] indicate that current annual pumpage from the Twin Mountains Formation is about 100 acre-feet per year within a 20-mile radius of the site. By the year 2020, the total pumpage is projected to be not more than 200 acre-feet per year.

The groundwater movement is downdip to the east (Figure 2.4-34), at a rate of approximately two feet per day. The current piezometric gradient is about 20 feet per mile. Permeability of the formation ranges from 90 to 240 gallons per day per square foot [34].

The recharge area (outcrop area) is shown on Figure 2.4-32. Because the site is near the recharge area and because of the relatively small projected amount of future pumping, no

significant change in groundwater level is expected in the site vicinity during the life of the plant.

2.4.13.2.2 Local Use

All water wells within a two-mile radius of the site were inventoried. In addition, information was gathered on water wells in and adjacent to the planned impoundment. The locations of wells in the vicinity are shown on Figure 2.4-35. The well data are listed on Table 2.4-25. All wells in the site vicinity are of small capacity and are used for individual rural home and livestock requirements. With few exceptions, all are deep wells, completed in the Twin Mountains aquifer.

To the north of the site, a few wells are completed in the Glen Rose Formation. The presence of adequate and reliable supplies of groundwater in the Glen Rose Formation is dependent on a sandstone cover (the Paluxy Formation). This sandstone cap results in prolonged percolation to the Glen Rose and results in relatively high water levels, even during drought conditions.

Data collected on local water levels has permitted mapping of the Twin Mountains piezometric surface in the site area; this map is shown on Figure 2.4-36, which is more detailed than the regional map, Figure 2.4-33.

Two production wells (PW-1 and 2), and three observation wells (OB-1, 2 and 4) are constructed onsite and their locations are shown in Figure 2.4-37. Observation well No. 3 was an existing well in the plant property. All these wells tap water from Twin Mountain Formation. Pumping tests were run PW-2 as the pumped well and PW-1 as observation well. From these tests a coefficient of transmissibility of 12,000 gpd/ft and a storage coefficient of 0.00005 were calculated. The two production wells (PW-1 and 2) along with two others on-site were plugged and capped in 2013.

Using these aquifer characteristics and a pumping rate of Q = 100 gpm, a series of drawn-down curves in relation to distance and time are plotted (Figure 2.4-38).

To satisfy water demands during construction, pumpage has occurred in the production wells. The pumpage rates for 1975 are presented in Table 2.4-26. These figures show that the average pumping rate was about 150 to 160 gpm. The hydrographs of observation wells during this pumpage are shown in Figure 2.4-39. The early measurements made in OB-4 indicate an abnormally high water level and sudden change in the level from August to September. This abnormality and change may be due to incomplete development of the well after completion. Each of these wells is sampled by pumping once a month as part of the quality monitoring program with the exception of Production Well Numbers 1 and 2 which were no longer sampled after being plugged and capped in 2013. Therefore, OB-4 may have been further developed by the pumpage and by the removal of any obstruction.

The average effect on the water levels of the observation wells due to plant pumpage is approximately nine feet. The hydrograph of the observation wells indicates that water levels from September to December have remained fairly constant. This constancy begins after approximately 200 days of pumpage, which conforms to the distance draw-down curves where the greatest amount of draw-down occurs in the first 180 days.

Operational pumpage of the plant will be 127 gpm on continuous basis. The peak plant requirement is estimated to be 330 gpm for a short time period. The alternate source of water

supply is the surface water pre-treatment system taking raw water from Squaw Creek Reservoir. This minimizes the effects of operational pumpage on draw-down. The nearest boundary line of the project area to the production wells is more than one mile. From the draw-down curves presented in Figure 2.4-38, it can be estimated that draw-down due to 34.5 gpm continuous pumpage during the life of the plant (40 years) will not be more than 2.5 feet at the boundary line. In case of 330 gpm peak pumpage rate, the temporary draw-down will be 3.3 feet for one day pumpage and 7.25 feet for three days pumpage at the same location.

Operational pumpage from wells in the owner controlled area followed a stepwise trend. The first six years 1975 to 1980 pumpage averaged 145 gpm. From 1981 to 1990 (years leading up to and including Unit 1 start-up) pumpage averaged 16 gpm. From 1991 to 2011 production well pumpage averaged 23.2 gpm. Since 2012, operational pumpage from groundwater dropped to less than 1 gpm when Somervell County Water District became the sole supplier of potable water.

Historical groundwater levels around the plant site can be estimated from the records of four Texas Water Development Board observation wells in Somervell County. The locations of these wells are also shown in Figure 2.4-37 and their records are presented in Table 2.4-27. The records indicate a fluctuation of levels and also localized cones of depression.

Based upon the geohydrologic characteristics at the site, it is estimated that the piezometric level in the Twin Mountains Formation will be depressed locally due to pumpage from the production wells, but without adverse effect on the station or the existing wells withdrawing water from the formation. Within the Glen Rose Formation, water levels will not be affected due to this pumpage.

All wells and borings in the impoundment area are grouted and sealed to insure no direct intrusion of reservoir water into subsurface aquifers.

2.4.13.3 Accident Effects

2.4.13.3.1 Introduction

This section provides a conservative analysis of a postulated accidental release of radioactive liquid at the surface of the site. The postulated release is assumed to occur due to an accidental rupture of the floor drain tank which is located in the Auxiliary Building near the Containment Building. This tank is located inside a Category I building with a drain collection system.

The volume of the tank is 30,000 gallons and at the time of rupture it was assumed that the tank was 80 percent full. The assumed quantities of radionuclides in the tank at the time of rupture are given in Table 2.4-20A. It is further assumed that all the liquid gets outside the Auxiliary Building unimpeded and no action is taken to contain or clean up the water spill.

The Auxiliary Building is founded in the Glen Rose limestone which is an essentially impermeable formation (see section 2.4.13.1.3). No ground water was encountered during excavation into the Glen Rose limestone for the plant foundations. However, during design validation efforts, it was determined that perched water may exist at elevations higher than 775'-0". This condition was created by the excavation and backfill process associated with buried piping ductbanks and the service water intake structure when backfill was placed using pervious material. This arrangement allows surface runoff to be trapped in the pervious zone

(backfilled area) thus raising the local water level (called perched water level) above elevation 775'-0". This ground water therefore, is not hydraulically connected to the Twin Mountains aquifer which is approximately 200 feet below plant grade. Design Basis groundwater level for lateral forces on the plant structures is conservatively taken as 810'-0" except at the Service Water Intake Structure. It is expected that the ground water gradient will be from the reservoir toward the plant site, thus restricting the movement of any released liquids above elevation 810'-0" to predominantly vertical flow. A buildup in the ground water level through percolation of rainfall over the plant site into the essentially impervious limestone is considered unlikely. Therefore, because mounding due to percolation is highly unlikely, it is correspondingly improbable that recharge in the plant area would increase the potential for outward horizontal flow toward the reservoir. If the released liquid could travel horizontally through the Glen Rose limestone, it would enter Squaw Creek reservoir. The ability of the surface water regime to dilute and disperse such releases is discussed in Section 2.4.12.

In order to evaluate the effect of a postulated accident on the Twin Mountains aquifer, a conservative mathematical model with simplifying assumptions was used to model the dispersion of the liquid through the Glen Rose limestone down to the top of the Twin Mountains aquifer.

2.4.13.3.2 Description of the Model

The dispersion and decay of the radionuclides within the Glen Rose limestone was evaluated using the model described briefly below.

The governing equation employed in this one-dimensional dispersive and convective model may be written as follows:

$$\frac{\partial}{\partial t}(R^j C_j) + \frac{\partial}{\partial x}(UC_j) = S^j + \frac{\partial}{\partial x}\left\{ Dx^j \frac{\partial C_j}{\partial x} \right\} - R\lambda^j jC_j$$

where

C_j is the concentration of the chemical species j;

R^j is the retardation factor for the species j, comprising adsorption, ion exchange, precipitation, colloid filtration and irreversible mineralization;

U is the groundwater velocity in the x-direction;

S^j is the source term for chemical species j;

D_x^j is the dispersion coefficient for species j is the x direction;

λ^j is the decay coefficient for species j (also given by $1n2/T^{1/2}$ where $T^{1/2}$ is the radionuclide half-life);

x is the distance in the x-direction; and

t is the elapsed time.

This governing equation is solved by a numerical model which employs a partly implicit solution procedure to predict chemical species concentrations as a function of space and time.

The discretized form of the governing equation is obtained by integration over control volumes defined by a numerical grid set up for the region of interest.

2.4.13.3.3 Selection of Parameters

1. Initial and Boundary Conditions

Initial and boundary conditions must be supplied to the numerical model in order to complete the mathematical specification of the problem. The initial conditions designate the distribution of radionuclides over the entire solution domain at the commencement of the analysis. In this problem, zero concentrations were specified everywhere initially.

Boundary conditions represent variations of the concentrations, the concentration fluxes, or a combination of these, at the boundaries of the domain. In the case being considered, the lower boundary condition was specified as a zero gradient boundary. That is, the radionuclide concentrations just within the upper part of the Twin Mountains aquifer were

considered to be identical to those just within the lower part of the Glen Rose limestone; i.e., the radionuclides are transported by convection alone. The upper boundary coincides with the base of the storage tank. The upper boundary condition was therefore the radionuclide source of the concentration contained in the tank.

2. Reduction Factor

The reduction factor was conservatively assumed to be equal to 1, implying that no retardation in movement or interaction between radionuclides and soil occurs.

3. Initial Flow Velocity

The initial flow velocity of radionuclides out of the base of the tank is limited by the capacity of the soil to absorb the flow; i.e., the saturated vertical permeability of the Glen Rose limestone. The permeability value was estimated from packer-test data to be:

$k = 2.8 \times 10^{-2}$ ft/day.

4. Dispersion Coefficient

The equation given by Fried and Combarnous (43) can be utilized in the calculations:

$Dx = D_o [0.67 + 0.5(U_x d_{50}/D_o)1.2]$

where d_{50} is the mean particle size (ft), U_x is the groundwater velocity (ft/day), and D_o is the molecular diffusion in bulk water (ft^2/day). D_o is equal to approximately 9.7×10^{-4} ft^2/day. Letting the groundwater velocity go the zero, and changing units yields:

$D_x = 0.0004$ cm^2/minute

Another value reported for the soils similar in dispersion characteristics is the value given in Reference 44, which is:

$D_x = 0.0028$ cm^2/minute

Taking the geometric average of these two values as a conservative approximation of the dispersion coefficient yields:

$D_x = 0.001$ cm^2/minute = 1.6×10^{-3} ft^2/day.

5. Decay Coefficient

The decay coefficient, λ^j, is calculated from known half-life values for each of the radionuclides of concern.

6. Source Term

The source term, S^j, is calculated from the known curie content of the tank, and the volume of fluid within the tank, assuming that the entire base of the tank ruptures instantaneously.

2.4.13.3.4 Computation Results

The analysis showed that only one radionuclide, CS-137, penetrated the entire 150-foot depth of the Glen Rose Limestone to reach the Twin Mountains aquifer below. To illustrate the dispersion of the major radionuclides of concern, the results for those with the greatest release concentrations and longest half-lifes have been tabulated in Table 2.4-28. This table illustrates the maximum depth to which significant concentrations penetrate. Concentrations of less than 10^{-13} μ Ci/ml (2.83×10^{-15} Ci/ft^3) were considered insignificant.

CS-137 is shown to penetrate the entire 150 feet in 400 years; therefore, more detailed results are presented for this radionuclide in Table 2.4-29. This table shows the concentrations of CS-137 throughout the limestone as a function of time. This conservative analysis calculates the maximum concentration of any radionuclide anywhere in the groundwater to be 4.8×10^{-12} μ Ci/ml as a result of the postulated accident.

2.4.13.4 Monitoring or Safeguard Requirements

No planned releases to the ground water environment will take place at the plantsite. However a Groundwater Monitoring Program exists for early detection of inadvertent releases of radioactive material. Pertinent information is provided in Section 6.1 of the Environmental Report.

2.4.13.5 Design Bases for Subsurface Hydrostatic Loading

The lateral pressure (σ) caused by the groundwater at a given point is equal to the unit weight of water (γ) times the vertical distance from the water table to the point at which the pressure is computed (H):

$$\sigma = \gamma H$$

Uplift pressures are similarly computed as H, where H is the vertical distance from the water table to the surface on which the uplift is computed.

No ground water was encountered during excavation and construction of the plant structures. However, during design validation efforts it was determined that ground water or perched water may exist at elevations higher than 775'-0". Therefore, safety-related plant structures are conservatively designed for hydrostatic loads with the design basis ground water level at elevation 810'-0", except for the Service Water Intake Structure. Hydrostatic loads on the SWIS are determined with a design basis ground water level at elevation 793'-0".

There is no dewatering at the site during or after construction.

2.4.14 TECHNICAL SPECIFICATION AND EMERGENCY OPERATION REQUIREMENTS

The most adverse hydrological conditions detailed in the preceding sections do not affect the operation of safety-related facilities. Emergency procedures are required, however, if Squaw Creek Reservoir elevation exceeds 778 feet to ensure that the Electrical and Control Building is not flooded via the Circulating Water System. See Section 13.5 for a discussion of these procedures.

The maximum predicted normal SSI temperature for two unit full power operation is 102°F. Therefore, this is the initial condition assumed in the Station Service Water System (Section 9.2.1), Component Cooling Water System (Section 9.2.2), and Containment Heat Removal (Section 6.2.2) analyses and specified in the Technical Specifications.

The lowest normal SSI elevation is 770 ft. 0 in. as described in Section 2.4.11.5. This elevation is the initial condition assumed in the ultimate heat sink analysis described in Section 9.2.5.

Use - municipal and industrial

[redacted]

Morris Sheppard Dam and Possum Kingdom Reservoir

Location - on Brazos River at River Mile 687 in Palo Pinto County

Catchment - 13,310 sq. mi. contributing area.

Capacity - 600,000 ac-ft. (original capacity was 724,700 ac-ft., but sedimentation had reduced capacity to 600,000 ac-ft. by 1966.)

Owner - Brazos River Authority

Use - municipal, mining, irrigation, power and recreation

[redacted]

Palo Pinto Creek Dam and Lake Palo Pinto

Location - on Palo Pinto Creek in Palo Pinto County

Catchment - 471 sq. mi.

Capacity - 44,100 ac-ft.

Owner - Palo Pinto County Municipal District No. 1

Use - municipal and industrial

TABLE 2.4-1
PRINCIPAL DAMS AND RESERVOIRS UPSTREAM OF COX BEND

(Sheet 4 of 4)

[redacted]

DE Cordova Bend Dam and Lake Granbury

Location - on Brazos River at River Mile 542.5 in Hood County

Catchment - 15,451 sq. mi. contributing area.

Capacity - 155,000 ac-ft.

Owner - Brazos River Authority

Use - municipal, industrial, irrigational and recreational.

[redacted]

Reference: "Report 48, Dams and Reservoirs in Texas, Historical and Descriptive Information," Texas Water Development Board, 1967.

TABLE 2.4-2
PRINCIPAL DAMS AND RESERVOIRS DOWNSTREAM OF COX BEND

Whitney Dam and Whitney Reservoir (Lake Whitney)

Location - on Brazos River at River Mile 442.4 in Hill and Bosque Counties

Catchment - 16,930 sq. mi. contributing area

Capacity - 435,000 ac-ft.

Owner - U.S. Army Corps of Engineers

Use - Power and Flood Control

[redacted]

Note: Although there are many reservoirs downstream of Cox Bend on tributaries of the Brazos River, there are no other structures on the Brazos River.

Reference: "Report 48, Dams and Reservoirs in Texas, Historical and Descriptive Information," Texas Water Development Board, 1967.

TABLE 2.4-3
POSSIBLE FUTURE RESERVOIRS ON BRAZOS RIVER BETWEEN POSSUM KINGDOM RESERVOIR AND LAKE WHITNEY

Name	Location	Water Elevation When Filled (feet)	Storage Volume (acre-feet)
Turkey Creek	Downstream from Possum Kingdom Reservoir	884	159,000
Inspiration Point	Between Turkey Creek and Hightower	820	203,000
Hightower	Upstream of Lake Granbury	752	520,000
Bee Mountain	Between Lake Granbury and Lake Whitney	609	306,000

TABLE 2.4-4
SURFACE WATER CLAIMS FILED (IRRIGATIONAL) - SQUAW CREEK[a]

Applicant	Location of Applicant	Amount Requested (Ac-ft/yr)
Dean Williams	Within Squaw Creek Reservoir in Somervell County near Somervell-Hood County line	30
Carlisle Cravens	Within Squaw Creek Reservoir in Hood County near Somervell-Hood County Line	150

a) This list was derived from the “Water Rights Master File” of the Texas Water Rights Commission. There are no permits for non-irrigational water users on Squaw Creek.

TABLE 2.4-7
ANNUAL FLOODS AT BRAZOS RIVER GAGING STATION 8-0910
(NEAR GLEN ROSE)

(Sheet 1 of 3)

Location. 4.4 miles upstream from Paluxy River confluence. 6 miles northeast of Glen Rose at Brazos River Mile 511.

Catchment area. 24,830 sq. mi., approximately; of which about 15,590 sq. Mi. contributes directly to surface runoff.

Gage. Nonrecording at site 2.5 miles downstream prior to May 8, 1931; recording thereafter. At site 2.4 miles downstream May 9, 1931, to Sept. 30, 1957. Present gage used as supplementary flood gage for 1957. Datum of gage is 567.82 ft. above mean sea level, datum of 1929.

Stage-discharge relation. Defined by current-meter measurements.

Bankfull Stage. 20 ft.

Remarks. Stages affected by backwater from Paluxy River at times and, since 1945, by medium-water bridge 2.5 miles downstream. Peaks partly retarded by Possum Kingdom Reservoir since March, 1941.

Average Discharge. 1,555 cfs

Water Year	Date	Gage Height (Feet)	Discharge (cfs)
1924	Oct. 17, 1923	13.0	37,500
1925	May 8, 1925	15.1	45,700

TABLE 2.4-10
ANNUAL FLOODS AT GAGING STATION 8-0915 ON PALUXY RIVER NEAR GLEN ROSE

(Sheet 1 of 2)

Location. -- On left bank of Paluxy River at downstream side of pier of bridge on U.S. Highway 67, 1 mile upstream from Cross Branch, 1.2 miles southwest of Glen Rose, Somervell County, and 4.7 miles upstream from the mouth.

Catchment area. -- 410 sq. mi.

Gage. -- Nonrecording at site 1.8 miles downstream at datum 13.62 ft. lower prior to May 14, 1947; recording thereafter. Datum of gage is 609.66 ft. above mean sea level, datum of 1929, Fort Worth supplementary adjustment of 1942.

Stage-discharge relation. -- Defined by current-meter measurements below 150 cfs 1923-25; defined by current-meter measurements below 32,000 cfs and extended to 59,000 cfs by logarithmic plotting subsequent to May, 1947.

Historical Data. -- Flood of April 17, 1908, was the greatest since at least 1877, from information by local resident.

Average Discharge. -- 70.8 cfs

Water Year	Date	Gage Height (Feet)	Discharge (cfs)

TABLE 2.4-12
COMPARISON OF PROBABLE MAXIMUM PRECIPITATION MAXIMUM RECORDED RAINFALL AND MAXIMUM RAINFALL LIKELY TO OCCUR AT SELECTED GAGING STATIONS NEAR CPNPP

Station	Period of Record Analyzed	PMP[a] (Inches)	Maximum Recorded in 24 Hours (Inches)	Maximum Likely to Occur in 24 Hours[b] (Inches)
Iredell	1964-1971	39.5	4.45	22.4
Kopperl	1952-1971	39.5	4.90	20.2
Rainbow	1936-1971	39.5	6.00	23.6
Stephenville	1952-1971	39.5	7.75	29.6

a) 24-hour point PMP as obtained from HMR #33 (Reference 9) is approximately 39.5 inches for all gaging stations. 24-hour point rainfall was converted to 48-hour 64-square mile rainfall (38.7 inches) for PMF determination.

b) 24-hour maximum rainfall likely to occur as computed through use of a statistical envelope technique developed by Hershfield (Reference 11).

TABLE 2.4-13
UNIT HYDROGRAPH CHARACTERISTICS

		Lower SCR Catchment	Upper SCR Catchment (Except Maximum Six Hours)	Upper SCR Catchment (During Maximum Six Hours)
1.	A (Sq. Mi.)	20.3	38.0	38.0

TABLE 2.4-16
UNIT HYDROGRAPH CHARACTERISTICS FOR THE PANTHER BRANCH WATERSHED ABOVE THE SAFE SHUTDOWN IMPOUNDMENT

1. A = 3.47 Square Miles
2. L = 4.15 Miles
3. L_{ca} = 2.05 Miles
4. $(LL_{ca})^{.3}$ = 1.90
5. C_t = .6
6. $t_p = C_t(LL_{ca})^{.3}$ = 1.14 Hours
7. $t_r = t_p/5.5$ = .21 Hour
8. t_R = .5 Hour
9. $t_{pR} = t_p + .25(t_R - t_r)$ = 1.21 Hours
10. $t_{pR} = .5t_R$ = 1.46 Hours
11. C_p640 = 420
12. $Q_{pR} = C_p640 \times A / t_{pR}$ = 1,200 cfs
13. $q_{pR} = C_p640/t_{pR}$ = 347 cfs per Square Mile
14. W-50 = 1.4 Hours
15. W-75 = .8 Hour

2.5 GEOLOGY AND SEISMOLOGY

2.5.1 BASIC GEOLOGICAL AND SEISMIC INFORMATION

The site of the Comanche Peak Nuclear Power Plant (CPNPP) is located on the Comanche plateau, a subdivision of the Central Texas section of the Great Plains physiographic province (F2.5.1-1). Gently dipping Lower Cretaceous limestone and sandstone directly underlie the site.

Structurally, the site is located on the southern flank of the Fort Worth Basin (F2.5.1-3), a sedimentary depositional trough formed in mid-Pennsylvanian time. The trough is filled with Pennsylvanian and Permian sediments. A regional unconformity separates these Paleozoic sediments from the Lower Cretaceous sediments underlying the site (F2.5.1-5).

Two major fault systems, the Balcones and the Luling-Mexia-Talco fault zones, occur within 200 miles of the site (F2.5.1-3 and F2.5.1-4). Both of these fault systems can be observed on the surface. Subsurface faults have been identified within seven miles of the site. These faults appear to die out in sediments over 270 million years old. (See Section 2.5.1.2.4.)

Seventeen seismic events have been reported with epicenters within 200 miles of the site (F2.5.2-2). The closest large event was in Intensity VII and occurred in 1882 near Paris, Texas, 155 miles northeast of the CPNPP (F2.5.2-3). The nearest event was the Wortham-Mexia Intensity V-VI shock of 1932, occurring 90 miles southeast of the site (F2.5.2-6). The region within 200 miles of the CPNPP site has been divided, based on geologic structure, into tectonic provinces and subprovinces (F2.5.2-8). There have been no reported epicenters within the subprovince in which the site is located. An evaluation of the seismic history of the surrounding provinces as been made and a conservative maximum acceleration of 0.12 g has been selected for the Safe Shutdown Earthquake (SSE) (see Section 2.5.2.6).

Detailed investigation within five miles of the site has disclosed no evidence of surface faulting, hence eliminating the need for taking this factor into account for design purposes. The absence of surface faulting was confirmed in the detailed mapping of the excavations (see Section 2.5.4.5).

With regard to the stability of subsurface materials, there is no evidence in the site region indicating actual or potential uplift or subsidence, cavernous or karst terrain, tectonic warping or deformational zones pertinent to the site. Zones of alteration, weathering, structural weakness, unrelieved residual stresses or geologically hazardous materials are not in evidence.

Evaluations undertaken indicate that natural and man-made slopes at the Station site and on the reservoir rim will be stable.

The site investigation program consisted of the following:

1. Geological investigation and mapping of the site and surrounding area;

2. Test borings, in situ packer and infiltration tests and water level monitoring;

3. Geophysical surveys; and

4. Detailed geological mapping of all Category I excavations.

Studies pertinent to Section 2.5 have been performed by Dames & Moore, Consultants in the Environmental and Applied Earth Sciences, and Mason-Johnston & Associates, Inc., Consulting Geologists and Engineers. Information regarding these firms is provided in Section 1.4.

Studies and analyses pertinent to petroleum geology in Section 2.5.1.2.6 were supplemented by H. J. Gruy and Associates, Inc. of Dallas, Texas.

Plot Plans presented on Figures 2.5.5-5 and 2.5.5-6 illustrate the layout of facilities and the locations of borings. The location of the geophysical surveys is presented on Figure 2.5.4-14. Cross sections illustrating general features of subsurface conditions and foundation grades of Category I Station facilities are presented on Figures 2.5.4-40, 2.5.4-41, 2.5.6-10 and 2.5.6-11. The section locations are shown on Figure 2.5.5-5.

In 1989, and prior to CPNPP Unit 1 licensing, ongoing research funded by the NRC identified a possible capable fault in Southwestern Oklahoma. Field reconnisance by NRC contract seismologists identified the Criner fault in Southwest Oklahoma as possibly capable. Investigation of the Criner fault by the NRC seismologists and TU Electric seismologists allowed the NRC to conclude that the Criner fault did not pose a safety concern to CPNPP. In 1994, a review of the seismicity of the North Texas and Southwestern Oklahoma was performed. The review concluded that:

> CPNPP is located near the center of one of the world's major seismologically and geologically stable continental interiors. During the 300 year historical period no large earthquake has been recorded within 200 miles of the site. During this same period, no large earthquake which cannot be attributed directly to geologic structures known earlier through ongoing seismicity has been documented within this stable continental interior.
>
> The site is underlain by undeformed rocks of Cretaceous age more than 80 million years old. No geological faults have been found in these rocks near the site. Their sub-horizontal stratigraphy across hundreds of miles of exposure and as found in countless oil, gas, water, and investigation wells in Texas, Louisiana, Oklahoma and the adjacent states testifies to the tectonic quiescence of the region for many millions of years. In this region, excepting deformation associated with the Meers fault in Oklahoma, no evidence has been found of tectonic activity at the earth's surface younger than late Miocene age, or about 11 millions years ago.
>
> Prior to the completion of the PSAR for CPNPP in the early 1970's, only 78 earthquakes in the region had been large enough to be reported as felt events during the period of colonization. Since that time in the early 70's, because of increased sophistication of instrumental monitoring, an additional 225 mainly very small events have been recorded. All are spatially associated with earthquakes reported prior to that time. Therefore, even with the large increase in the number of recorded events afforded by sophisticated instrumental monitoring, there is no suggestion of a need to identify new earthquake sources. None of these newly recorded events are closer than 50 miles from the site. No earthquakes have been felt at the site since the beginning of site selection activities in the 1960s'.
>
> A total of 84 publications on the geology and seismology of the region, published since 1972, have been found in an intensive literature survey in support of this FSAR review. These publications have been studied carefully, and none suggest a need to consider any

more conservative evaluation of earthquake parameters than postulated in the original FSAR. In fact, there is much to suggest these original values for base ground acceleration of 0.12g horizontal and 0.08g vertical may have been overly conservative and that designs based on the minimum of 0.10g required by 10CFR 100, Appendix A, Paragraph V(2)(1)A, would be sufficiently conservative.

It is concluded that the site is acceptable from a geological and seismic standpoint for the facility designed for the Safe Shutdown Earthquake.

2.5.1.1 Regional Geology

2.5.1.1.1 Physiography and Geologic Setting

The site of the Comanche Peak Nuclear Power Plant (CPNPP) is located on the Comanche plateau, a subdivision of the Great Plains physiographic province [1]. The relationship of the site to these features and to other physiographic units in the region is shown on Figure 2.5.1-1. The Great Plains province is bordered on the east by the Coastal Plain, Ouachita and Ozark Provinces. The western and northern boundary of the Coastal Plain province coincides in general with the limit of the Upper/Lower Cretaceous sedimentary boundary. The boundary extent in common with the Great Plains (Comanche Plateau area) is reasonably sharp and marked by the contrast between the harder limestones (Lower Cretaceous) and the softer shale-chalk-sandstone (Upper Cretaceous) to the east. North of the Brazos river, the Central Lowlands-Coastal Plain boundary is less distinct and the Coastal Plain limit is arbitrarily continued at the same geologic position by placement at the base of Upper Cretaceous.

The closest point of the Coastal Plain Province is 25 miles east of the site. The Coastal Plain is comprised of semiconsolidated and unconsolidated sediments of upper Cretaceous, Teriary, and Quaternary age. The geological materials become progressively younger and are generally softer towards the Gulf of Mexico; all the sediments dip gently seaward.

Near the CPNPP, the Great Plains province of Texas is subdivided on the degree of erosion of the resistant Lower Cretaceous limestone cover and on the nature of the older rocks thereby exposed. The Comanche plateau subdivision in which the Station site is located is a submaturely dissected area which slopes eastward at a gradient conforming the dip of the lower Cretaceous rocks. The eastern boundary of the Comanche plateau, from a point near Waco southward, is formed by the Balcones escarpment.

The Palo Pinto Country adjoins the Comanche Plateau to the Northwest. Palo Pinto country, named by Hill [1], is the locality in which Pennsylvanian rocks have been exposed by stripping away of the Edwards limestone (Upper Cretaceous). It is characterized by steep sided mesas cut by canyons, the mesas being remnants of strong sandstone beds. Between the mesas, on lower-lying shales, are rolling, mesquite-covered plains.

The formations forming the Comanche Peak Plateau and the outlier remnants of the Callahan Divide to the west are principally limestones of Lower Cretaceous age. These more resistant rocks are grouped with associated sands and calcareous clay or marl units into three subdivisions, the Trinity, Fredericksburg, and Washita groups (Figure 2.5.1-2). South and west of the Brazos River, the youngest (Washita) rocks are thin and have a small extent of a real outcrop. This group is absent in the site vicinity. The Fredericksburg group of formations (Edwards and Comanche Peak Limestones and underlying Walnut Clay) are confined to the major drainage

divides; the only complete section in the site vicinity is at Comanche Peak, the prominent landmark a little more than five miles north of the plant site. The Trinity rocks are roughly equal in a real extent to those of the Fredericksburg. They crop out in the western marginal area of the plateau and in the valley areas projecting southeastward. Classic exposures are present in the valleys of the Brazos River, Paluxy river, and Squaw Creek in the site area. The plant dams and reservoirs are all within the Glen Rose bedrock outcrop with the overlying Paluxy Sand on the adjacent divides. The underlying basal Trinity sands (Twin Mountains Formation), unexposed in the Squaw Creek drainage, crop out about eight miles to the southwest of the site in the Paluxy River Valley.

The Trinity formations exhibit characteristic terrain aspects. The outcrop area of the Paluxy Sand is confined to the summit regions of the drainage divides and forms gently rolling hills of red, sandy soil which supports deciduous trees and native grasses. Areas underlain by the Glen Rose Formation are typically prairies having relatively steep, stairstepped slopes developed on limestone alternating principally with claystone, siltone and/or shale. The residual soil derived from the Glen Rose beds supports cedar and sparse grassland vegetation.

A flat, broadly undulating plain lying to the west of the site characterizes the outcrop area of the Twin Mountains formation, and its vegetation cover closely resembles that described for the Paluxy Sand.

Topographic elevations in the site region range from about 550 feet to 1000 feet above sea level.

2.5.1.1.2 Geologic History

Figure 2.5.1-3 shows the regional tectonic structures within a two hundred mile radius of the CPNPP site. The major features shown on this figure are discussed in this section. Each of the major structural features has undergone a distinct geologic history. By far, the greatest tectonic activity on a regional scale occurred prior to Mesozoic time.

Seven tectonic provinces have been delineated within a two hundred mile radius of the CPNPP site. These provincial boundaries are shown on Figure 2.5.2-2 and their use in developing the Safe Shutdown Earthquake is discussed in Section 2.5.2.6.

1. Central Texas

   The Llano Uplift (Figure 2.5.1-3) is post-Early Ordovician and pre Late Pennsylvanian in age. In late Pennsylvanian time, the Precambrian surface was 10,000 feet higher in the western part of the Llano uplift than beneath the flanking Fort Worth Basin. Erosional losses indicate that uplift accounted for one-third and basinal subsidence for two-thirds of the vertical movement in these structural adjustments [2].

   The northeast trending horsts (Figure 2.5.1-4) of the region developed at the close of the mid-Pennsylvanian contemporaneously with the Ouachita Orogeny which intensely folded the equivalent and older beds in Oklahoma and Arkansas.

   The Llano Uplift remained stable during Mesozoic and Cenozoic time. Continental elevation during the Cenozoic resulted in the removal of the relatively thin cover of Mesozoic rocks, exhuming rocks ranging from Precambrian to Pennsylvanian in age

which had been overlapped by Lower Cretaceous limestone and shale in the Llano region.

2. North of the Llano Uplift

North of the Llano Uplift are a series of arches (Bend, Lampasas, Red River, Muenster) and basins (Fort Worth or Strawn). Most of the tectonic activity on these structures took place in mid-Pennsylvanian time and just preceded the Ouachita Orogeny (see below). The Strawn (Fort Worth) Basin was initiated at the same time as neighboring uplifts and represents differential warping of the basement. The Strawn Basin continued to receive sediments through upper middle-Pennsylvanian time and was progressively deepened.

The Red River Uplift and Muenster Arch (Figure 2.5.1-3) likewise were initiated either during or at the close of the Mississippian. Their history in Mississippian time appears to coincide with that of the Llano region (as a positive element but not pronounced uplift). Both Llano and Red River uplifts and Muenster Arch were submerged by the lower Pennsylvanian sea.

3. Ouachita Folded Belt

In the middle Cambrian a trough developed in the area which became the site of continuing sedimentation from late Cambrian through early Pennsylvanian time [3]. Compressional forces from the south during later Pennsylvanian time (Ouachita Orogeny) metamorphosed these sediments and elevated them into a chain of mountains. Major crustal movements terminated near the end of the Paleozoic era. Erosional denudation of the mountain belt occurred simultaneously with its development and continued through early Mesozoic time. The eroded surface and the younger, unaltered Paleozoic strata served as the foundation for the Jurassic and younger sediments of the Gulf Coastal Plain.

4. Southern Oklahoma Uplifts

Orogeny in the Wichita mountains (Figure 2.5.1-3) began no later than in early Pennsylvanian time. Numerous pulses of folding doubtless affected the Wichita throughout middle and late Pennsylvanian time and continued into the Permian. The last strong pulse was in the early Permian [4].

The Arbuckle mountain region experienced volcanic activity in Cambrian time and sedimentation throughout Paleozoic time, culminating in a late Paleozoic orogeny [5]. During the orogeny, there was close folding of the Arbuckle anticline and Ardmore basin, overturing and thrusting of some 30,000 feet of geosynclinal sediments, and collapse of the eastern segment of the Southern Oklahoma geosyncline. Two orogenic pulses occurred. Slight additional folding persisted into early Permian time.

Major deformation of the Ouachita mountains occurred in early Pennsylvanian time, after more than 35,000 feet of Paleozoic sediments had accumulated in the gradually downwarping basin.

5. Gulf Coast Plain

Subsidence of the Coastal Plain contemporaneous with tilting along its coastline during each Tertiary epoch of deposition resulted in a thickening of these strata to form prisms of sediment. Elevation of the upland area and sinking of the Gulf floor resulted in southeastward development of offlapping, successively younger continental shelves [6].

The Sabine Uplift (Figure 2.5.1-3) on the Coastal Plain has experienced periods of growth, dormancy and rejuvenation.

In Mesozoic time, the East Texas embayment, a synclinal depression, developed over a large portion of the Coastal Plain of northeast Texas. Salt deposits underlie most of this basin [7]. Numerous salt domes have been found in this area and comprise the inner salt dome province of the Texas Coastal Plain. The embayment persisted until near the close of the Eocene. Its original northwest axis was then modified by the Sabine uplift so that the south portion of the embayment now trends north while the northern part is deflected to the northeast [8].

Several prominent fault zones exist in the Coastal Plain. Because of their particular relevance to the site, their history of movement is discussed in Section 2.5.2.3.

2.5.1.1.3 Stratigraphy

A geologic map of the region is presented on Figure 2.5.1-4. Figure 2.5.1-2 summarizes the stratigraphy for the region around the site. The cross-sections provided in Figures 2.5.1-5 and 2.5.1-6 illustrate the stratigraphic relationships in the region along east-west and north-south lines, respectively. Sedimentary rocks of the Lower Cretaceous Comanche series (maximum age 136 million years) crop out in the Station site vicinity. Because of the easterly dip of these strata, progressively younger beds extending through the Upper Cretaceous Gulf series sediments (age 65-100 million year) outcrop to the east.

The Comanche series thins westward from the Station site [9] and is underlain by westerly dipping pre-Cretaceous sediments of Permian and earlier age (225 million years and older). Exposures of these older rocks become more abundant in a westerly direction where the Comanche series has been removed by erosion.

The Gulf series consists of the Navarro, Taylor, Austin, Eagle Ford and Woodbine formations. Total Thickness of the series ranges up to about 2,800 feet. The sequence consists of marl, limestone, limey shale, chalk, shale, sand sandstone and clay, along with minor lignite and gypsum.

A regional unconformity separates the Comanche series from the overlying Gulf series. However, here are numerous facies changes along both strike and dip caused by changing depositional environments [9] [10]. The Washita group, at the top of the Comanche series, consists of the Buda Formation (limestone), the Del Rio Formation (shale) and the Georgetown Formation (limestone). The Washita group ranges up to approximately 300 feet in thickness.

The Fredericksburg group, occurring stratigraphically below the Washita, has a maximum thickness of about 600 feet in the region and consists of the Kiamichi Formation (limestone), the

Edwards Formation (limestone), the Comanche Peak Formation (limestone), and the Walnut Formation (shale).

Below the Fredericksburg group lies the Trinity group, which forms the base of the Cretaceous sequence. Three formations of the Trinity group comprise bedrock in the site region and are approximately equal in thickness. In descending order, they are the Paluxy, the Glen Rose and the Twin Mountains formations. The Paluxy Formation at the top of the group is a sand which thins southward and eastward (downdip). The Paluxy Formation has been eroded from the immediate Station and reservoir area. However, it does crop out on the periphery of the site area and there consists of fine-to very fine-grained, well-sorted, poorly-cemented friable sandstone with occasional siltstone and claystone interbeds. The Paluxy Formation is mined locally for industrial uses including glass making, foundry molds and mineral filler.

The Glen Rose Formation, which underlies the Paluxy, constitutes the principal bedrock formation in the Station site area. It pinches out to the west (updip) and to the north and is absent in northern Wise County [9]. Eastward the Glen Rose Formation thickens substantially in the subsurface and contains a massive evaporite bed. Alternating beds of resistant limestone and weak claystone form stair-step topography where the Glen Rose is exposed. The Paluxy-Glen Rose contact in this area is abrupt, distinct and conformable [10].

Below the Glen Rose unit lies the Twin Mountains Formation. This stratum forms a gradational contact with the Glen Rose formation and is composed principally of sandstone, limestone, and claystone [2]. The sandstones are water bearing and serve as a source for water supplies in the site vicinity [11]. The Twin Mountains Formation is not exposed in the immediate site area.

In the subsurface to the east, rocks of Jurassic age are present. There strata range in age from 136 to 195 million years and include the Cotton Valley, Buckner, Smackover and Louann formations. The Jurassic sequence may be underlain by the Eagle Mills Formation of Triassic age (at least 195 million year old) and/or lower Paleozoic sedimentary and metamorphic rocks.

Generally speaking, the rocks in the above section became more dense with increasing age or depth in the stratigraphic column [12] as indicated on Figure 2.5.1-7.

West of the Station site and beneath the veneer of Lower Cretaceous formations (Figure 2.5.1-5) lies a succession of Permian, Pennsylvanian, Mississippian and Cambro-Ordovician strata consisting predominantly of resistant limestone and shale with some sandstone. Basement granite likely underlies this Paleozoic section.

North of the Station site, in southern Oklahoma, the Cretaceous section is similarly composed of the Gulf and Comanchean series (Figure 2.5.1-6). However, the Gulf series here is thinner. In Oklahoma, the Comanchean is comprised of the same three groups as in Texas: the Washita, Fredericksburg and Trinity groups. The Washita is thicker and contains more sand in this region. The Paleozoic section in southern Oklahoma consists mainly of limestone, dolomite, marl and shale dating from the Cambrian through the Permian. One sandstone unit appears in the lower Cambrian. The Precambrian basement (over 570 million years in age) consists mainly of quartzite, granite, and gabbro.

2.5.1.1.4 Structure

1. General

A large number of varied regional geologic structures are present within 200 miles of the site. These are described in the following paragraphs, subsection 2.5.2.3 and shown on Figures 2.5.1-3, -4, -4a, -5 and -6. Tables 2.5.1-1 through 2.5.1-4 list the principal fold and fault structures in Texas and in the adjoining states of Oklahoma, Arkansas and Louisiana.

a. North Central Texas (Great Plains Physiographic Province)

The Llano Uplift, located approximately 100 miles southwest of the site, is structurally a large dome. Precambrian rocks dating more than 570 million years in age are exposed in the center of the dome over an area roughly 40 to 70 miles and are surrounded by formations of Paleozoic age (225 to 570 million years old) and Cretaceous rocks deposited 65 to 136 million years ago. The Precambian of the uplift consists of metamorphic rocks (schist, gneiss and marble), batholithic intrusions (granite) and late dike intrusions (felsite). Extensive faulting is associated with the Llano Uplift (Figures 2.5.1-3, -4, -4a and -6) and extends to the northeast and southwest under a covering of late Pennsylvanian and Cretaceous sediments. Evidence for extension of this faulting into the site vicinity could not be found in the field through stereoscopic study of areal photographs, however, data from recent hydrocarbon exploration in the site vicinity has indicated this faulting is present in the subsurface to the west of the site. (See Section 2.5.1.2.4.) Several major structural arches also originate in the Llano Uplift, and they, too, extend under the Cretaceous and Upper Pennsylvania formations [8]. One of these features, the San Marcos arch, plunges southeastward into the Coastal Plain and coincides in position and trend with known Precambrian folding. Other structures, namely the Lampasas Arch trending northeast, the Edwards Arch trending southwest and the Bend Arch trending north, possess an axial orientation approximately at right angles to the lines of Precambrian folding.

North of the Llano Uplift, differential warping and uplift associated with faulting and subsidence in Pennsylvanian time formed the Fort Worth Basin and associated structurally high areas. The structural highs include: the Bend Arch to the west, the Red River Uplift and its continuation, the Muenster Arch to the north, and the Lampasas Arch to the south.

The Forth Worth Basin or Syncline has a northwest-southeast axis and extends as far to the northwest as southern Clay County. Because most of the strata in the basin were deposited during the Strawn time of the Pennsylvanian Period, the basin is commonly referred to as the “Strawn Basin.” The full thickness of Pennsylvanian sediments in the Forth Worth Syncline is not known. No faults are known or suggested in the Basin. The Pennsylvanian section is comparatively thinner over the Bend Arch, Red River Uplift, and Muenster Arch structural highs.

The Bend Arch is a northward plunging anticline and is the most pronounced of the arches originating from the Llano Uplift. Because it originates from the north

side of the uplift, there is a possibility that its southern extension may be connected with the southwest trending Edwards Arch. The Bend Arch has probably resulted from two earth movements: a homoclinal tilt to the southwest in upper Pennsylvanian time, and a Post-Permian tilt of the entire region to the northwest, resulting in the northwest dip of the Pennsylvanian and Permian sediments.

The Muenster Arch, together with the Wichita Mountains Uplift comprise an uplift some 350 miles long. The trend has a Precambrian core and is flanked with truncated lower and middle Paleozoic strata. Geophysical evidence indicates a structural relationship between the Muenster Arch and the Wichita Mountain Uplift (Figure 2.5.1-8). The arch is completely blanketed by Cretaceous sediments and is shown in Figure 2.5.1-6.

The Lampasas Arch is a broad arch originating in the northeast portion of the Llano Uplift and is shown on Figure 2.5.1-6.

The Hardeman Basin is a depression at the western end of the Red River Uplift, filled with Pennsylvanian and Permian sediments.

b. Southern Oklahoma (Wichita-Arbuckle-Ouachita Mts.)

North of the Red River Uplift, in Oklahoma, are several major uplifts. From west to east, they are the Wichita Mountains, the Arbuckle Mountains and the Ouachita Mountains (shown on Figure 2.5.1-3 as the Ouachita Mountains uplift).

The topographic relief of the Wichitas averages generally less than 500 feet but ranges up to approximately 1,400 feet at Mount Scott (Altitude 2,840 feet) [4]. The Wichitas form hills, low mountains and ridges that emerge from a nearly flat plain. Forming the core and the principal part of the mountains are northwestward-trending igneous rocks (granite, anorthosite, rhyolite porphyry and gabbro) of Cambrian age. On the plunging east end of the uplift, Paleozoic rocks are now exposed in the form of ridges and isolated hills. These ridges are approximately as they existed when they were covered by early Permian sediments (shale and conglomerate) that form the extensive plains surrounding the Wichita Mountains.

The Arbuckle Mountains, 100 miles east of the Wichitas, are mostly gently rolling plains, with their major relief (607 feet) in the western portion. They are formed by a large inlier of folded and faulted Paleozoic and Precambrian rocks. It is covered on the east, north and west by gently westward-dipping Pennsylvanian and Permian strata and on the south by gently southwest-dipping early Cretaceous sediments of the Gulf Coastal Plain [5].

Immediately to the east of the Arbuckles are the Ouachita Mountains which are principally a flysch sequence quite unlike the Arbuckles in stratigraphy and structural development. There are three areas where pre-Mississippian sedimentary rocks are exposed. The Broken Bow-Benton anticlinorium is the one major structural component of the Ouachita Mountains that can be projected with

confidence into the subsurface in North Texas (Lamar and Red River counties, approximately 150 and 175 miles east-northeast of the site).

Each of the above uplifts is accompanied by extensive faulting, as shown on Figure 2.5.1-3. The major faults in Southern Oklahoma are listed in Table 2.5.1-3; those of the Arbuckles are mainly normal faults and those of the Ouachitas are mainly thrust faults. These faults all pass beneath the Cretaceous overlap of sediments without apparent evidence of offset.

c. Eastern Texas (Gulf Coastal Plain)

The principal features of the Gulf Coastal Plain are included in Figure 2.5.1-3. The Ouachita folded belt (synonymous with the Ouachita structural front and the Ouachita tectonic belt) is the buried southernly extension of the Ouachita Mountain uplift [14]. The fold belt has a minimum length of 1,300 miles and a width of 90 miles and lies under the inner margin of the Coastal Plain, ranking with the Appalachian belt in order of magnitude and in significance as a major continental structural feature [3]. Their subsurface southwestward extension from the Ouachita Mountains south passes along the east side of the Fort Worth basin, curving around the Llano uplift and trending westward as far as the Marathon uplift and thence southward, probably into Mexico. Deformation, including thrusting, is considerable in the belt. Sediments of the Ouachita facies are metamorphosed to varying degrees.

The structure of the Gulf Coastal Plain itself assumes a broad homocline dipping gently gulfward. Regional structural features that alter the general structure and stratigraphy of the plain are the Sabine Uplift, the East Texas Embayment, the San Marcos Arch and the Rio Grande Embayment.

A complex system of normal faults follows the margin of the Coastal Plain coastward of the Ouachita structural front. Three individual systems of the faults are recognized: the Balcones, the Luling-Mexia-Talco and the Charlotte-Fashing fault zones. The surface trace of the Balcones fault probably overlies the Ouachita folded belt along its considerable length [8]. The zone probably extends as far north as Kaufman County (90 miles east-northeast of the site) and as far south as Uvalde County (240 miles southwest of site). Displacement along the fault decreases markedly both north and south of Bexar County (200 miles south-southwest of the site).

The Luling-Mexia-Talco fault zone lies coastward of the Balcones zone and is comprised of individual faults largely antithetic to the southeastward throws of the Balcones.

Within the Luling-Mexia-Talco fault system, grabens of varying widths are common. An en echelon pattern to the individual faults within the system is normal [15].

The Charlotte-Fashing fault system is coastward of the Luling Fault system and may be considered an echelon to it. Major grabens comprise part of the system.

The location of the fault system is approximately 200 miles from the site and is shown on Figure 2.5.1-3.

The Sabine Uplift is a large, relatively flat-topped dome with gently sloping flanks in eastern Texas and northwestern Louisiana. It is reflected in the surficial Tertiary strata. Faulting in the Mt. Enterprise and Rodessa fault systems, Figure 2.5.2-2, has somewhat modified the structure.

Flanking the west side of the Sabine Uplift is the East Texas Embayment. The Embayment is situated in the bend of the Ouachita fold belt as its trend changes from west to south in northeast Texas and southeast Oklahoma. Numerous piercement salt domes and some faults appreciably modify the general simplicity of the basin [16].

The final Coastal Plain structure to be considered is the San Marcos Arch. It is a broad, gentle, structural nose extending southeast from the Llano Uplift. It separates the East Texas and Rio Grande embayments and plunges southeast along its trend.

2. Geophysical Surveys

Two types of geophysical investigation have been utilized to examine regional geologic structure and assist the identification of tectonic provinces. These methods include gravity and natural gamma aeroradioactivity surveys.

a. Gravity Survey

The regional Bouguer gravity map (Figure 2.5.1-8) depicts large gravity anomlies, providing an indication of the rock densities associated with the known regional tectonic features and some insight into less well known basement features. The Bouguer reduction commonly yields negative values for areas which are located in continental interiors. Positive Bouguer anomaly values (observed Bouguer gravity minum regional Bouguer gravity) generally indicate emplacement of high-density rocks near the surface [68] such as Llano Uplift.

Major lithologic-structural divisions of the basement agree well with the regional Bouguer gravity trends and regional gravity configuration is controlled largely by basement phenomena. In Texas, the general westward decrease in Bouguer values is caused by the isostatic effect of the High Plains.

The site, as shown on the regional Bouguer gravity map is located within the Fort Worth (Strawn) Basin and west of the Ouachita tectonic belt [19]. The features are shown on Figure 2.5.2-2. Basic data for construction of the map came from field measurement of the total gravitational force (commonly called absolute gravity), using the pendulum, and from conventional gravity-meter surveys which have been correlated with the absolute gravity determinations.

The updip limit of the Ouachita facies coincides with a series of gravitational maxima trending in the same general direction and also with both the

Luling-Mexia-Talco fault system and the Choctaw fault system farther north (Figure 2.5.1-8, 19).

Conspicuous positive Bouguer gravity anomalies are apparent from a series of maxima which coincide with the Muenster and Wichita uplifts and the Amarillo Uplift (Figure 2.5.2-2). These maxima begin rather abruptly in northwest Collin County, Texas, (immediately north of Dallas) and extend northwest through Oklahoma. The maximum of +35 milligals on the Wichita trend in Kiowa and Greer counties of Oklahoma (approximately 200 miles north-northwest of the site) is contrasted to a -81 milligal minimum to the south in Wilbarger County, Texas (approximately 150 miles northwest of the site). The amount of basement uplift and the density contrast between granite and flanking sedimentary rocks is inadequate to account for the magnitude of the anomaly. Either there is a greater amount of gabbroic rock in the Precambrian of the Wichita-Amarillo trend than is apparent from examination of surface exposures and drilling records, or the answer lies in the distribution of mafic material in the subcrust.

A crustal model for Central Texas [65, 66] is shown on Figure 2.5.1-8. Calculated and observed Bouguer gravity anomalies show good correlation and agreement is also found with crustal seismic models proposed by others for Texas. Crustal thickness in the site vicinity is between 40 and 50 km. (25 and 31 miles) according to the model.

All of the major structural uplifts of the southern Mid-Continent correspond to regional isostatic maxima and the basins with gravity minima [67]. The overall isostatic anomaly pattern (see Figure 2.5.1-8, inset) is broadly coincidental with basement structure; however, some broad-wavelength anomalies, one of which is also of high amplitude, apparently result from density variations deep within the crust rather than from structural relief. The most prominent of these anomalies is a 200-mile-long minimum which is aligned east-west across Central Texas from near the New Mexico border to near the Ouachita tectonic belt [67].

The structural grain of the Marathon-Ouachita orogenic belt (stable Ouachita, see Figure 2.5.2-2) is represented by a series of disconnected gravity minima and a parallel nearly continuous, lineal gravity maximum. This elongated gravity maximum can be traced for about 500 miles as a continuous feature from the Ouachita Mountains to near the Marathon area and corresponds closely with the axis of greatest metamorphism in the Ouachita trend.

A major 90 milligal Hayford-Bowie isostatic gravity minimum is centered in the Ouachita Mountains and includes the adjacent Arkoma basin.

Isostatic and Bouguer gravity anomalies produced by the Waco Uplift are superimposed on the broader rimming gravity maximum. This structure has been shown to be faulted and anticlinal, and it probably represents a crustal block partially involved in late Paleozoic orogenic thrusting related to the Ouachita belt [67].

The site is situated on the central stable continental land mass and exhibits a Bouguer gravity value averaging -48 miligals [19] with low lateral gradients.

These gravitational trends indicate that the site is far removed from tectonic boundaries and confirm the regional tectonic provinces developed in Section 2.5.2.2.

b. Radioactivity Survey

Airborne measurement of terrestrial radioactivity serves as an aid to geologic mapping and as general background data for later environmental monitoring. Varying amounts of uranium, thorium, and potassium in the surface rock and soil generate measurable gamma radiation [17]. A regional natural gamma aeroradioactivity map on Figure 2.5.1-9 shows the gamma ray intensity measured from an aircraft at 500 feet above the ground surface. Flight-line spacings were one mile and two miles. The Upper Cretaceous units possess individual gross lithologic homogeneity which permits association of aeroradioactivity patters with particular units [18]. The Lower Cretaceous outcrop area is characterized by lithologic variation and consequent radioactive mineral variations but most stratigraphic units are too limited in a real extent to permit their differentiation by the scintillation detector. The strata are so nearly horizontal that geologic contacts approximate the topographic contours. In this terrain, few correlations are possible.

2.5.1.1.5 Stability of Subsurface Materials

Information relating to the stability of subsurface materials in the site vicinity are provided in Section 2.5.1.2.6.

2.5.1.1.6 Groundwater

A detailed description of groundwater is provided in Section 2.4.13.

2.5.1.2 Site Geology

2.5.1.2.1 Physiography

The Station site is located in the Squaw Creek drainage area immediately west of the Brazos River as shown on Figure 2.4-6. The Station area will be prepared for construction by leveling a ridge between Squaw Creek and Panther Branch, one of its tributaries. Figure 2.4-1 depicts the locality. The site for the main dam, Squaw Creek Dam, is on Squaw Creek just below the mouth of Panther Branch. A smaller impoundment dam (Safe Shutdown Impoundment) will be built on Panther Branch about 3,000 feet upstream from Squaw Creek. Location of the principal Station components are presented on Figure 1.2-1 and detailed topography also is illustrated on Figure 2.4-1.

The site is situated on the indurated and consolidated Lower Cretaceous sediments typical of the Comanche Plateau subdivision of the Great Plains physiographic province. Maximum relief in the immediate site area is approximately 220 feet, with grades ranging as low as elevation 640 feet in creek floodplains to elevation 860 feet in uplands. The floodplains of Panther Branch and Squaw Creek vary in width to approximately 1,000 and 3,000 feet, respectively. Surface materials in the floodplains are principally fine-grained clayey soils.

Valley slopes rising above the floodplain are relatively gentle to moderately steep, ranging from 15 to 30 degrees or more, and generally exhibit a somewhat stair-stepped appearance. Rock outcrops of limestone and claystone comprise approximately 40 to 60 percent of the slopes. In other areas, including flat-topped plateau remnants, bedrock frequently crops out and/or is mantled by a thin cover of residual soil which generally consists of clay silt and/or sandy clay material.

Vegetation in the site area includes cedar, scrub oak, juniper, mesquite, cactus and various types of grass. Large deciduous trees grow in the valley bottoms.

2.5.1.2.2 Geologic History

The history of geologic events in the site area subsequent to the development of an erosional surface on the Precambrian basement is one of crustal downwarping, alternate marine invasion and retreat, and related accumulation and erosion of sediments.

Throughout Paleozoic time, marine submergence alternated within periods of land uplift and emergence. During these pulsations, sedimentation in the site region varied from deep-water marine limestones and shales to sandstones and shales carried into shallower seas from emergent sourcelands. Cycles of deposition alternated with periods of erosion and partial removal of these materials. Major interruptions in the depositional history can be identified by significant unconformities at the contact zones between the Cambro- Ordovician limestone and Mississipian shales and limestones, and between the Pennsylvanian shales/sandstones and the lower Cretaceous formations immediately underlying the site.

Extensive faulting is associated with the Llano uplift and extends to the northeast (toward site) and under a covering of late Pennsylvanian and Cretaceous sediments. This faulting is associated with uplift of Llano Uplift and Lampasas Arch (Figures 2.5.1-3, -4, -4a, and 6) and downwarping to the west (Figure 2.5.1-5). The major time of fault activity occurred in mid-Pennsylvanian time just prior to the Ouachita Orogeny.

Mesozoic history began with much of North-Central Texas emergent and this condition continued through the early Mesozoic (Triassic and Early Jurassic). Following regional tilting to the south and east, the ancestral Gulf of Mexico came into being and the great submergence of Cretaceous time succeeded the initial Late Jurassic marine invasion. The Balcones Fault Zone is generally considered as a basement hingeline with increased rate of submergence and depositional thickening to the south and east of this perpherial fault zone. The Jurassic seas of the East Texas embayment extended toward this hinge zone and then lapped out against the terrain of the Ouachita Tectonic Belt. The site area is about 75 miles west of the nearest inferred Jurassic shoreline.

The early Cretaceous seas overlapped the Jurassic strata and transgressed the peneplained, eastward sloping surface developed on the generally westward-dipping Paleozoic rocks of the site area (Figure 2.5.1-5). Cretaceous history is marked by a series of depositional cycles, i.e., progressive transgressions with stillstands and/or minor regressions. Except for marginal coastal areas dominated by sand deposition, these cycles are basically couplets of clastic deposits (sand or shale) followed by carborate deposits. In the site area, the basal Cretaceous sands (Trinity or Twin Mountains) and the Glen Rose Limestone, laterally replaced by the lower part of the Paluxy Sand, represent the initial major cycle. The upper part of the Paluxy Sand and the overlying Walnut Clay plus the Comanche Peak and Edwards Limestones constitute the middle Lower

Cretaceous cycle. The last Lower Cretaceous cycle (Washita) has been removed by erosion in the site vicinity. These three cycles are shown on Figure 2.5.1-2.

Deposition and erosion continued through the Upper Cretaceous and into the Tertiary with final continental uplift occurring in late Tertiary time accompanied by renewed erosion and removal of the Cenozoic sediments as well as portions of the underlying Cretaceous rocks. This erosional cycle persists into the present.

2.5.1.2.3 Stratigraphy

Within the general 5-mile radius area of the site vicinity, the stratigraphic units exposed consist of Quaternary fluvial deposits exposed in the drainage lowlands and Lower Cretaceous strata of the Edwards, Comanche Peak, Walnut, Paluxy, and Glen Rose formations exposed on the adjacent uplands. The Site vicinity Geologic Map, Figure 2.5.1-10, illustrates the outcrop area of each formation. The geologic column, figure 2.5.1-11, illustrates the formation sequence.

The Paleozoic section is not exposed within a five-mile radius of the site. A typical Paleozoic section as obtained from regional mapping and recent gas exploration wells in the site vicinity is also presented on Figure 2.5.1-11. This Paleozoic section consists of predominantly sandstone and shale of the Strawn and Atoka Stoke Series (Pennsylvanian); limestones of the Marble Falls Formation (Pennsylvanian) and Ellenburger Formation (Ordovician); and sandstone of the Hickory Formation (Cambrian).

These sediments overlie Precambrian granite basement. Because the Paleozoic sediments are not exposed in the site vicinity, these have not been included in the detailed stratigraphy given below.

Quarternary deposits in the site areas are recent floodplain alluvium (Qa1) and Pleistocene fluvial terrace sediments (Qt). These deposits consist of gravel, sand, silt, silty clay, and organic material and are confined to the bottoms of the Squaw Creek, Paluxy River, and Brazos River valleys. The scattered patches of Pleistocene fluvial terrace remnants are adjacent to the recent floodplain alluvium but at a slightly higher elevation.

The areal distribution of the modern floodplain alluvium and the terrace remnants of older floodplains conforms with that of the 1:250,000 scale, Dallas Sheet, Geologic Atlas of Texas (Univ. Texas Bur. Econ. Geol., 1973). Regional treatments of Brazos River terrace deposits [50, 51] document three terrace levels of Pleistocene age in the general area under consideration. The separate levels, as recognized in the Waco (McLennan County) area downstream are referred to by elevation above the base of the modern floodplain of the Brazos. The first terrace is about 30 feet above, the second terrace 45 to 60 feet above, and third terrace 90 to 120 feet above. Those terraces mapped in the site area represent the first and second and possibly the third. No scarps were noted that would assist in defining the separate terraces. Data on age in years B. P. (Before Present) are not available. Typical Pleistocene vertebrate fossils - mammouth, mastodon, camel, horse, etc., have been collected from all three terraces [50, 51, 52, 53, 54]. At higher elevations outside the area, from the tops of buttes in the Lampasas Cut Plain, lag gravels considered to represent the Uvalde terrace gravel (Micocene-Pliocene) have been reported [54].

The Edwards, Comanche Peak, and Walnut formations are of little relevance to the immediate site vicinity but are typically developed at nearby Comanche Peak to the north (Figure 2.5.1-10). Descriptive features of each unit are summarized below:

Edwards Limestone (Ked): massive, light gray, scarp-forming high purity limestone with reef-rock organisms (typically rudists), locally with abundant chert nodules in thinner-bedded, dense, lime mudstones; forms upper scarp slopes of high areas (Lampasas Cut Plains); thickness 16 - 60 feet in Waco Geologic Atlas Sheet, about 30 feet in site vicinity.

Comanche Peak Limestone (Kcp): nodular, gray to white, fairly hard but slope-and-bench forming, low purity limestone with numerous clay partings and filled burrows; distinct calcareous shale beds in he upper part and a few, harder, bench-forming oyster-bearing beds near the base; about 90-100 feet thick in site vicinity.

Walnut Clay (Kwa): dark grey to brown, fossiliferous, calcareous clay with hard massive beds of oysters in the lower part; thick, chalky, marly, nodular limestone interbedded with thin shale in upper part; about 70 feet thick in site area, thins to north and thickens southward by facies replacement of upper Paluxy Sand.

The Glen Rose/Paluxy contact as mapped (Fig. 2.5.1-10) marks the abrupt lithologic change from the gray-to-white ledge forming limestones of the Glen Rose to the overlying reddish, unconsolidated, sandy deposits of the Paluxy. Associated changes occur in soil type, vegetation, cultural use, and topographic nature. These distinctions are quite evident on the ground, are reflected clearly on areal photos, and the cartographic boundary was transferred without difficulty to 7.5 minute topographic quadrangles, scale 1:24,000, covering the area.

Standard field mapping procedures employed involved initial ground check points, by car mileage, on all country roads and on selected permissible private roads. The logged data, recorded on county road maps (scale 1 inch = 1 mile), controlled the boundary trace as extended on photo-index sheets or photomosaics. The basic reconnaissance data were refined by use of stereo areal photos for inaccessible or critical areas or for secondary marker beds.

In a similar manner, other formation boundaries within the 5-mile radius were mapped and extended a mile or more beyond. The detailed areally geology of the study area was compiled on a composite topographic base map of scale 1 inch = 3000 feet. Figure 2.5.1-10 is a reduced and simplified version of this base map.

The Paluxy Sand (Kpx) is a weathered, friable, well-sorted, fine- grained, poorly-cemented sandstone with some soft claystone and hard siltstone remains in the immediate site vicinity. The Paluxy Sand is a really extensive and cultivated on the drainage uplands.

The Glen Rose Limestone (Kgr) constitutes the bedrock of the Station site and reservoir area. The outcrop of this formation, its general topography and location of principal station facilities are shown on Figure 2.5.1-12. The Glen Rose Limestone was originally called the “Alternating Beds” because the outcrop pattern is characterized by stair-step topography resulting from differential weathering of impure, nodular limestones, softer claystone beds, and resistant, sparry-cemented, medium-to-thick bedded, hard limestones. The local order of occurrence or dominance of these lithologic types, plus other physical or paleontologic aspects, permits locally useful zonation as

shown on Figure 2.5.1-13 and on the lithologic cross section of the station vicinity shown on Figure 2.5.1-14.

The graphic lithologic log and the gamma-ray/resistivity log of boring P10 (Figure 2.5.1-13) illustrate a zonation of strata based on cores of all site boring logs, and related field information in the site vicinity.

Zone I, about 80-90 feet thick, is the bench-and-slope, uppermost outcrop unit indicative of major soft claystone beds alternating with hard, ledge-forming limestones. The basal claystone in contact with the underlying massive-bedded limestone of Zone II is the most prominent field contact visible throughout the reservoir area.

Zone II, 60-70 feet thick, is a massive unit of mostly nodular limestone with thin claystone partings best developed in the basal portion.

Zone III, 60-65 feet thick, is the most consistent unit recognizable in electric logs in the region. The upper part, IIIa, is an alternating claystone-limestone section transitional with the more massive units above and below; the lower part, IIIb, is the massive-bedded, bluff-forming Thorp Spring Member which is well exposed in the Paluxy River Bed at Glen Rose and further upstream.

Zone IV, at the base of the Glen Rose is about 30-40 feet thick; and consists of an alternation of claystone and limestone, both sandy or with thin sand lenses. The unit is transitional with the fine grained, calcareous, silty sandstone of the underlying Twin Mountains Formation.

The regional persistence of the Glen Rose zonation is indicated on the 25-mile correlation cross section (Figure 2.5.1-14) from the plant site east to Cleburne, Texas.

Where the Glen Rose beds are not exposed at the surface, data obtained from borings indicate that it is generally manteled by a few feet (range of a few inches to 15 feet) of surficial soils. These soils consist of mixtures of clay, silt and sand with some gravel and cobble-size rock fragments. In valley bottoms, the Glen Rose beds are overlain by alluvial sediments and residual soils which range to approximately 10 to 15 feet in thickness. As evidenced in many of the boring locations, weathering processes have produced a weathering zone on the Glen Rose up to several feet in thickness. This zone has been chemically altered, partially oxidized, and in some areas over 40 top 60 percent of the interval decomposed to a soil consistency.

The upper limit of bedrock, below which no soil-like inclusions were encountered in borings, is indicated on the vicinity Bedrock Contour Map, Figure 2.5.1-15. Bedrock contours in the immediate plant site are shown on Figure 2.5.1-16. Borings logs are presented in Section 2.5.5.3.

The conditions encountered at Category I facilities including the overburden and top of rock and moderately to severely weathered rock zone where it overlies the better rock are shown on geologic cross sections in Figures 2.5.4-40, 2.5.4-41, and 2.5.6-10. The section locations are shown on Figure 2.5.5-5. Pertinent information regarding foundation grades, existing groundwater conditions and characteristics of subsurface materials are summarized on these figures. The surficial rock generally is of a tan to orange-tan limestone which is occasionally dolomitic and fossiliferous. The remainder of the Glen Rose in this area consists of light to dark

gray argillaceous limestone with lenses and/or zones of gray to greenish-gray calcareous claystone. It is sporadically fossiliferous, dolomitic, pyritic and chrystalline. The unweathered Glen Rose is consolidated rock, medium hard to soft and thin-bedded to massive, becoming generally massive with fewer claystone zones below at approximately 770 feet in elevation. Oolitic zones are common in the massive portion of the formation. There are occasional zones which consist of limestone fragments enclosed in a claystone matrix, indicative of slump brecciation during deposition. In outcrops, the claystone lenses weather out to produce a thin-bedded appearance.

The Twin Mountains Formation underlies the Glen Rose Formation with a gradational contact. It was encountered in borings in the Station area at approximately elevation 610 to 615 feet. The sandstone beds of the Twin Mountains Formation constitute the aquifer for domestic water supplies and are collectively referred to in the region as the “Trinity Sand” [20].

In the postconstruction S/L cluster borings (Fig. 2.5.1-16), drilled for seismic crosshole survey, the Twin Mountain Formation was found to be about 250-ft thick and unconformably overlying the Mineral Wells Formation of the Strawn Series (Pennsylvanian age) at elevation 366 ft (Figure 2.5.4-30A). The Twin Mountains Formation is composed of sandstone and claystone, with occasional limestone layers [131]. The upper portion of this formation (above elevation 495 ft), as encountered in the borings, consists of interbedded sandstone, claystone, and argillaceous limestone. The sandstone is the dominant lithology. It is very soft to hard, friable in places, poorly cemented, light brown to light gray, and fine to medium-grained. The claystone and argillaceous limestone are medium hard to hard, dark gray to greenish-gray, occasionally green or maroon, and silty or sandy in places. The middle portion of the Twin Mountains formation (between elevation 495 and 458 ft) consists primarily of generally hard and brittle, reddish-brown, and highly slickensided claystone. The lower portion (below elevation 458 ft) is composed of interbedded sandstone and claystone. The sandstone is generally coarse-grained and occasionally conglomeratic, with infrequent fractures and common clay-rich intervals. Hard sandstone and claystone with up to 3-ft thick beds comprise the lowermost 20 ft of the formation. The presence of relatively unconsolidated sandstone and soft claystone in the middle and lower portions of the formation was indicated by the caliper logs of the S/L clusterly at elevation 489 ft (middle portion) and elevation 428 ft (lower portion). Poorly cemented sandstone was also encountered in borings P-9 and P-10 in which the drill rods rapidly penetrated some sandy zones due to easy cutting and/or jetting erosion by high-velocity drilling fluid.

The Mineral Wells Formation [130] was encountered in the S/L cluster Borings at elevation 366 ft, and was penetrated for 65 ft, exposing predominantly claystone beds. These beds, being of Paleozoic age, are distinguished from the similar overlying Lower Cretaceous beds by a higher degree of induration manifested in greater hardness and slickenside frequency, and by the occasional presence of vertical fractures filled with limestone. They are also characterized by their massive nature, dark color, and intercollated limestone seams and layers [131].

Figure 2.5.1-14 illustrates the approximate relationship of stratigraphy at the site to the stratigraphy found in borings within approximately five to 25 miles of the site.

The extensive limestone strata which are present at the site and vicinity are not subject to solutioning because of argillaceous impurities. There is no evidence of solutioning observed in the core obtained from the numerous borings. Fractures or joints occur infrequently.

A more detailed description of subsurface conditions is presented in Section 2.5.4.

2.5.1.2.4 Structure

Dip of the sediments in the site vicinity is to the east at approximately 25 feet per mile. Slight, gently warping of the sediments is occasionally evidenced in road cuts and natural exposures in the area surrounding the site. These are minor local features which are very limited in a real extent and degree of flexure. The infrequent slicken sides encountered in the Glen Rose Formation appear to be the result of differential settlement which occurred during compaction and diagenesis of the formation. The extensive investigations conducted at the site vicinity revealed no evidence of faults, shear zones or other anomalies.

Examinations of electric logs from recent gas exploration wells in the site vicinity suggests the presence of subsurface fault. The locations of these wells are presented on Figure 2.5.1-17. The faults locations are presented on Figure 2.5.1-23. Larger scale maps of the fault nearest the site are presented in Figures 2.5.1-23A, 24 and 26. This fault has no well cuts and is inferred from trends in subsurface data. The fault exhibits normal movement and is approximately 65 miles long (Figure 2.5.1-23). The throw on the fault appears to decrease upward until normal conditions are reached at a subsea datum of approximately 2,000 feet.

The faulting is associated with basement faulting. The structure model which accommodates this faulting is one of older faulting from basement movement which faulted the Ellenburger (see Section 2.5.1.1.4).

Later movement renewed the fault to cut the Marble Falls and Big Saline formations and continued upward into the Strawn but died out as the Strawn formation was deposited. There is no evidence of renewed movements after middle to late Strawn time (over 270 million years ago).

Figures 2.5.1-23A, 24A and 26 are the revised structure maps of the Ellenburger, Marble Falls and Big Saline formations. They are based on more data than was available for the maps filed with the initial FSAR. The current information does not indicate any faulting within five miles of the site. A structural nose trending southwest to northeast is present on the Ellenburger, Marble Falls and Big Saline horizons. No faulting is interpreted with this nose nor is any anticipated within five miles of the plant site. If by further hydrocarbon exploration any faulting is found within the five-mile radius, it is not expected that it will extend above a datum of approximately 2,000 feet subsea (approximately the middle or upper portion of the Strawn formation) [124]. On the Strawn marker structural map (Figure 2.5.1-28), no faulting is depicted within five miles of the plant site. Where a fault is mapped on older beds to the northwest of the plant (approximately seven or eight miles from the site) there is no faulting at the level of the Strawn marker. This indicates the faulting has died out in the Strawn Formation between the Big Saline Formation and the Strawn marker. Cross section A-A' (Figure 2.5.1-30) illustrates this upward limitation of the faulting. Cross section B-B' (Figure 2.5.1-31) illustrates the absence of faulting near the site.

Cross Section A-A^1 (Figure 2.5.1-30) is essentially a strike section on the Big Saline and older units as shown on Figure 2.5.1-23A. Cross Section B-B^1 (Figure 2.5.1-31) is a dip section of the Big Saline and older units (Figure 2.5.1-23A). In contrast, cross section A-A^1 (Figure 2.5.1-30) is a dip section on the Strawn marker and cross section B-B^1 (Figure 2.5.1-31) is a strike section (See Figure 2.5.1-28). The erosional top of the Ellenburger dips at about 100 ft/mi (1°) to the east and the Strawn dips at about 200 ft/mi (2°) to the northwest. These gradients reflect typical regional gradiens related to development of the Fort Worth Basin within the Texas platform. The gradients of 1-2° are not considered steeply dipping.

Figure 2.5.1-32 (Cretaceous Structural Map) presents the structural contours on the Paluxy Sand-Glen Rose Limestone contact over the 5-mile radius area and, over a smaller area, on the prominent marker bed about 75 feet below the top of the Glen Rose. Contouring on the marker bed is confined to the central portion of the site area in a 2- to 3-mile strip adjacent to the NW-SE trending valley of Squaw Creek. Elevations for datum control of contouring were taken from published USGS topographic quadrangles. The principal points of the Paluxy-Glen Rose contact were established in the field through road traverses; the upper Glen Rose marker bed points were in large part transferred directly from areal photographs to the topographic base (Figure 2.5.1-10, Vicinity Geologic Map).

Figure 2.5.1-32 shows a consistent north-south regional strike and constant dip to the east at a rate of about 25 feet per mile for both of these horizons. The mappable continuity of the Paluxy-Glen Rose contact and of the upper Glen Rose marker bed plus the structural contouring indicate no surface anomaly in the site area.

Structural cross sections C-C' and D-D' (Figures 2.5.1-34 and -35) supplement the structural maps and likewise indicate no evidence of post-Paleozoic faulting, known or inferred, west or northwest of the 5-mile radius area. The most significant subsurface Glen Rose datum is the massive Thorp Spring Limestone Member. The top of this high resistivity unit marks the boundary between Glen Rose zones IIIa and IIIb of the lithologic section at the plan site (Figure 2.5.1-13). All correlation lines extended from well to well, based on gamma-ray logs updip and self-potential/resistivity logs downdip, are essentially parallel to the Zone IIIa - Zone IIIb boundary (= top of Thorp spring Member). No faulting is indicated in either of the cross sections within the Cretaceous rocks.

2.5.1.2.5 Groundwater

Detailed information regarding site groundwater is described in Section 2.4.13.

2.5.1.2.6 Engineering Geological Evaluation

1. General

   Detailed discussion of engineering geological considerations in relation to specific seismic Category I structures is presented in Section 2.5.4.

2. Site Behavior During Past Earthquakes

   The response of the site to past seismic activity is discussed in Section 2.5.2.1, Seismicity. Although a few distant large earthquakes (1811-1812, 1882, 1931) have been, or could have been felt at the site, it is unlikely that the CPNPP site has experienced greater than Intensity III (less than 0.09 g) in historic time. Table 2.5.2-1 describes the earthquake intensity scale. Detailed onsite studies have not disclosed any physical evidence to indicate that the site has experienced major seismic activity at any time. These studies included a detailed survey of the site vicinity in order to detect any features that could be related to major seismic activity such as sand dikes, intrusions, scarps, or dissimilar materials placed into juxtaposition. No such features were found during the preliminary investigations and no such features were found during the excavation of the site.

3. Stability of Subsurface Materials

3.1 Uplift and Subsidence

3.1.1 Uplift

Tectonic tilting or warping is not characteristic of this region; hence, significant uplift or subsidence due to such phenomena will not occur. No evidence of actual or potential uplift or subsidence was revealed at the site.

3.1.2 Subsidence

3.1.2.1 Solution Potential

The limestone of the Glen Rose Formation is the only calcareous material in lateral or vertical proximity to the site. The thin-bedded and impure nature of this rock renders it unfavorable for the development of solution cavities. Study of topographic maps and areal photography and examination of rock cores shows no indication of karst formation or other solution activity in the area. In addition, detailed onsite reconnaissance has failed to find any evidence of sink holes or solution cavities. The absence of such features was confirmed in interviews with federal civil construction agencies.

Many of these agencies have had experience with the Edwards Limestone, but this data can be applied to the Glen Rose formation because the Edwards is purer limestone than the Glen Rose and is more susceptible to solution activity. If there has been no reported solution activity in the Edwards, it can be conservatively assumed that the Glen Rose will have no solution activity.

The chief geologist of the Fort Worth District of the Corps of Engineers reports that solution voids have never been encountered in the corps drilling in the Edwards Limestone near the Balcones Fault Zone (Wallis Samuelson, personal communication). The Texas Water Development Board and United States Department of Agriculture Soil Conservation Service have no record of solution activity in the Cretaceous limestones in the site vicinity (Gunner Brune, personal communications). The Texas State Board of Economic Geology reports no accounts of solution problems in the Glen Rose Limestone [43].

The results of the petrographic and chemical analysis of the Glen Rose Formation show that the limestone has very low porosity, poor sorting and slight to moderate compaction, all of which are indicators of low permeability. In addition, there was no evidence of styolites, pressure solution of grains, or collapse structures of any scale noted in the thin section analysis. The rarity of dolomite as reported from petrographic and X-ray analysis suggests that collapse structures have not occurred from the effect of volume change in the transformation of Mg-calcite to dolomite

and calcite. The low amount of magnesium shown in the chemical analysis indicates that the magnesium is already in the dolomite phase and that future dolomitization as an isochemical reaction is impossible.

These laboratory tests indicate that the Glen Rose Limestone should have a very low permeability, an indication which is confirmed by the packer test data presented in Table 2.5.6-1. The laboratory data also indicates that future solutioning of the limestone should not occur.

Considering the various material types, chemistry, distribution and site environment, it is concluded that solutioning activity in the limestones beneath the site does not exist. Results of detailed petrographic and chemical analysis of the limestone below the site indicate that the potential for solutioning is very low. Detailed results of these tests are given in Section 2.5.4.2.3.

At a considerable distance east of the site vicinity, anhydrite and gypsum and present in Glen Rose Formation [10]. Under certain conditions such material could be subject to solutioning. However, these conditions are not known to occur near the site.

3.1.2.2 Oil and Gas Wells

The Paluxy and Glen Rose formations are major lower Cretaceous hydrocarbon producing reservoirs in the East Texas Embayment. These reservoirs are mostly east and south of the Luling-Mexia-Talco Fault Zone [44] and are nearly 100 miles east of the site. Erratic sands in the Pennsylvanian Strawn, and the Ordovocian Ellenburger limestone are major producing zones in the Bend Arch area 25 to 50 miles or more to the west.

No exploratory or producing oil or gas wells existed within five miles of CPNPP prior to 1974. At that time, three exploratory wells have been drilled in that area and all three were reported as dry and abandoned. The first area production was reported early in 1977. In light of new data, a study of mineral potential was performed by H. J. Gruy and Associates, Inc. and is presented here.

Using the subsurface geologic terminology established by Gulf Energy and Minerals Co. -U. S. No. 1 Otis Rollins well in the Louis Boatwright Survey A-33, Hood County, there are four Paleozoic formations having the potential for hydrocarbon production in the area of the CPNPP. In ascending order, these are the Ellenburger Formation, the Marble Falls Formation, the Big Saline sandstone and the Strawn sandstones. The size of a possible blowout from the above listed formations is in the order they are listed (i.e., maximum in the Ellenburger and minimum in the Strawn sandstones). The probability of finding hydrocarbons is in the reverse order as listed. In the following discussion, wells which fall within a five-mile radius of the plant site are listed with a well identification number keyed to Tables 2.5.1-5 through 2.5.1-10 and to Figure 2.5.1-17

entitled “Natural Gas and Oil Pipelines and Wells Within Five Miles of CPNPP”. As noted on this Table, all hydrocarbons produced within five (5) miles of the site are believed to be from stratigraphic traps not structural traps [124]. The outline on the net hydrocarbon isopachous (Figures 2.5.1-25, 27 and 29) maps which represent the size of the hydrocarbon accumulations do not appear to be structurally controlled.

A structure map (Figure 2.5.1-23) on the top of the Ellenburger formation was constructed for Somervell, Erath, Hood, Johnson, Hill Bosque and Hamilton counties. All wells (for which there were public records) that reached the Ellenburger Formation were used in this study. There is no structural high on the Ellenburger under or adjacent to CPNPP.

Within the studied area, only two wells produced from the Ellenburger Formation. The Cities Service No. 1 Foss, approximately 23.5 miles northwest of CPNPP in northeastern Erath County, is indicated by completion card information to have an initial potential flowing of 196 barrels of oil per day from Ellenburger perforations at 5,065 to 5,076 feet. No state production records exist confirming this production. The second well is the HNG Oil Company No. 1 Ryan well in the northeastern corner of Hamilton County, approximately 25.2 miles to the southwest of the plant site. This well reported an initial potential pumping of 28 barrels of oil and 41 barrels of water per day from Ellenburger perforations located at a depth of 4,423 to 4,434 feet. The total cumulative production of this well from state records is 1,571 barrels of oil, and the well has been shut in since June 1976.

Electric well log analysis was performed for the Ellenburger Formation in seven wells. A summary of the calculated petrophysical properties is presented in Table 2.5.1-7. The nearest well testing the Ellenburger Formation (approximately 2.4 miles northeast of the plant) is the Dallas Production Company No. 1 Hubbard (Well I. D. No. 14) in Hood County. The No. 1 Hubbard tested salt water from the Ellenburger Formation. A well approximately 5.9 miles southwest of the plant site, the Dorchester Exploration No. 1 Davis-Bonney well, calculated 45 feet of net hydrocarbon pay by electric well log analysis in the Ellenburger Formation. This well was not tested nor was completion attempted in the Ellenburger Formation.

The Dorchester Exploration No. 1 Davis-Bonney well located approximately 5.9 miles southwest of the plant site is currently plugged and abandoned. Records from the Oil and Gas Division of the Texas Railroad Commission show that it was plugged on March 6, 1975.

The Ellenburger does not possess hydrocarbon potential under or adjacent to the CPNPP. This is supported by the test of salt water in the closest well to the north and the location of the plant site in a structurally low position as mapped on the top of the Ellenburger Formation.

The structure map (Figure 2.5.1-24) of the top of the Marble Falls Formation indicates no structural high under the site. There is Marble Falls gas production reported to the west and northwest of the plant site with the nearest gas well, the Ben J. Taylor No. 1 Cravens “B” (Well I. D. No. 22), located 2.5 miles to the northwest of the plant site. Marble Falls gas production is associated with a structural high, trending from southwest to northeast, to the west of the plant site. A net hydrocarbon isopachous map (Figure 2.5.1-25) has been prepared for the Marble Falls Formation. An area of thick net hydrocarbon exists approximately 4.3 miles to the west of the plant site. The maximum net hydrocarbon thickness calculated from electric well log analysis is 62 feet. This net hydrocarbon isopachous map indicates a rapid thinning to the east, and we postulate that under CPNPP there will be zero feet of net hydrocarbon porosity found in the Marble Falls Formation.

The structure map (Figure 2.5.1-26) on the top of the Big Saline sandstone portrays a structural high, trending from southwest to northeast, to the west of CPNPP. The Comanche Peak site is low on the east flank of this trend and on the east flank of the regional dip into the deeper portion of the Fort Worth Basin. The nearest producing well reportedly completed in the Big Saline sandstone is the Tri-Venture II No. 1 Nelon (Well I. D. No. 18), located approximately 3.2. Miles to the west-northwest of the plant site. A net hydrocarbon isopachous map (Figure 2.5.1-27) of the Big Saline sandstone was prepared. Fourteen feet of net hydrocarbon-bearing porosity was calculated by electric well log analysis for this zone in a well approximately 4.4 Miles to the west-northwest of the plant site. The net hydrocarbon isopachous map of the Big Saline sandstone indicates a north-northeast to south-southwest trending thick area approximately 3.8 Miles to the west of CPNPP. The Big Saline sandstone zone thins and loses porosity to the east and southwest. This loss of porosity lessens the probability of any production from the Big Saline sandstone under CPNPP.

A structure map (Figure 2.5.1-28) of the top of the Strawn Marker indicates a northwestward dip at a uniform rate interrupted by minor anomalies. An isochore map from the top of the Strawn Marker to the top of the Big Saline sandstone indicates an eastward thickening of the Strawn Formation into the deeper part of the Fort Worth Basin. As the overall zone thickens, there is a loss of both total number of sandstones and porosity. This results in a reduction in the calculated net hydrocarbon pay sand in the Strawn Formation.

All sand lenses in the Strawn Formation have been combined into one net hydrocarbon isopachous map (Figure 2.5.1-29) because of the lenticularity and limited drainage of any individual sand within the Strawn Formation. The maximum net hydrocarbon pay thickness calculated in a well from electric well log analysis was 43 feet. The net hydrocarbon isopachous map of the Strawn Formation indicates a north-south trending area of hydrocarbon-bearing sandstone approximately 3.8 miles west of the plant site. The nearest well completed in the Strawn Formation is the Gulf Oil No. 5 Bratten Ranch (Well I. D. No. 15), 4.4 Miles to the west of CPNPP.

Towards the plant site the Strawn sandstones thin, become tighter and undergo a facies change into a shaley equivalent. Some Strawn sandstone gas production may be achieved adjacent to the boundaries of the Exclusion Area and even near or under the plant site. However, it is evident that less than 20 feet of net hydrocarbon Strawn will exist within the Exclusion Area and any gas well would be marginal to subcommercial.

A well was drilled within the boundaries of the Squaw Creek Reservoir. The data on this well can be found under Well I. D. No. 24 listed in Table 2.5.1-5. This Well was plugged under the supervision of a Texas Railroad Commission representative in June 1971. Table 2.5.1-5 lists pertinent data for the wells within a five-mile radius of the plant site.

Eighteen wells in the Strawn sandstones, three wells in the Big Saline sandstone, eight wells in the Marble Falls Formation and ten wells in the Ellenburger Formation were selected for study of petrophysical properties. The distance of the studied wells was from 2.4. to 33.3 Miles from the plant site. The results are summarized in Table 2.5.1-6. Water saturations, porosites and net hydrocarbon thicknesses were calculated from electric well logs. The reservoir pressures, temperatures and gas gravities are known only for a few wells.

Table 2.5.1-7 is derived from Table 2.5.1-6 and is a statistical summary of reservoir properties. For each zone, the minimum, the maximum and the average values of net hydrocarbon thickness, porosity, water saturation and permeability are listed. The permeability values are obtained from radial steady-state flow calculations on tested wells.

For each possible producing zone, a maximum hypothetical well is postulated with maximum bottom-hole pressure and optimum valves for net hydrocarbon feet, porosity and water saturation. The absolute open flow potential is calculated for each zone using radial steady-state gas flow calculation. The results are shown in Table 2.5.1-8.

The maximum absolute open flow potential for an out-of-control well (blowout) of 43,800 thousand cubic feet of gas per day is calculated for a hypothetical Ellenburger well using 1.5. times the maximum permeability. This rate is 3.21 times the rate of 13,360 thousand cubic feet of gas per day calculated for the average Ellenburger well. The maximum subsidence of 0.54 feet is calculated for the hypothetical Ellenburger well at depletion. This subsidence extends outward approximately 2,250 feet from the wellbore. In this subsidence calculation, it is assumed that the zone above the producing Ellenburger is not compressible.

The gas gravity data on six wells (Table 2.5.1-6) indicate a range of 0.69 to 0.70. Data was available only on these six wells within the study area.

Reservoir data on some selected wells within the five-mile radius from the plant site are shown in Table 2.5.1-9. Table 2.5.1-10 presents calculations of the gas in-place for a hypothetical well in each formation.

The Marble Falls and the Big Saline formations produce by depletion drive. Depletion drive is associated with minimal to no water production. The Strawn sandstones do have some associated water production. Gulf Energy & Minerals Co.-U.S. (the major operator in the area) does have a water disposal well located seven miles northwest of the plant site. This well is the Gulf Energy & Minerals Co.-U.S. No. WD-2 T. H. Nix located in the Lewis Boatwright Survey A-33, southern Hood County, Texas. Water is being injected for disposal in the Ellenburger formation from 5,550 to 5,796 feet. This well was completed on October 10, 1977.

Water production associated with the hydrocarbon production from the Strawn sandstones within five miles of the plant is minimal. The Strawn sandstones are lenticular with low porosities and, although small amounts of water are produced, the reservoir drive mechanism is primarily a depletion drive, not a water drive. The Strawn sandstones are competent sandstones, and fracturing is usually necessary to achieve gas production. There is little or no potential subsidence due to production of hydrocarbons and water from the Strawn sandstones.

The water production as reported by Gulf Energy & Minerals Co.-U.S. to the Railroad Commission of Texas on Form G-10 for the test period of October, November and December, 1977 is summarized as follows:

Field	Formation	Number of Wells	Average Water Production in Barrels per Day per Well
Bratten Ranch	Marble Falls	3	8
Bratten Ranch	Big Saline	1	4
Bratten Ranch	Strawn	4	7
McIntosh	Big Saline	1	35
McIntosh	Strawn	5	8
Otis Rollins	Marble Falls	1	1

The hydrocarbon production to the northwest of the plant site is from the above-listed fields.

In summary, the new data on mineral potential support the data available prior to 1974. On the basis of calculations and the consolidated nature and integrity of the rock, no measurable subsidence is anticipated from depletion of the recorded or future (postulated) gas reservoirs.

3.1.2.3 Groundwater and Geothermal

Groundwater withdrawals, in the event they would be greatly accelerated from any of the aquifers underlying the site, should not lead to a subsidence problem. The formations are sufficiently well consolidated and structurally of a nature that the potential for surface subsidence is virtually nil.

Sedimentary strata under the site are indurated or semi-indurated. The semi-indurated strata are composed of poorly graded granular materials which are not subject to change in volume upon dewatering. The United States Geological Survey in Austin, Texas, reports that subsidence of Cretaceous sandstones in the site vicinity has never been observed and is highly unlikely to ever occur (Al Winslow, personal communication). The United States Geological Survey in Fort Worth, Texas, also has no knowledge of subsidence in Cretaceous sandstone in the site vicinity. (John Montgomery, personal communication).

An estimate, based upon conservative consolidation characteristics, has been made of the potential subsidence of the site area due to a conservative drip of 220 feet in the piezometric level in the Twin Mountains Formation.

This estimate of potential subsidence was based upon a consolidation test performed on a sample of the Twin Mountains Formation, the results of which are presented on Figure 2.5.1-21. This sample was taken from uncemented sandstone zone with one of the lowest RQD (Rock Quality Designation) values and which is considered to be more compressible than the other strata within the Twin Mountains Formation. The method and results of the settlement calculation are presented on Figure 2.5.1-22. The settlement obtained from this calculation is very conservative due to the assumption made that the entire Twin Mountains formation has the same compressibility as the sampled tested. Based upon an evaluation of boring logs, it is estimated that actual subsidence under the conservatively assumed 220 foot drawdown would be less than one-half the value calculated or about six inches.

Considering the site geology and the regional potential for groundwater withdrawal, it is unlikely that the site will experience any subsidence at all during the life of the plant. Even if subsidence did occur, it would be limited to a few inches, be regional in nature (i.e., no differential subsidence) and have no effect on the plant operations.

There are no known existing or potential geothermal energy locations near the site. Geothermal energy can be inferred by existence of hot springs, or the distribution of young volcanic rocks [45]. Neither of these are present near the site; the nearest known higher-than-average thermal gradient is at Marlin, Texas, nearly 100 miles to the southeast. Here water at a temperature of 147°F has been found in deep wells. The geothermal

gradient in the site vicinity is insufficient for any consideration to be given to the use of geothermal energy.

3.1.2.4 Reservoir Effects

The increase in earthquake hazards at the site due to the creation of the SCR is negligible. Most theories on the cause of reservoir-created earthquakes attribute the cause to lubrication of preexisting faults under the reservoir sites [46 and 47]. Because there are no known faults within five miles of the site, the potential for reservoir induced earthquakes is considered nil. This conclusion is reinforced by the fact that no reservoir-induced earthquakes have been reported for the two existing reservoirs which are in close proximity to the site and in similar geologic systems. These are Lake Granbury and Lake Whitney whose locations are shown on Figure 2.4-5.

A subsurface fault has been identified approximately 7 miles NNW of the Class I structures as identified on Figures 2.5.1-23, 23A, 24, and 26. A cross section through this fault is shown on Figure 2.5.1-30. This fault is mapped at the Ellenburger, Marble Falls and Big Saline horizons; however, it cannot be traced upward beyond the middle portion of the Strawn formation. Based on all available data, it appears that this fault dies out upward in the middle to upper portion of the Strawn formation (over 270 million years old) [124]. No actual cut of the fault has been found in any well, and the faulting is inferred from the subsurface data established by the well control.

Other known faults in the site area exhibit this same dying out upward in the middle to upper portion of the Strawn formation [124]. Based on this evidence, any other presently unknown faulting which might exist under the plant site or under the Squaw Creek reservoir would occur only in beds older than middle to upper Strawn [124]. There appears to be no potential for hydraulic interconnection through any existing or future wells with the faulted strata. The only formations with any significant aquifer potential are the Ellenburger and Hickory. Faulting in the area does not have sufficient displacement to place the Ellenburger or Hickory in communication with younger porous formations (see Figure 2.5.1-30). The formations above the Ellenburger have discontinuous lenticular porosity. Therefore, the potential for any hydraulic interconnection by faulting with other porous and permeable strata is minimal.

Table 2.5.1-11 has been constructed from a representative sampling of the wells on which drill-stem tests and production test data are available. These data illustrate that no geopressures (only normal pressures) are found in the Ellenburger, Marble Falls, Big Saline formations or Strawn sandstones.

Due to the indurated and consolidated nature of the Cretaceous rock at the site, subsidence of any significance due to the reservoir load is not considered possible. Minor elastic-deformations of the rock may occur;

however, due to the relatively shallow depths of the reservoir these deformations will be negligible.

Due to the low permeability of the limestones and the lack of solution potential of the Creataceous deposits in the site vicinity, the potential for solutioning due to reservoir seepage is considered negligible.

Result of petrographic and chemical analyses of the Twin Mountains Formation indicate that the solution potential of the sandstone is very low. Results of these tests are presented in Section 2.5.4.2.3.

Piezometric data indicate that the Glen Rose Formation contains a perched water table and that the Twin Mountain Formation will not be hydraulically connected to the new reservoirs.

Seepage from the reservoirs should be minimal because the jointing in the Glen Rose limestone is not continuous (see Section 2.5.1.2.6); also the Glen Rose has been shown to maintain a separate piezometric level and the solutioning potential of the limestone has been demonstrated to be very low.

3.2 Deformational Zones

Joint patterns in bedrock have been observed both on areal photographs and in the field. No evidence for movement along joints (i.e., faulting) has been observed, however.

Strikes of the primary joint systems are N20 E and N78 W, as measured in river bottom exposures. The degree of weathering in even the more resistant rock types obscures joint patterns both in road cuts and in natural exposures away from the river channels. The surface joints are generally spaced several feet apart and either are opened or filled with soil, vegetation and small weathered rock fragments.

The joints in the limestone do not extend into the overlying and underlying claystone beds (O. T. Hayward, personal communications). Residual boulders of the massive Thorp Springs limestone near the base of the Glen Rose Formation are present in the Paluxy River bed near Glen Rose. These boulders are the combined result of rock structure joint sets intersecting at right angles and weathering processes. These perched boulders are strictly a surface phenomenon [55].

Part (b) of Figure 2.5.1-18 shows a rosette diagram of the strikes and frequencies of observed structural trends in the lower half of the Paluxy basin. To varying extents over the region these alignments influence the courses of stream channels, as illustrated in part (A) of the figure. Emphasis was placed on field checking of alignments in the site vicinity to determine whether evidence existed for faulting.

No evidence for faults or shear zones was revealed within a five-mile radius of the site, either in the regional or the site studies.

The origin of the joints is not a question easily resolved. The north-northeast trending system coincides with directions of the Balcones and Luling-Mexia-Talco fault systems to the east so that the possibility of a relationship could not be completely dismissed.

Considerable topographic relief was established on the pre-Cretaceous (Wichita) peneplain surface (Figure 2.5.1-19) prior to burial by Cretaceous sediments. It is probable that subsequent differential consolidation of the covering sediments resulted in some stresses which led to the formation of joints and occasional slickensides which were observed in borings at the site. The same phenomenon of compaction and consolidation probably warped the regional dips slightly into very gentle folds which are known to occur sparingly throughout the vicinity.

On a broader scale, the crossing of tectonic axes resulting from conflicting compressional forces created areas of fracture and distortion throughout Texas and Oklahoma [34]. This is best illustrated in the Arbuckle Mountain area where the Wichita axis intersects the Ouachita axis. The site is distantly removed from intersections of tectonic axes.

3.3 Alteration, Weathering and Structurally Weak Zones

Results of detailed site investigations revealed no zones of alteration, irregular weathering profiles or zones of structural weakness which would adversely affect the stability of the Station facilities. General excavation to the Station grade of elevation 810 feet MSL will result in removal of essentially all weathered material.

3.4 Unrelieved Residual Stresses in Bedrock

The tectonics of the area indicate that there should be no abnormal stresses due to active tectonic forces. It is not felt that stress measurements are required to confirm this opinion.

3.5 Geologically Hazardous Materials

The occurrence of anhydrite in certain geologic formations in Central Texas has led to violent explosions and uplifts due to the hydration of the mineral to gypsum. The reaction is accompanied by great pressure and an increase in volume. Figure 2.5.2-10 shows the location of outcrops which contain critical amounts of anhydrite and/or gypsum.

The deposits, generally of Permian age, usually take the form of anhydrite at depths greater than 500 ft. Between the depths of 100 and 500 feet, either anhydrite or gypsum can occur, while gypsum normally is found at depths less than 100 feet. Erosion reduces the overburden, permitting groundwater to reach the anhydrite and convert it to gypsum. Mean annual precipitation is less than 30 inches where outcrops of gypsum and gypsiferous material occur. The site is distantly removed from all historic uplifts of this type.

The areal distribution of expansive soils in the region is illustrated on Figure 2.5.1-20. It is not anticipated that materials of a swelling character will have any adverse effect upon structures at the site whose foundations are constructed below the soil zone.

3.6 Effects of Man's Activities

Except for the removal of minor quantities of sand, gravel and dimension stone in the site vicinity, no mining has occurred. In connection with plant operation, it is anticipated that a water supply will be developed within wells on the order of 600 gallons per minute from the Twin Mountains Formation. This pumpage may eventually reduce the artesian pressure in the area, but withdrawal of groundwater will have no deleterious effect on rock deformation or stability. Extraction of subsurface fluids is discussed in Section 2.5.1.2.6.

4. Physical Properties of Geologic Materials

The results of onsite geophysical surveys and laboratory testing are provided in Section 2.5.4.4.

5. Safety Criteria

Safety criteria are discussed in detail in Sections 2.5.4.10 and 3.7.

2.5.2 VIBRATORY GROUND MOTION

Vibratory ground motion and the design earthquake (Safe Shutdown Earthquake) are evaluated in consideration of:

1. A study of the seismic history of the region;

2. A study of the geology and tectonics of the region;

3. The relationship of seismicity to geology; and,

4. The response of the site to both the Safe Shutdown Earthquake and Operating Basis Earthquake.

Regional and site geology are describe in Sections 2.5.1.1 and 2.5.1.2

2.5.2.1 Seismicity

The earthquake history of Texas has been poorly documented in the past. This result has been due, in part, to the recognized low seismicity of the area, the lack of seismograph instrumentation for recording events, a generally sparse population and insufficient interest in minor seismic activity. The new Texas earthquakes of consequence occurred in areas where there was little damage to the works of man. Except for the interest of the academic community and petroleum geologists, all but the larger events probably would have remained unreported.

Improved instrumentation in recent years and the increased awareness of geotechnical professionals of geologic and other environmental hazards has resulted in an apparent increase in reports of seismic activity. Consequently the increase in reports probably do not reflect an actual increase in seismic events. Some reports may be due to blasting, sonic booms, water flood operations in oil fields, or reservoir loadings of large dams.

Central and East Texas lie within the zone of least seismic activity in the United States. According to Algermissen and Perkins' (1973) Seismic Risk Map of the United States, the region lies within a Zone 0 (no damage) area [64] as indicated on Figure 2.5.2-1. King, using Woollard's [24] data, indicates an average of less than one epicenter per 10,000 square kilometers. This evaluation is based on reported and instrumentally detected epicenters for about 200 years and relies, necessarily, on incomplete data.

Texas was sparsely populated before 1820, but by the time Texas became a Republic, there were widely scattered ranches and settlements which would have reported larger events such as the Bonham, Texas earthquake of 1882. It is likely that all Modified Mercalli Intensity VII earthquakes in Texas have been reported for the past 150 years. The complete record for smaller events is shorter. A list of the earthquakes in Texas and adjacent areas of interest is presented in Table 2.5.2-2. Figure 2.5.2-2 shows the epicenters with respect to regional tectonic provinces.

The literature of Texas seismicity reflects a scarcity of recent damaging shocks, or even widely-felt shocks. No Texas earthquake with an intensity greater than VI has been reported east of the 100th meridian since 1882. Sporadic damaging events have occurred in Texas through the years; the most recent was in 1969 (Intensity VI, in West Texas. Sketchy field reports are available for most of the larger events. The few large West Texas shocks in the 1930's warranted field investigations and reports.

Seventeen seismic events (or series of events) have been reported with epicenters within 200 miles of the site (1882-1975). Three events (or series of events) are within 100 miles of the site. The closes known event to the site occurred 90 miles to the north in 1950 and exhibited an intensity of IV. Two events occurred 90 to 100 miles to the southeast of the site in 1932 (V-VI) and 1970 (IV) respectively. The highest reported intensity within 200 miles of the site was a Modified Mercalli Intensity VII exhibited by both the 1882 Paris and 1891 Rusk events located 155 and 160 respectively from the site.

The localized areas where seismic activity is observed to cluster are apparent (Figure 2.5.2-2). The El Reno, Oklahoma area located 200 miles from the site has been the locus of significant seismic activity. The most important event in this area occurred in 1952 with an intensity of VII and produced an intensity I-III at the site [27].

The central and northern Panhandle region of Texas 280 miles northwest of the site is also the locus of significant clustering of seismic activity and the 1936 Borger intensity VI earthquake [114].

Earthquakes of the south central region of the United States generally occur as single major shocks usually with associated smaller aftershocks and foreshocks. Occasionally, seismic energy release takes place in the form of earthquake swarms such as the earthquake series observed for the Sabine Uplift in 1964 or the recent 1974 Arkansas swarm. Swarm activity is not unusual in the eastern and central United States.

Both Rossi-Forel and Modified Mercalli intensities are used to describe the effects of historic earthquakes (see Table 2.5.2-1). A comparison of these intensity values with other commonly used intensity scales follows.

U.S.A. Modified Mericalli (M.M.) 1931	Japanese (JMA) 1950	Rossi-Forel (RF) 1873	European (Mercalli-Cancani-Sieberg) 1917
I	0	I	I
II	I	I-II	II
III	II	III	III
IV	II-III	IV-V	IV
V	III	V-VI	V
VI	IV	VI-VII	VI
VII	IV-V	VIII-	VII
VIII	V	VIII+-IX	VIII
IX	V-VI	IX+	IX
X	VI	X	X
XI	VII	X	XI
XII	VII	X	XII

A detailed description of individual earthquakes which have occurred in the area and which are considered to be relevant to this study for the purpose either establishing the SSE or to further illustrating possible tectonic relationships is presented below.

2.5.2.1.1 1882, October 22 - Bonham (Paris), Texas Earthquake

Intensity VII [26]: “About 4:15 P.M. an earthquake was felt in northern Texas, western Arkansas, and eastern Kansas, and presumably in the intervening portions of the Indian Territory. The region affected extended from Greenville and Paris, Texas and Little Rock, Arkansas northeasterly to Wichita and Leavenworth, Kansas, a distance of some 300 miles. The shock was reported from numerious places with these boundaries, and also, as a light shock, from Warrenton, Missouri, which is father eastward...no damage was done other than overturning movable articles and knocking bricks from chimney tops.” The original epicentral location was assigned at 35°N, 94°W [28]. Dockekal [69] has recently revaluated the effects and characteristics of this earthquake. Based on a reinterpretation of the original references, he relocates the epicenter 107 miles to the southsouthwest in the vicinity of Bonham and Paris, Texas. Accordingly, this event will be called the Bonham, Texas earthquake in further discussions. Intensities of MM VI-VII and MM VII for this earthquake are given by the USC & GS [70] and Docekal [69] respectively.

2.5.2.1.2 1891, January 8 - Rusk, Texas Earthquake

The original listing of this event was apparently by Milne [28], who used the London Times of January 10, 1891 [71] as his source.

> The Times account read:
>
> Rusk, Cherokee, Co., Texas -
>
> "Two sharp earthquake shocks were felt here yesterday. Chimneys were thrown to the ground and people awakened by the violence of the oscillation." - Reuter

Another account was the following from the Dallas Morning News, January 9, 1891 [72]

> Rusk, Texas - "Last night at 12:00 this town and immediate vicinity experienced two well defined shocks of a seismic nature. Each paraxym was accompanied by a detonation loud and long as thunder rolling from south to north. Several chimneys were levelled to the earth and sleepers in various portions of town were awakened. J.W. McCord, in charge of the county jail, a very strong structure, declares that for one full minute he apprehended a collapse of the building. Thos. Miller said the Acme Hotel was shaken to its foundation. During these disturbances there was a slight rainfall and some electrical force prevailing, but not of sufficient strength to produce the shock. A few parties here who were through the Charleston shocks of 1886 pronounced the phenomenon last night a genuine earthquake."

The above account, with some deletion, was also found in the San Antonio Express, January 9, 1891 [73]; the Galveston Daily News, January 9, 1891 [94]; the Houston Daily Post, January 9, 1891 [75]; the Fort Worth Daily Gazette, January 9, 1891 [76]; and the Terrell Times-Star, January 17, 1891 [77].

The only other original account seems to be the following from the January, 1891 edition of the Victoria Advocate: "It was for Rusk to furnish a long felt want in Texas, which it did on the 8th last. There was a genuine earthquake there which overturned chimneys, rocked buildings and shook up the city generally. Texas will not be outdone".

Eppley [78] has assigned an intensity of MM VII to this event based on an interpretation of Milne's Catalog of Destructive Earthquakes [28], and on the reports of chimneys being thrown down, which is one criterion of MM VII intensity. However, the original accounts are generally inconclusive and completely confined to the immediate vicinity of Rusk, which had an overwhelming lack of supportive data from the surrounding area and contained over 60,000 residents (22,975 in Cherokee County, 19,360 in Houston County, and 20,923 in Anderson County - 1890 census figures). This is contrasted with the felt area and damage reports from the October 22, 1882 Bonham (Paris) Earthquake (MM VII) (see Figure 2.5.2-3) which attracted accounts from numerous surrounding communities and was felt over an area of 135,000 to 195,000 square miles [78]. Given the felt area for the MM V quakes, reports of an MM VII quake would be expected from many surrounding towns rather than just from the town of Rusk.

The 15 January 1891 edition of the weekly Jacksonville Banner stated "Rusk claims to have felt an earthquake last week." In spite of the fact that Jacksonville is only 12 miles north-northwest of Rusk, the town obviously felt nothing.

Eastern Texas experienced very violent weather conditions during the period January 6-8, 1891. Tornadoes were reported in Queen City, Cass County and Halletsville, Lavaca County, and severe thunderstorms, heavy rainfall, and flash flooding was common. The damage reports in Rusk included damage to chimneys and two tall buildings, the Acme Hotel and the jail, which were one block apart. The damage reports are suggestive of a localized tornado or funnel-cloud that possibly did not quite touch down and furthermore, such a phenomenon would not have been observed at midnight.

The January 8, 1891 Rusk event probably was not an earthquake, but a localized tornado, which would be consistent with the recorded regional weather patterns of that two day period [120]. For the purpose of safe shutdown earthquake determination, however, the event will be treated as an earthquake.

2.5.2.1.3 1930, October 19 - Donaldsonville, Louisiana Earthquake

The October 19, 1930, Donaldsonville Earthquake is the largest reported earthquake to have occurred in the Gulf Coast. The earthquake was not recorded instrumentally in the area. Both the New Orleans, Louisiana and Springhill, Alabama seismograph stations were not recording at the time. The Georgetown University Observatory in Washington, D.C., recorded an earthquake at 6:22 CST. This may have been the Donaldsonville event.

The following sources have been examined regarding this earthquake:

Source	Origin Time	Epicenter Location	Felt Area (Sq. Mi.)	Maximum Intensity
U.S.C.G.S.- Memo to H.F. Reid [24]			12,000	V-VI (RF)
Neumann Ethq. Notes [80]			900	V-VI (RF)
			V (RF) Area	
Reid, H.F. (Notes, File) [24]	06:15:20	30N, 91W	V-VI (RF)	
Neumann & Bodle U.S.C.G.S. [8]		30N, 91W	15,000	V-VII (RF)
Branner & Howell Arkansas Geolgoical Survey [82]			12,000	
Docekal, [69]	06:17	30.08N 90.97W	18,500	VI (MM)
Coffman & Von Hake [83]	06:17	30.0N 91.0W	15,000	VI (MM)
	(RF) Rossi-Forel		(MM) Modified Mercalli	

Regarding this earthquake, Neumann [24] states, “The outstanding feature of the Louisiana shock was the irregular distribution of intensity in the Central zone and the relatively large area of the zone.” Neumann states that these features would probably indicate a deep-seated origin.

Neumann considered the region of greatest disturbance to be an area of about 900 sq. mi. including parts of Assumption, Saint Martin, Iberville, Ascension, St. James, and Lafourche Parishes. Neumann’s isoseismal map is shown in Figure 2.5.2-4. As can be seen, the intensity V (RF) isoseismal includes towns recording intensities of III (RF). An area of 12,000 sq. mi. is included in the IV (RF) isoseismal. Here also are found towns reporting intensities of III (RF) to VI (RF).

A possible explanation for this irregularity of distribution in ratings may be that parts of the affected area contained buildings constructed of poor masonry. Many areas in southern Louisiana are underlain by relatively weak alluvial soils with high ground water conditions. It is interesting to note the sequence of intensity ratings north and south of the intensity V (RF) isoseismal along the Mississippi River. The higher values are found along the river to the north.

The maximum intensity assigned to the Donaldsonville Earthquake has increased over the years. Initially, Neumann [24] assigned a maximum intensity of VI (RF). This corresponds roughly to a MM V-VI. Reid also recorded the maximum intensity as VI (RF) [24]. The official USCGS publication, “U.S. Earthquakes of 1930” by Neumann and Bodle [81], does not give a maximum intensity rating per se but lists the towns of Donaldsonville, Napoleonville, White Castle, Franklin, Morgan City, and Allemands as intensity V (RF) to VII (RF). Docekal [69] and the most recent catalog of NOAA (83), give the value of MM VI.

Damage reports appearing in USCGS, the “Donaldsonville Chief” (84), the “Baton Rouge Times” [85], and the AP wire of October 20, 1930 have been reviewed. The greatest damage occurred in the towns of Gonzales and Napoleonville. These two towns are north and south of the Mississippi (a distance of 12 miles, respectively. At Gonzales some chimneys were cracked almost from top to bottom. Parts of others above the roofline were knocked off. This was reported by Assessor J. Paul Bourgeois. At Napoleonville, a few chimneys were damaged also and a few windows were broken and some furniture moved. These facts suggest a MM VI rating for Gonzales and Napoleonville. At Allemends - 37 miles southeast of Donaldsonville - some pictures fell indicating a MM VI. However, the earthquake itself was reported felt by only a few people. The town of Morgan City, Donaldsonville, Franklin, and White Castel felt the earthquake at MM V level.

2.5.2.1.4 1931, August 16 - Valentine, Texas Earthquake

The Intensity VIII (MM) Valentine event, affecting 450,000 square miles is Texas’ largest historic earthquake. Damage was most severe at Valentine, as the epicenter was nearby at Mount Livermove.

Isoseismal mapping (Figure 2.5.2-5) indicates that damage could have been more widespread in a populated area. Good documentation has been provided by Sellards [30], and by Byerly [31, 32]. Byerly has computed the Richer magnitude of this event as 6.4. The event was felt in Waco, as well as most northern and central Texas cities. For instance, a Waco newspaper reported this earthquake without reference to its origin, giving rise to erroneous suggestion of a Waco earthquake. The epicenter of the earthquake was approximately 380 miles from the CPNPP site

and produced a Rossi-Forel Intensity II-III (Modified Mercalli Intensity II-III) at the site. This event is not associated with structures near the site.

2.5.2.1.5 1932, April 9 - Wortham-Mexia, Texas Earthquake

Regarding the Mexia earthquake, Frank Neumann of the USCGS states [86]:

> "April 9; 4:15. Mexia and Wortham, Texas, MM V. Loose bricks thrown down. Plaster cracked. Damage slight. Also felt at Cooledge, Currie, Groesbeck, Hillsboro, Teague, and Richland. A detailed report by E.H. Sellards was published in University of Texas Bulletin issued in February, 1933."

The report appearing in the Bulletin of the Seismological Society of America (BSSA) stated [87]:

> "Richland, Texas. April 9, 1932. --Windows were rattled and houses shaken by several slight earth tremors felt in Richland, Currie, Wortham, College Station, Mexia, Groesbeck, Teague, and other small towns in the vicinity shortly after 4 A.M. on April 9th. Damage was limited to fallen chimneys."

The report in the Houston Chronicle for Sunday, April 10, 1932 read:

> "Light Earth Tremor Felt Around Mexia"---"More than Seven towns in that Vicinity Feel Shock; Little Damage is Caused by Disturbance, Associated Press. Corsicana, April 9.---Earth tremors were felt shortly after 4 A.M. today at Richland, Coolidge, Mexia, Groesbeck, Teague, and other towns in that vicinity. People were awakened by the rattling of windows and the shaking of buildings. Little damage was reported. The disturbance seemed to center at a point between Wortham and Mexia, where the tremors were most pronounced. The tremors decreased in intensity away from this point. Apparently the disturbance affected an area about 25 miles in diameter. A check was made to determine whether blasting operations could have been responsible, but nothing of this nature was found, so it was decided the tremors were caused by some subsurface disturbance. The affected area was situated along the Balcones fault, well known to oil men. Renewed faulting was believed to have been a possible cause. A report from Mexia said that the tremors were felt at 4:13 A.M. Wortham reported it as occurring at 4:17 A.M. The shocks were but a few seconds duration. Several brick chimneys toppled at Wortham and Mexia, but otherwise damage was negligible."

By far the most detailed account of this earthquake is given by Sellards based on observations he made in the area from May 2-5, 1932. No seismograph recorded this earthquake. Sellards states that the seismographs at Denton, 110 miles northwest of Mexia, and at Austin, 120 miles southwest of Mexia, failed to register the earthquake [33].

Sellards found that most of the damage caused by the earthquake occurred at Wortham. The effect of the earthquake at Wortham "was only to shake bricks from a few chimneys and to enlarge or develop cracks, possibly already present as incipent breaks, in one brick veneer building." He further states that "the most pronounced of these cracks is at the northeast side of the house and runs in a zigzag course from the roof to a window and from the bottom of the window to the concrete baseboard and does not pass through the brick. Some cracks in this building had formed previous to the earthquake."

At the home of a Mrs. Turner, in the southwestern part of town, Sellards found that “four top layers of brick were loosened from the chimney. Twenty four bricks fell to the ground, and the other of these four layers were more or less displaced.” A few bricks fell from other chimneys in the southern and southwestern parts of Wortham. Sellards says that “the bricks in the chimneys affected were probably not firmly held by the mortar, as indicated by the fact that the bricks separated in falling.”

Sellards states that almost everyone in Wortham was awakened and more or less alarmed. “Many ran out of their houses or made examinations to determine the cause of the disturbance.” He ranked the intensity as a V on the Rossi-Forel scale.

Sellards states that outside Wortham the effects were less perceptible. He says that “at Mexia only a few people were awakened. Many were more or less alarmed, but no damage of any kind resulted. At this place the intensity was not above IV (RF).” A Mr. R.A. Liddle gave Sellards a detailed account of his recollecting the event. Mr. Liddle stated that the tremor came from a southeasterly direction; that no sound was heard other than the creaking of the building; and that dishes and stoves rattles. Mr. Liddle further states that “the second movement was several seconds after the first, and was barely noticeable.”

Sellards states that in all directions from Mexia and Wortham, the tremors died out very rapidly. “At Richland, 10 miles northeast of Wortham, the earthquake was felt by only a few persons who were already awake. At Teague, 12 miles east, and at Groesbeck, 11 miles south of Mexia, a slight shock was felt by only a few persons. To the west as far as Prairie Hill, 18 miles, the shock was felt by several persons some whom were awakened.” Finally, Sellards found that the maximum distances at which the shock was at all perceptible to persons awake were Corsicana, 21 miles north of Wortham, Thornton, 19 miles south of Mexia, and Watts, 23 miles west of Mexia. At Fairfield, 19 miles east of Mexia, the shock was not perceptible and at Streetman, 10 miles northeast of Wortham, the shock was “scarcely perceptible.” Sellards’ outline of the sensible area is shown in Figure 2.5.2-6.

Sellards located the earthquake on the Mexia-Wortham faults west of Mexia. The quake was located here because at Tehuacana the shock was fairly strong and because the tremor was sensible for a greater distance west of Mexia than east. The main inconsistency with this location is that Wortham, where the shock was the strongest, is not central to the area in which the earthquake was felt. Possibly if faulting occurred from south to north along fault, the greater intensity at Wortham may be explained by a focusing effect. The USCGS [83] locates the epicenter about eight kilometers east and slightly north of Mexia which is indicated in Figure 2.5.2-6. The only other epicenter location that has been estimated was by Docekal [69], who puts the epicenter 16-17 km almost due south of Mexia, as shown in Figure 2.5.2-6. This location is probably too far south of Wortham and too close to Groesbeck which did not experience any damage from the quake. The USCGS location would more or less agree with Mr. Liddle’s feeling that the shock originated southeast of Mexia [83].

The most likely explanation for the damage experienced at Wortham and the small perceptiple area is that the event occurred at shallow depth. Local geologic conditions may have added to the problem by locally amplyifying or at least failing to attenuate the ground motion.

The most recent intensity assigned to this earthquake is MM V-VI by Coffman and Von Hake [70]. The felt area given is 1,000 square miles in agreement with the area contained within Sellards’ “limit of felt area” of radius 17 miles. A higher intensity of MM VII is given to this earthquake by

Docekal [69]. It apprears that the Docekal value is based on chimney damage alone (see previous description of chimney damage). The felt area given by Docekal is "2,000 sq. mi." [69]. According to Brazee's [88] (Figure 2.5.2-7), and Nuttli and Zollweg's [117] recent work on felt areas for earthquakes in the eastern and central U.S., both of these assigned intensities are too large for the Wortham-Mexia Earthquake. Even a MM V maximum intensity for this earthquake yields a felt area five times that given by Sellards.

The possibility exists that this event may be related to petroleum withdrawal in the area. The first major Texas oil discovery occurred in June, 1894, when the city of Corsicana was drilling a water well. The Mexia Field was discovered in 1920, and the Wortham Field in 1924- 25. The Mexia field is shown in Figure 2.5.2-6. The Mexia Field covers an area of about 3800 acres. Figure 2.5.2-7 shows the annual amounts of crude oil taken from the Mexia field from 1920 up to and including 1932 (data for the years 1927-1929 could not be obtained). For each barrel of crude oil taken out, there are roughly two and one- half barrels of saltwater removed [89].

Two years earlier, Sellards [90] had studied subsidence in the Goose Creek Oil Field in Harris County, Texas. Sellards writes that, unlike the Goose Creek Field where "the geological section includes only relatively incoherent strata, under conditions as at Mexia where the section includes resistant strata, as the limestone of the Midway and Austin formations, subsidence, if such occurs might result in a jar locally producing a tremor of considerable force." Sellards then calculates the total volume of fluid withdrawn from the Mexia and Wortham Fields. This amounted to some four billion cubic feet.

Sellards concludes by saying: "Whether this tremor therefore proves continued activity in the Mexia-Wortham line of faulting or records merely local subsidence in these oil fields incident to the removal of oil is at present undetermined."

In addition to the Corsicana and Mexia-Wortham Fields, there are a number of other oil fields along the Mexia-Talco Fault System. Some of these fields still producing are listed below:

Cumulative Oil Withdrawn
From Discovery to 1/73
by Counties

Discovery Date	Field	County	Area (Acres)	(106 BBLS)
1894	Corsicana	Navarro	4000	192
	Darst Creek	Guadalupe	1900	157
1925	Lytton Springs	Caldwell	2000	
1928	Salt Flat	Caldwell	7000	227
1936	Talco	Titus & Franklin	9500	298

The combined total area of these fields is about 25,000 acres. The counties in which the above and smaller Mexia-Talco Fault Zone fields are located have produced about 875 million barrels of oil to date compared with the 110 million barrels withdrawn from the Mexia-Wortham Fields as of

January 1932, as calculated by Sellards [33]. If the Wortham-Mexia event of 1932 was caused by petroleum withdrawal, it was certainly anomalous in light of the far greater volumes withdrawn from other fields along the fault zone (underlain by essentially similar geological conditions) without any recorded or reported seismic activity.

Sellards [33] states that as of January 1, 1932, 704 x 106 cubic feet of gas had been taken out of the Mexia and Wortham Fields. While the report in the Houston Chronicle [19] states that no blasting operations were in progress at the time of the earthquake, the possibility of an underground gas explosion cannot be ruled out as a possible cause of the disturbance. If faulting were the cause, according to Brazee [88], an area within a radius of some 35 miles should have felt the earthquake at intensity V level if the maximum intensity of the Mexia quake is assigned an MM V rating.

2.5.2.1.6 1952, April 9 - El Reno, Oklahoma Earthquake

The El Reno, Oklahoma event in one of the largest historic earthquakes in Oklahoma. Cloud and Murphy [27] indicate that the event was felt over Oklahoma (except for the panhandle), eastern Kansas, central and northern Texas, western Iowa, Missouri, Arkansas and the southern tip of Nebraska. Slippage along the Nemaha fault about five miles southwest of Oklahoma City is credited by Cloud and Murphy as the source of the event and the felt data conforms to the known trace of the fault. Figure 2.5.2-8 outlines the areas in which the various intensity levels were observed. Maximum intensity was VII although damage was not extensive. Portions of chimneys fell in El Reno and Ponca City and bricks loosened from a building wall and tile facing of commercial buildings bulged at Oklahoma City.

Intensity I-III was reported from Dallas and Fort Worth, Texas for this event. Aftershocks were observed on April 11, 16; July 16, and August 14.

2.5.2.1.7 1959, June 17 - Lawton, Oklahoma Earthquake

Eppley and Cloud [93] report that this shock was felt over an area of about 12,000 square miles in Oklahoma and Texas. Maximum intensity for this event was VI and slight damage consisting of a few reports of cracked plaster and minor pavement cracking was reported.

Intensity levels of I to IV were reported from Dallas and Wichita Falls. The configuration of isoseismals for this event (Fig. 2.5.2-9) exhibit a marked attenuation transverse to geologic structure to the south, in the direction of the site.

2.5.2.2 Geologic Structure and Tectonic Activity

In the following sections all tectonic provinces within 200 miles of the site are identified and described. These provinces are delineated on the basis of 1) basement type; 2) relative isostatic stability of each type; and 3) specific history of stress application within the same crust and tectonic fabric. These major tectonic provinces are further subdivided on the basis of magnitude and mode of crustal deformation, and timing of stress application. Both the timing and magnitude of crustal activity is recorded in the stratigraphic thicknesses and facies distribution throughout the region.

The term tectonic province as used in this study is a region of the North American continent characterized by a relative consistency of the geologic structural features contained therein.

Principal geologic structures and faulting are described with regard to development of the tectonic provinces and relation to existing seismicity.

2.5.2.2.1 Regional Tectonic Provinces

Earthquakes are generated by the release of strain which has accumulated due to regional or local stresses. Sbar and Sykes [95] state that: "In eastern North America intercratonic earthquakes appear to occur in areas of high stress along unhealed fault zones of late Paleozoic or younger age," thus emphasizing the need for a detailed geologic investigation. They describe two types of contemporary stress that are possible along these faults. Remanant stress is defined as "that stress remaining in the rock after the stress applied at some earlier time has been removed." Tectonic stress, on the other hand, can be caused by (1) glacial unloading such as in eastern North American (Woolard [96] (2) sinking of oceanic crust (Sclater, et al. [97], (3) lithostatic loading, such as the Gulf of Mexico (Hubbert and Willis [98], Voight [99]; (4) differences in thickness and density distribution in the continental and oceanic crust at the continental margin (Bott and Dean, [100]); and (5) convective flow in the upper mantle (Voight [99], Morgan [101], Sbar and Sykes [95], among others).

Given these origins of stress and possible location of earthquakes on unhealed faults, it is not possible to make meaningful delineations of tectonic provinces without a detailed study of the geologic history of a given region. In addition, the state of the art geologic concepts learned from detailed studies in other areas of similar geologic fabric and history must be considered. Seven tectonic provinces are delineated within two hundred miles of the Comanche Peak Nuclear Power Plant as indicated on Figure 2.5.2-2. Clockwise from the site these are: 1) the West Central Texas Province; 2) the Wichita province; 3) the Seminole Arch-Nemaha Uplift Province; 4) the Ouachita Province 5) the Balcones-Mexia-Talco Province; 6) the Mesozoic Shelf Province; and 7) the Gulf Coast Province.

These provinces can be grouped according to the history and origin of the underlying crust: (1) Precambrian continental crust which can be undeformed or deformed; (2) deformed Paleozoic oceanic crust; and (3) downwarped Precambrian or Paleozoic oceanic crust. The West Central Texas and Seminole Arch-Nemaha Uplift Provinces are underlain by relatively undeformed Precambrian crust. The Wichita province is underlain by Precambrian crust that has been deformed by the Wichita Orogeny. The Wichita Orogeny occurred during Upper Mississippian through about Mid-Pennsylvanian time and resulted in a series of generally northwest to southeast trending structural features reflecting southwesterly to northeasterly compressional forces.

This major group of Provinces involving Precambrian crust was partially overridden during the Ouachita Orogeny. This orogeny, extending to slightly more recent time than the Wichita and involving compressional forces from the south and southeast, consolidated Paleozoic oceanic crust and its overlying sediments forming the crust that now underlies the Mesozoic Shelf Province [56].

The Balcones-Mexia-Talco Province represents the response to the collapse of the Ouachita Belt perhaps at the Precambrian continental margin [47]. To the south of the relatively stable Mesozoic Shelf Province is the Gulf coast Province. The crust underlying this province has undergone continuous subsidence since its origin [57, 58], receiving more than 60,000 feet of sediments.

The classification of tectonic provinces presented above represents regional interpretation based on gross structural geologic characteristics, crustal structure and geologic history. Each of the major provinces can be subdivided into tectonic subprovinces based on an understanding of more definitive structural criteria and the interaction of structural elements throughout geologic time. Although genetically related to the major province, each subprovince can be defined by its unique structural characteristics.

The provinces and subprovinces shown on Figure 2.5.2-2 are considered sufficiently detailed to allow development of the Safe Shutdown Earthquake for the CPNPP site and are identified along with their principal tectonic components in the following section.

1. West Central Texas Tectonic Province

   The West Central Texas Province is bounded to the north by the Wichita Province and to the southeast by the Ouachita Province.

   The backbone of the province (the Precambrian Crust) crops out in the Llano Uplift subprovince. The other subprovinces are delineated using Upper Paleozoic geography. The paleography includes basins: 1) Delaware; 2) Val Verde; and 3) Midland, making up the basin subprovince; and the Central Basin Platform making up the other subprovince. The area not included in these subprovinces is called the Central Texas Shelf subprovince [59].

2. Wichita Tectonic Province

   The Wichita Tectonic Province lies to the north of the West Central Texas Province and is differentiated from it by structures formed during the Wichita Orogeny. Major structures, folds, and high angle reverse faults strike predominantly northwest-southeast throughout the extent of this province. This province is bounded to the northeast by the Seminole Arch-Nemaha Uplift Province and to the east by the Ouachita Province.

   The Wichita Orogeny formed four subprovinces which include two uplifts and two depressions. The southern boundary is the Matador-Red River-Muenster Uplift subprovince. This is separated from the Amarillo- Wichita-Arbuckle Uplift subprovince by the Palo Duro Basin subprovince. The Anadarko Basin subprovince forms the northern boundary of the Wichita Province.

3. Seminole Arch-Uplift Tectonic Province

   The Seminole Arch-Nemaha Uplift Tectonic Province is a relatively stable area bounded on the south and west by the Wichita Province and to the southeast by the Ouachita Province. This province remained stable while over 28,000 feet of sediments were being deposited in the Anadarko Basin (a subprovince of the Wichita Tectonic Province) and approximately 17,000 feet of sediments were being deposited in the Arkoma Basin to the east the northernmost subprovince of the Ouachita Province. Preconsolidation deformation near Bartlesville, Oklahoma suggests significant past earthquake activity in this area [118].

4. Ouachita Tectonic Province

The Ouachita Tectonic Province represents he inland extent of the complex zone of deformation formed during the late Paleozoic Ouachita Orogeny. This orogenic pulse, which featured compressional forces from the south and southeast, consolidated Paleozoic oceanic crust and it overlying sediments and produced overthrusting along the contact with the Precambrian continental landmass. The Province is bounded on the west by the stable West Central Texas Tectonic Province, on the northwest by the Wichita and Seminole-Nemaha Uplift Tectonic Provinces, and in a gulfward direction by the peripheral fault systems of the Balcones-Mexia-Talco Tectonic Province. It can be differentiated into three subdivisions based upon the relationship of the tectonic belt to underlying structural trends and/or to subsequent structural behavior.

4.1 Exposed Ouachitas

This subprovince contains uplifted and exposed deformed Paleozoic sediments that overrode the Precambrian continental crust from the south. Its northern portion, the Arkoma Basin, contains east-west trending gently folds and faults. The Ouachita Mountains, in the southern portion, feature tight, closely spaced folds and numerous east-west trending high-angle reverse faults and thrust sheets.

4.2 Wichita Ouachita

This subprovince is a transitional zone, where the predominant structural trends change from east-west to northeast-southwest. It also represents the region where the Ouachita Orogenic Belt overrode the southeastward-plunging structures of the Arbuckle Uplift and Muenster Arch portions of the Wichita Tectonic Province which were formed during the earlier Wichita Orogeny.

4.3 Buried Ouachita

This subprovince represents the portion of the Ouachita Tectonic Belt that was placed on the Precambrian continental crust of central Texas then subsequently overlapped and buried by extensive Cretaceous sediments.

5. Balcones-Mexia-Talco Tectonic Province

The Balcones-Mexia-Talco tectonic province and eastern counterpart, which includes the South Arkansas and Pickens-Quitman-Gilbertown Fault Systems, represent a complex system of normal faults that developed at the periphery of the Gulf Coastal Plain in response to the collapse of the Ouachita Orogene. Tensional forces developed during a relaxation that followed the compressional phase of the orogenic cycle, causing the formation of classic post-orogenic block faulting. The inner boundary of this province is defined by the innermost faults of the Balcones system; the gulfward boundary, with the Mesozoic Shelf Tectonic Province, is defined by the outermost faults of the Luling and Mexia-Talco fault systems. Although the deformed Paleozoics of the Ouachita Orogene undoubtedly extend gulfward of the limits of the Ouachita Tectonic Province and probably served as the foundation upon which the Mesozoic Shelf Tectonic Province was developed, it is considered that subsequent to the compressional phase of the Ouachita

Orogeny, tectonic activity was largely confined to the regional zone of weakness defined by he peripheral fault systems. This long, linear province then serves as a logical buffer zone or tectonic boundary between the older Ouachita Tectonic Province and the younger Mesozoic Shelf Tectonic Province.

6. Mesozoic Shelf Tectonic Province

The Mesozoic Shelf Tectonic Province is defined as a geologically stable shelf area that developed on the relatively thick subcontinental crust of Paleozoic sediments deformed during the Ouachita Orogeny. Its inner boundary is defined by the peripheral fault systems that were formed over the Ouachita Tectonic Belt and which are herein called the Balcones-Mexia-Talco Tectonic Province. Movement along these basement-related faults commenced in the late Paleozoic or early Mesozoic [102] and continued intermittently until at least early Tertiary time [15, 63, 103], although some faults of this province seem to displace formations as young as Pliocene [15].

The Mesozoic Shelf Tectonic Province is bounded in a gulfward direction by the Stuart City Reef which marked the lower Cretaceous shelf edge and is located above the zone of crustal transition from relatively thick subcontinental crust in a landward direction to thin oceanic crust in a gulfward direction [104, 105].

The above province and boundary descriptions apply for the overall Mesozoic Shelf Tectonic province. The province, however, contains several major subdivisions.

6.1 East Texas Embayment

The East Texas Embayment is at least as old as the Jurassic and was well developed by the beginning of lower Cretaceous time. The total thickness of Jurassic sediments is unknown, but the maximum thickness of Cretaceous and lower Teritiary sediments (predominantly marine) probably exceeds 15,000 feet [106]. The Houston Embayment is the downdip counterpart of the East Texas Embayment, and the Tyler, or Mineola Basin, is the deepest part.

The axis of the embayment was originally essentially north-south, but movement of the Sabine Uplift during upper Cretaceous time deflected the axis so that the northernmost portion now trends northeasterly [102].

The East Texas Basin contains a series of shallow piercement salt domes which have developed from the Jurassic parent salt unit in response to loading by the thick sedimentary over burden.

6.2 Sabine Uplift

The Sabine Uplift is a broad domal feature that persisted as a stable structural element throughout the Cenozoic [107] as is clearly indicated by the sediments that thin across it. A series of short, discontinuous faults has developed across the uplift and along its flanks. The Sabine Arch is a southward extension of the uplift that persisted throughout the Cenozoic as a stable positive structural element.

6.3 Mount Enterprise

The extent of the Mt. Enterprise subprovince is defined by faults of the Mt. Enterprise System. As defined by Murray [102], these structures bear no presently discernible relationship to other known systems of faulting. Faults of this region typically form graben structures with dips ranging between 35° and 60°. Activity may have commenced as early as Comanchean (lower Cretaceous) time but movements reached a maximum during Gulfian (upper Cretaceous) time and continued at least into the Claibornian (middle Eocene).

The Stuart City Reef marked the Comanchean shelf edge, separating the lagoonal depositional environments of the Mesozoic Shelf from the deep water environment of the ancestral Gulf of Mexico.

In Texas, this reef trend is now buried under more than 10,000 feet of younger sediments but its younger equivalent in Mexico (El Abra) is exposed in outcrop.

7. Gulf Coast Tectonic Province

The Gulf Coast Tectonic Province is divided into an east and west division by the Sabine Arch similar to the Mesozoic Shelf Province. This division separates the two major depocenters of the Gulf Coast Tertiary geosyncline. During the Eocene and Oligocene, the area of maximum deposition (over 50,000 feet) was central and southern Texas but, during the Miocene and Pliocene-Pleistocene, the depocenter (over 40,000 feet) had shifted to a position off southern Louisiana [61].

2.5.2.2.2 Geologic Structures and Faults

In this section the locations of geologic structures and descriptions of the significant faulting in each tectonic province are presented. The significant geologic structures and faults are shown in relation to the tectonic provinces on Figure 2.5.2-2.

1. West Central Texas Tectonic Province

The West Central Texas province is part of the central stable region of the United States founded upon Precambrian crystalline rock and mantled by a thin veneer of sedimentary rock. The crystalline basement is comprised of both igneous and metamorphic rocks similar to rocks of the Canadian Shield.

The central stable region has undergone vertical movements resulting in the formation of broad basins and arches. The arches, basins and other structures of this region formed principally during the Paleozoic era. These structures are rippled and checked by numerous folds, faults and unconformities which constitute important structures for oil and gas accumulation.

The Concho arch, which rose in late Devonian time, is the principal structure of the West Central Texas Basin [108]. The arch consists of a broad gentle uplift in central Texas that extends from the present Llano Uplift northwestward at least 150 miles and may have connected with uplifts in northeastern New Mexico and southern Colorado. West of the arch is the Reagan Range, a small sharp uplift. Immediately west of the Reagan Range

is the Pecos Range which extends northward into Southeastern New Mexico. During Permian time the Pecos Range was known as the central basin platform. Farther to the west is the Diablo Range which parallels the Rio Grande and extends from the west Texas Davis Mountains northwestward to New Mexico.

The Llano Uplift and its northeastward extension, the Bend Arch came into existence in Cretaceous time but had their beginnings toward the end of the Pennsylvanian.

Major basins developed between uplifts at different times. The Fort Worth (Strawn) and Kerr basins are chiefly Pennsylvanian depressions on either side of the Concho arch. The basins and platforms of west Texas formed in Permian time.

Faults of the Llano Uplift are known from surface mapping [111]. Well and geophysical data have extended the known length of these faults more than 100 miles to the north-northeast into the Strawn basin. The faults are probably high-angle and normal and have blocked out narrow grabens and horsts. These high blocks from east to west are the Richland Springs, Pototac, San Saba and Lampasas arches. Geophysical data from the Fort Worth basin has shown that some of these faults have displaced the Smithwick (early Pennsylvanian) formation at 1100 feet. However, middle Strawn beds only slightly younger in age are only slightly disturbed along a major fault near Regency in the Colorado River area [108].

No evidence of this faulting is known in younger Pennsylvanian beds. Therefore the faulting in the Llano Uplift and the Strawn Basin occurred in early Pennsylvanian time or earlier [2,108].

2. Wichita Tectonic Province

Geologic structures of the Wichita Tectonic Province are the Wichita Mountains, the Amarillo Uplift, the Criner Hills, the Red River Uplift, the Arbuckle Mountains, and the Anadarko and Ardmore Basins (Figure 2.5.2-2).

The Amarillo Uplift, the Wichita Mountains and Criner Hills comprise a single tectonic unit extending some 330 miles from Southwestern Oklahoma into the northwestern Panhandle of Texas. Precambrian granites form the cores of the Wichita mountains. The Amarillo Uplift is a series of buried hills without surface expression also composed of granite and crystalline rocks overlain by Permian and Pennsylvanian strata and bounded by an echelon faults. The Criner Hills are a complexly-faulted horst exposed at the surface and considered a southeasterly continuation of the Wichitas.

The Red River uplift is comprised of narrow east-west buried granite hills which extend from the New Mexico line across the Llano Estacado to Wichita Falls and then to the southeast. Well-expressed faults and folds trend obliquely across the uplift in a northwest direction producing an echelon offsets of the buried granite ridges. The western portion of the Red River Uplift is known as the Matador Arch, the east central part as the Electra Range, and the eastern end as the Muenster Range.

The Arbuckle Mountains are the surface expression of a complex anticline between Davis and Ardmore. The core of the anticline consists of two prominent peaks of Precambrian rocks with folded sequences of Precambrian to late Pennsylvanian rocks exposed in

range. Major features of the series of northwest-southeast-trending faults and folds comprising the Arbuckles from north to south include the Hunton Arch, the Mill Creek syncline, the Tishomingo anticline, the Wichita syncline, and the Arbuckle anticline.

The Ardmore basin is a west-northwestward-trending trough between the Criner Hills on the south and the Arbuckle Mountains on the north and contains over 30,000 feet of Paleozoic sediments.

North of the Wichita Mountains lies the Anadarko basin which occupies much of western Oklahoma. The axis trends west-northwest and approximately parallels the Wichita-Amarillo Ranges.

The early Paleozoic Wichita geosyncline was compressed into northwest fault blocks and folds of the Wichita and Red River uplifts in early Pennsylvanian time; and then again in late Pennsylvanian time the Arbuckle Mountains were formed by north-south compression. This complex of related chains is known as the Wichita system [108].

3. Seminole Arch-Nemaha Uplift Tectonic Province

The Nemaha Range, a sharp uplift, trends south-southwest from Omaha, Nebraska into northern Oklahoma. The range is buried beneath a considerable thickness of Paleozoic strata. Uplift and dissection were sufficient to expose Precambrian crystalline rocks before burial. The east flank is bounded by the Nemaha which extends into the Wichita trend to the south [83].

The Seminole Arch extends northward from the Arbuckle Mountains. Both the Seminole and Nemaha structures appear to be block-faulted. All of these geologic structures are located over 170 miles from the site.

4. Ouachita Tectonic Province

Four independent thrust sheets form the principal tectonic structures of the Ouachita Tectonic Province. From northwest to southeast these are the Choctau, the Pine Mountain, the Ti Valley fault and the Windingstair faults. Each of these sheets has been thrust from south to north and has been broken by numerous smaller high-angle reverse faults that probably join the main thrusts at depth. Larger cross faults are occasionally present with numerous minor cross faults. The major thrusts of the Ouachita system have been identified in eastern Oklahoma but appear to die out to the east in the shale sequences. None of these thrust faults are presently known to be active. A zone of open folds lies to the north and comprises the Arkoma Valley basin.

5. Balcones-Mexia-Talco Province

The Balcones-Mexia-Talco faults are a complex assembly of faults that follow approximately the border of the Tertiary and Cretaceous formations of the Gulf Coastal Plain and are probably related to collapse of the continental margin on the seaward side of Paleozoic orogenic belts [47, 113].

It is believed that the fault systems, generally categorized as the Balcones, Luling-Mexia-Talco, and Charlotte-Fashing fault zones, have basement control or deep

tectonic involvement, and that thege fault systems are formed over the original zone of weakness that allowed the Ouachita Geosyncline to form along the edge of the Texas Craton [112].

Wells drilled in the general area of the Balcones fault system encountered beneath the Cretaceous a sequence of steeply-dipping clastic sedimentary rocks showing varying degrees of weak metamorphism [3]. Near the beginning of the Miocene period (about 22.5 million years ago) the Coastal Plain strata faulted and slumped towards the Gulf at an increased rate of speed [15]. This was due to a readjustment of the earth's crust caused by sinking of the Gulf Coast region under the heavy load of Cretaceous and Tertiary sediments. The Balcones fault acted as the hinge over which the sediments attempted to stretch [63]. The movement on the Luling-Mexia-Talco fault system was likely due to readjustment incidental to the Balcones faulting and the consequent dip towards the Balcones zone.

The Balcones fault zone forms a great arc, convex gulfward. Its strike is easterly in Kinney, Uvalde and Medina Counties and changes to northeasterly and then north-northeasterly across Bexar, Comal, Hays, Travis, Williamson, Bell, and McLennan Counties.

Faults in the zone are all normal and trend mostly down to the coast, with antihetic faults that form grabens. Distinct faults within the zone are partially an echelon. The average dip of the fault is 45 degrees which generally decreases with depth [15, 47]. It is believed that these normal faults penetrate the basement, beneath Cretaceous and Tertiary sediments. A typical cross section through the Balcones Fault Zone is shown on Figure 2.5.2-11.

Displacements of up to 1,500 to 1,700 feet occur across the Balcones fault zone. The latter figures are for Bexar County in which maximum displacement has been reported. Northeast and southwest of Bexar County the displacement diminshes in magnitude. Individual faults may have any amount of displacement up to 700 feet. Topographic relief along the fault also varies from extensive to none. A prominent escarpment exists throughout most of the area where more resistant Lower Cretaceous strata have been uplifted [47].

The Luling-Mexia-Talco Fault Zone probably represents complimentary (antithetic) up-and-down-to-the-coast movements that developed in response to the down-to-the-coast movement along the Balcones Fault Zone [64]. A typical cross-section through the fault zone is shown in Figure 2.5.2-12. The Balcones and Luling-Mexia-Talco fault zones, although related to the action of the Gulf Coast Geosyncline, are not considered growth faults as are the younger more coastward faults. Although they exhibit some of the same characteristics as growth faults (i.e., decreasing dip with depth) they are believed to have basement control as opposed to the more shallow and younger faults in the thicker sediments of the Gulf Coast Geosyncline [47].

Both the Balcones and the Luling-Mexia-Talco fault systems pass within 200 miles of the site. The Balcones system, the nearest, passes within 50 miles of the site and is situated just east of the Ouachita Tectonic front. The Luling-Mexia-Talco Fault system passes within 80 miles of the site to the east and generally is parallel to the trend of the Balcones system; both fault systems are shown on Figure 2.5.2-13.

The possibility of the Balcones and the Luling-Mexia-Talco fault systems being active according to 10CFR100, Appendix A, has been carefully considered. Details in the literature, field observations by prominent earth scientists, the opinions of other experts and our own assessment of field conditions have all lent appropriate weight in making a judgement. Insufficient evidence exists to warrant classification of these fault systems as active along any portion of their known limits.

The 300-mile-lone Balcones fault zone passes closest to the site in Hill County at which location it is 50 miles southeast of the site.

An examination both of areal photographs and field conditions was conducted in order to evaluate the possibility of activity along the nearest portion of the fault zone. These efforts revealed no sound evidence indicating any degree of activity. In many cases, faults within the zone have brought earth materials of contrasting physical properties into juxtaposition. Problems of civil structures stem from this cause or others, rather than from displacement along the failure (fault) plane.

The investigation of possible activity included a thorough field inspection of both the closest approach of the fault system to the site and the closest municipalities to these points along the fault. The purpose of the latter investigation was to obtain evidence that would not be apparent in an undeveloped area; evidence such as distressed buildings and streets, utility line maintenance records, etc. This field investigation also included interviews with individuals who had knowledge of the fault system, including academic personnel (retired and active), petroleum companies, government and private consulting geologists. In addition, Soil Conservation Service personnel were questioned about any anomalous field observations they might have observed over the years. Public works employees in Waco, Hillsboro and Austin were interviewed, including water, sewer, and street maintenance personnel. County and state highway maintenance personnel were also interviewed. The list of personnel contacted is provided in the references. This investigation effort failed to reveal any evidence of fault activity. In addition to the intensive investigation of the fault in the site region an investigation was made to obtain evidence of activity along the entire length of the fault. Again, no evidence of activity was found.

Activity along the Balcones Fault Zone may have started as early as Jurassic time (195 million years ago) and persisted through the Tertiary. Nowhere is there evidence that terraces of Pleistocene age (1.85 million years) or younger have been displaced through faulting.

Accounts do appear in the geologic literature that appear to indicate historic movements in the ground surface, across highways, archaeological digs, and pipelines.

Bryan [36 and 37] indicated that sewer and water mains in McLennan County were severed where they crossed faults in the Balcones system. Investigation of this reported occurrence conducted in Hill, McLennan and Travis Counties and interviews with a geologist familiar with other portions of the Balcones fault system failed to disclose evidence for movements across highways or pipelines along faults within the system.

Weeks [15] cities “breastworks” near Lexington in northern Lee County as possible evidence for relatively recent movements along a portion of the Luling-Mexia-Talco Fault

Zone. He describes these “breastworks” by saying that the upthrown side of the fault stands a few feet higher at the surface than the downthrown side. However, in retrospect, Weeks says that the features he observed by chance in the field in 1945 could very likely be attributed to sources other than fault breakage, such as differential settlement or differential weathering along the fault zone (Weeks, personal communications).

Wiggins [39], in describing the geology of the Ham-Gosset Oil Field, noted disturbance of roads in the Luling-Mexia-Talco fault zone, and suggested that this represented surface fault rupture. During recent conversations with the author (Wiggins, personal communication) he indicated that several times since publication of the paper he has endeavored to confirm his initial hypothesis, but has not been able to do so.

Bell and Brill [38] reported a persistent crack in sandy soil in eastern Lavaca County over the Mirando-Provident City fault zone, and Sellards [33] reported a crack near Wortham; however, Lavaca County is over 200 miles from the site and it was not possible to establish the validity of the observations as clear proof of active faulting; or of oil field subsidence.

Seismic activity of any significance is not normally associated with faults in the region.

An earthquake had been reported in the literature [36] as having occurred along the Balcones fault in or near the city of Waco on August 16, 1931. However, neither of the Waco newspapers of the time (Waco News Tribune and Waco Times Herald, August 17, 1931) reported any local tremors, although the August 16, 1931 earthquake of Valentine, Texas received abundant press coverage in Waco. The Valentine event is the largest to have been recorded in the state, and it was felt in Waco. See the dicussion of important earthquakes in Section 2.5.2.1.

Slow, continuous, viscous movement of soil or rock masses without seismic disburbance is commonly referred to as “creep” or “tectonic creep” if it can be demonstrated that releases of tectonic stress have been the cause rather than other stresses associated with activities of man.

In the vicinity of the city of Houston it is known that creep is occurring now along normal down-to-the-coast faults. The question therefore arises as to whether this coastward activity can be related to major tectonic structures far removed from the coast as are the Balcones and Luling-Mexia-Talco fault zones [40, 41, and 42].

As stated previously, creep is probably caused by shearing and plastic deformation along the Louann Salt. From Figure 2.5.2-10 it is evident that the geographic distribution of the Louann Salt is such that it plays no part in the tectonics of the Balcones and Luling-Mexia-Talco fault systems. For these structures, rather, it is likely that there is basement control.

6. Mesozoic Shelf Tectonic Province

The Mount Enterprise Fault System refers to a restricted series of faults in the southern part of the East Texas Embayment in Anderson, Cherokee, Rusk and Panola Counties. This includes the Mt. Enterprise, Holly Grove, Jacksonville, Elkhart, Medford, Elkins and other un-named faults lying along this trend in the counties mentioned.

The Mount Enterprise Fault system lies at the southern rim of the East Texas Basin on the western edge of the Sabine Uplift. The system represents a series of narrow graben structures that developed in repsonse to tensional forces caused by the arching of sediments across a buried spur of the Sabine Uplift and occupies the southern limit of the East Texas Embayment. Aeromagnetic data reveals a basement ridge beneath the Mt. Enterprise Fault System.

The time frame of the faulting is consistant, in that post-Claibornian (Eocene) faulting took place after the rapid downwarping of Claibornian time during which the sediments reached maximum thickness. The Mt. Enterprise faults therefore are actually related to downwarping of the Tyler Basin and independent of other regional fault systems.

The closest approach of the Mt. Enterprise Fault system to the site is 125 miles.

7. Gulf Coast Tectonic Province

Coastward of the Balcones-Mexia-Talco system of faults lies a series of major down-to-the-coast faults with compensating up-to-the-coast faults that trend roughly parallel to the Gulf of Mexico. Included in this system are the Wilcox (Mirando-Provident City), Vicksburg (San Fordyce-Vanderbilt), McAllen and Williaman fault zones of Texas; the Bancroft Fault Zone of Texas and Louisiana; and the Mamou, Tempetate- Baton Rouge, Lake Arthur and Grand Chenier fault zones of Louisiana.

In contrast to the older fault systems, the younger faults in the Gulf Coast Tectonic province are not believed to have basement control, but are believed to have decreasing dip with depth and die out in incompetent strata which underlie the coastal sediments. These faults are normal down-to-the-coast faults and many have been termed “growth faults”.

The Coastal Plain is a wedge of sediments which thickens outwards towards the coast. This column of material is likely to be still undergoing consolidation and, therefore, subsidence. At depth there are incompetent strata which dip towards the coast in conformity with the rest of the sedimentary strata.

Perhaps the weakest of such beds is the Louann Salt of Jurassic Age, the distribution of which is shown on Figure 2.5.2-10. The Coastal Plain sediments are believed to move toward the Sigsbee Deep in the center of the Gulf of Mexico under the influence of gravity. The rate of flow of the incompetent bed, being greater than that of the overlying beds, creates tensional stresses in the overburden. Shearing as well as plastic deformation takes place in these beds. This leads to movement along what are termed “growth faults”.

There is clear field evidence to indicate that the growth faults increase in amount of displacement and decrease in dip with depth. Evidence strongly suggests that they flatten to a bedding-plane fault where they reach a sizeable incompetent bed. They do not appear to extend into the basement complex. Detailed seismic work recently undertaken offshore by the major oil companies has disclosed the presence of parallel ridges which in all likelihood represents the “toeing out” of these large mobilized blocks which may be likened to immense landslides.

This “shallow tectonic” activity does not lend itself readily to earthquakes because of the great thickness of soft unconsolidated sediments which behave plastically, absorbing the strain.

The closest approach of the Gulf Coast Tectonic province to the site is 180 miles.

2.5.2.3 Correlation of Epicenters with Geologic Structures or Tectonic Provinces

The relationship of epicentral locations of earthquakes to tectonic features is discussed in this section. An attempt is made to associate historic earthquakes with active tectonic structures, such as faults or orogenic belts. The procedure adopted for establishing the distance of possible future events from a site is to assume that past events associated with an active structure can occur anywhere along that structure, including its point of nearest approach to the site. In the absence of such relationships earthquakes are regarded as random within the tectonic province with which they are associated.

Figure 2.5.2-2 was prepared primarily to relate historical seismic events to tectonic structures or tectonic provinces based on careful consideration of geologic evidence including geologic history. The classification of tectonic provinces represents regional interpretation based on gross structural geologic characteristics, crustal structure and geologic history. Each of the major provinces can be subdivided into tectonic subprovinces based on an understanding of more definitive structural criteria and the interaction of structural elements throughout geological time. Although genetically related to the major province, each subprovince can be defined by its unique structural characteristics.

Detailed discussion of the tectonic provinces and their subdivisions which are pertinent to the development of the SSE for the CPNPP site are presented in Section 2.5.2.2.

The locations of all recorded earthquakes in Texas and adjacent areas (Modified Mercalli intensity IV or greater) are shown on Figure 2.5.2-2.

2.5.2.3.1 West Central Texas Tectonic Province

All recorded events, except one, have occurred in the Central Basin Platform subprovince. These events are all over 200 miles from the site and in each case appear to be related to local basin formation.

One Intensity IV-V has been reported in the Basin subprovince. This event occurred in an area of recurrent seismic activity and block faulting on the Central Basin Platform. This activity may be associated with petroleum production. No events have been reported in the Central Texas Shelf subprovince, in which the site is located.

2.5.2.3.2 Wichita Tectonic Province

There has been one Intenisty VII event within the Wichita Province and several V to VI events. The largest event occurred in the Anadarko Basin subprovince near the border of the Seminole-Nemaha Uplift Province. This event has been attributed to the Nemaha fault [27] but may well be more characteristic of the Anadarko basin. Recurrent seismic activity is associated with this area as revealed by earthquakes in 1918, 1929, 1933, 1952, and 1953.

The concentration of events in the Amarillo Uplift area is likely attributable to petroleum production, or associated water flooding [25]. At least one event, however, near Lake Meredith, may be the result of crustal loading by this body of water [25].

There is also some possibility that mountain building in the Wichita mountains is still continuing.

The nearest event to the site in the Wichita Province is an Intensity IV, 70 miles from the site and located on the Munester Arch.

2.5.2.3.3 Seminole Arch-Nemaha Uplift Province

This province is just over 190 miles from the site and has experienced no event larger than Intensity VII. Recurrent seismic activity appears to be confined principally to buried block faults in the Precambrian basement along the Nemaha and Seminole arches.

The closest event to the site occurred in 1959 with an intensity of V.

2.5.2.3.4 Ouachita Tectonic Province

This province has experienced twelve events of Intensity V, two of Intensity VI, and one of Intensity VII.

The 1882 Intensity VII event near Paris, Texas has been associated with the buried Arbuckle Mountains under the Ouachita folded belt in the northern portion of he Wichita-Ouachita subprovince [65]. The Intensity VII event occurred approximately 155 miles from the CPNPP site.

Minor seismicity appears to be spatially associated with the thrust faults of southeastern Oklahoma. South central Arkansas also has experienced a significant amount of seismic activity which suggests a continuation of the thrusts of southeast Oklahoma to the east in Arkansas.

2.5.2.3.5 Mesozoic Shelf Tectonic Province

Several earthquakes have been reported in the Mesozoic Shelf Province, with the largest being an Intensity VII near Rusk, Texas. The Rusk event occurred in the Mt. Enterprise subprovince which contains a discontinuous series of narrow grabens representing response to tensional forces generated by a draping of sediments across the southern rim of the East Texas Embayment.

Several earthquakes have occurred in or bordering on the area of the Sabine Uplift. The closest to the site is over 150 miles. These include a 1940 MM IV event in extreme northwestern Louisiana and a series of four events in 1957 in northeastern Texas, all of which are located in the proximity of the Rodessa Fault Zone which is located in the northwestern flank of the uplift. Other events associated with the Sabine Uplift are the series of quakes ranging from MM IV-V that occurred in the Pineland-Hemphill area along the Texas-Louisiana border in 1964. These events are located on the south flank of the Sabine Uplift and at the juxtaposition of the southward trending Sabine Arch with the eastward trending gulfward edge of the Mesozoic Shelf Tectonic Province.

2.5.2.3.6 Balcones-Mexia-Talco Tectonic Province

This province has experienced very little activity, the largest event being an Intensity V-VI near Mexia, Texas in 1932. This event was felt in an area of only 1,000 square miles indicating a very shallow focus [33,61]. Sellards [33] states that the focus for the event was in the Mexia-Talco Fault Zone, west of the town of Mexia. There is also the possibility that the event was caused by oil and gas in the Mexia Field.

2.5.2.3.7 Gulf Coast Tectonic Province

The Gulf Coast Province has experienced several events of low intensity (IV-VI) with the larger events occurring over 200 miles from the site. No major activity has been reported in this province and, due to its distance from the site (approximately 183 miles), it is not significant to the CPNPP site.

The largest historic event (MM VI) occurred near Donaldsonville, La. at a distance of approximately 425 miles from the site. This event is believed to be associated with crustal loading resulting from the deposition of vast quantities of Mississippi River sediments gulfward of that area.

2.5.2.3.8 Far West Texas

In far west Texas, several earthquakes have been recorded, including the highest intensity disturbance experienced in the state (Valentine earthquake of Intensity VIII in 1931). These earthquakes occurred in a heavily faulted area along the southwest margin of the Marathon Basin. Structures there have a northwest orientation, normal to the usual strike of Balcones-Luling-Mexia fault systems. This northwest trending structure has recently been termed the “Texas Lineament.” The structure has not been precisely defined, but possibly represents a late Paleozoic fault zone along which significant right lateral displacement has occurred. The presence of several thermal springs in the vicinity of the Lineament may be noteworthy as they are the only occurrences of thermal springs in Texas [34, 35]. Frequently, thermal springs are associated with active tectonic structures. Their absence over the remainder of the state may be significant. The Texas Lineament is nowhere presumed to be closer than 250 miles to the site.

2.5.2.4 Maximum Earthquake Potential

The historic earthquakes of greatest intensities applicable to site seismic design criteria are the 1882 Intensity VII Paris earthquake, the 1891 Intensity VII Rusk earthquake, and the 1932 Intensity V-VI Mexia earthquake. The only larger event in Texas is the 1931 Intensity VIII Valentine earthquake in west Texas; however, the epicenter is 400 miles from the site and not within a tectonic province within 200 miles of the site. A recurrence of the Valentine event would not result in significant ground motion at the site.

In order to evaluate the effect of earthquakes in surrounding provinces on site ground motion, conservative attenuation curves (based on past Texas and Oklahoma earthquakes) were developed. Attenuation curves were developed by using the maximum epicenter-isoseismal distance for each of three historic earthquakes. The curves are based on the 1882 Paris, the 1931 Valentine, and the 1952 El Reno earthquakes. These curves are shown on

Figure 2.5.2-14. The Bonham, Texas and El Reno, Oklahoma events were used for the Intensity VII curve and the Valentine event for the intensity VIII.

No preferential attenuation or areal perceptibility considerations were employed to increase the attenuation characteristics observed in order that the curves be adequately conservative. Comparison of the attenuation-distance relations shown in Figure 2.5.2-14 with similar relations proposed by Gupta and Nuttli [121], Howell and Schultz [122], and Cornell and Merz [123] indicates that in each case the observed attenuation does not exceed that recognized by the authors.

Using these curves and the conservative acceleration versus intensity relation proposed by Trifunac and Brady [62], the effect of earthquake activity in each tectonic province and subprovince was evaluated. Mean values of peak acceleration [62] were used for evaluation of accelerations from each earthquake intensity after conservative attenuation to the site. Resulting acceleration values, presented in Table 2.5.2-3, are considered very conservative.

Where events cannot be assigned to a specific structure in a subprovince, they are assumed to occur at the nearest point of that subprovince to the site. Using this procedure, the highest intensity possible at the site is a moderate IV resulting from a Modified Mercalli Intensity VII assumed to occur at the closest approach (70 miles NE of the site) of the Wichita-Ouachita Subprovince to the West Central Texas Tectonic Province. This results in a ground acceleration of 0.10 g at the site.

Good agreement is found using the method described by Howell [109] in which an Average Regional Seismic Hazard Index (ARSHI) for the area is defined between 5.22 and 5.70. This method is based on seismic energy release. Since ARSHI values are identical to intensity for any single earthquake a measure of conservatism is therefore demonstrated by choosing a moderate intensity VI as the maximum potential earthquake.

Consideration also has been given to on-site ground motion related to larger historical events originating beyond 200 miles and extrapolated to the site. The largest known events would not have shaken the site at intensities higher than III or IV. This would be the level of the historical events of a New Madrid shock [115, 116] migrated closer along related structures southward, or a Valentine event migrated closer southeastward along related structure.

In summary, the maximum ground motion which conservatively should be postulated for a Maximum Potential Earthquake would result from the occurrence of an earthquake equal to the 1882 Intensity VII shock near Bonham, Texas. Ground motion from this event, minor local events, or large distant shocks would produce horizontal ground motion at the site less than or equal to 0.10 g.

2.5.2.5 Seismic Wave Transmission Properties of the Site

To determine seismic wave transmission and other physical properties of the subsurface material, the following geophysical studies were conducted at the Station and Safe Shutdown Impoundment Dam Areas:

1. Seismic refraction surveys to evaluate the compressional waver velocities of bedrock and the materials overlying bedrock and to evaluate the depth to bedrock;

2. Uphole velocity surveys to provide additional data regarding compressional wave velocities of bedrock and materials overlying bedrock;

3. A surface wave survey to evaluate types of surface waves and their characteristics;

4. Preexcavation crosshole shear wave surveys to evaluate shear and compressional wave velocities of bedrock and the materials overlying bedrock;

5. Postconstruction crosshole seismic wave survey to evaluate shear and compressional wave velocities of a 500-ft thick bedrock interval below plant-grade, with a particular emphasis on claystone interbeds;

6. Ambient noise studies to evaluate the predominant characteristics of groundmotion due to background noise level; and,

7. Gamma ray and electrical resistivity logs in the Squaw Creek Dam site borings, and gamma-ray, gamma-gamma (density), electrical resistivity, and caliper logs in borings S-1A, L-1, and L-2 at the Station site to evaluate strategicgraphic features and obtain rock physical properties at various depths.

Details of the geophysical surveys and results are tabulated and discussed in Section 2.5.4.4.

The properties of the materials underlying the site are described in Section 2.5.4.2. All major structures will be founded on sound bedrock. The low level of anticipated as well as past seismic activity at the site is further improved by the conservative assumptions applied to identify the maximum potential earthquake for design purposes. Therefore, detailed analysis of the seismic wave transmission characteristics of the site is not considered necessary.

2.5.2.6 Safe Shutdown Earthquake (SSE)

A conservative Safe Shutdown Earthquake having a peak horizontal ground acceleration at the top of bedrock of 0.12 g has been selected for design.

Design response spectra and artificial time-history records are described in Section 3.7.1. SSE selection has been based on a conservative evaluation of the level of ground motion that is remotely possible considering seismic and tectonic history and geologic structure.

2.5.2.7 Operating Basis Earthquake (OBE)

In accordance with 10CFR100, Appendix A, the Operating Basis Earthquake is defined to be equal to 1/2 the SSE (i.e. the horizontal ground acceleration at the top of the bedrock has been selected to be 0.06 g, 1/2 the SSE acceleration).

Using the seismic source areas proposed by Algermissen and Perkins [110] the horizontal acceleration in rock with ninety percent probability of not being exceeded in fifty years is five percent of gravity (0.05 g) for southeast central Oklahoma and correspondingly less for the site vicinity. Based on the probabilistic assessment and the historical record it is unlikely that any acceleration corresponding to the OBE would be experienced during the life of the facility.

The Seismic System Analysis (Refer to Section 3.7.2) utilized OBE=1/2 SSE for all stress and deformation criteria.

2.5.3 SURFACE FAULTING

No evidence of surface faulting was found within five miles of the site. For a detailed description of the site geology see Section 2.5.1.

2.5.4 STABILITY OF SUBSURFACE MATERIALS & FOUNDATIONS

2.5.4.1 Geologic Features

Geologic considerations relating to stability of subsurface materials are described in Section 2.5.1.2.6.3. In support of the discussion presented in Section 2.5.1.2.6.3, no evidence of solutioning or past solution activity has been observed in any excavations made in the unweathered Glen Rose Limestone.

The geological history of the site area is presented in Section 2.5.1.2.2.

The information pertaining to the site foundation medium, particularly the data generated from the postconstruction S/L cluster borings (S-1, S-1A, L-1, and L-2) by a detailed seismic crosshole survey, geophysical logging, continuous coring, and dynamic testing of representative core samples [131, 132], was used to divide the subsurface materials underlying the site to a depth of 500 ft into intervals on the basis of their lithologic characteristics and, consequently, engineering properties. These intervals are identified in Table 2.5.4-5E by stratigraphic units, prevalent lithologies, and ranges of thickness, depth and elevation. The depths and elevations shown on Table 2.5.4-5E apply to the vicinity of the power block area. Due to the slight eastward dip of the strata (Section 2.5.1.2.4), these depths and elevations differ slightly for other locations.

2.5.4.2 Properties of Subsurface Materials

The subsurface materials of Cretaceous age, which underlie the site to a depth of apporximately 444 ft (elevation 366 ft) have been sampled and laboratory tested for a wide range of physical and chemical properties. The materials of the Glen Rose Formation, extend from elevation 810 ft (plant grade) to elevation 610 ft and consist of light-to-dark gray argillaceous limestone with lenses and zones of gray to greenish-gray calcareous claystone. The materials of the Twin Mountains Formation, extend from elevation 610 ft to elevation 366 ft and consist of interbedded claystone and sandstone sequences.

The static engineering properties of the subsurface materials underlying the site to a depth of about 50 ft (from plant grade at elevation 810 ft to elevation 760 ft) were determined in the preexcavation stage of the site geotechnical investigations. These properties are discussed in Section 2.5.4.2.1. The dynamic engineering properties of the subsurface materials underlying the site were studied in both the preexcavation and the postconstruction stages of the site geotechnical investigations. The preexcavation investigations were conducted at a number of locations, and were effectively limited to a depth of 200 ft (although some boreholes were drilled to a maximum depth of 400 ft). The postconstruction investigations reached a depth of 500 ft at the location represented by the S/L cluster borings. The dynamic engineering properties are discussed in Section 2.5.4.2.2.

2.5.4.2.1 Static Engineering Properties

The static strength and other physical properties of the upper portion of the Glen Rose Formation (Zone I and the top of Zone II) were determined in the laboratory by means of the following types of tests:

1. Unconfined compression tests.

2. Bulk modulus of elasticity determination.

3. Double ring shear test.

4. Brazil tension test.

5. Unit dry weight determinations.

6. Poisson's Ratio determination.

A considerable number of selected representative specimens of the rock formation were subjected to unconfined compression tests. The unconfined compression tests were conducted in accordance with standard ASTM Procedures. On a number of the samples, vertical strain was measured by means of a dial micrometer in order that the stress-strain (bulk modulus) relationship could be determined. The results of the unconfined compression tests are shown on Table 2.5.4-1. The results of the stress-strain (Young's modulus) observations made on the selected specimens during the unconfined compression test procedure are shown in graphical form on Figures 2.5.4-1 (Sheets 1 thru 25).

Triaxial compression tests were conducted on selected claystone samples. A listing of the samples tested is given below:

Boring No.	Sample No.	Depth, Feet	Lab No.	Length, Inches	Diameter Inches
P-25	W-34	76.0-77.0	1	4.465	2.010
P-25	W-34	76.0-77.0	2	4.350	2.018
P-25	W-28	64.0-65.0	3	4.500	2.045
P-25	W-28	64.0-65.0	4	4.395	2.048
P-25	W-73	154.0-156.0	5	4.345	2.065
P-25	W-73	154.0-156.0	6	4.638	2.065

Each sample was subjected to a back pressure of 200 PSI and the claystone was essentially saturated as full pressure response was noticed during the test. Higher saturation pressure (greater than 200 PSI) was not desirable since such greater pressures accelerate consolidation and reduce permeability. A typical stress-strain curve (Lab Number 4) is shown on Figure 2.5.4-2 and a Mohr Diagram for each of the samples tested is shown as Figure 2.5.4-3.

The ratio of lateral strain to vertical strain, Poisson's Ratio, was determined on two selected typical samples of claystone and three selected typical samples of limestone. Both directions of strain were measured using SR-4 Resistant Wire Strain Gauges attached to the surface of the sample by means of appropriate adhesives. As many as four cycles of axial load application were made in order to fully investigate stress-strain characteristics of the typical materials. The results, in graphical form, of these determinations are shown by Figures 2.5.4-4 through 2.5.4-13, inclusive.

The double ring shear strength of selected typical rock samples was determined in pre-chosen direction essentially parallel to the bedding planes. The double ring shear test apparatus consists of three parallel steel plates with openings of a size very slightly greater than the sample diameter. Two of these steel plates are supported on horizontal base and, in turn, support the rock specimen. The third plate or ring, which is sandwiched between the outer plates, acts as a loading device and is allowed to react with the specimen. The results of these determinations are shown on Table 2.5.4-2.

The tensile strength of selected and typical rock materials were determined by the Brazil tension test. These tests are accomplished by placing a rock specimen horizontally between two bearing plates and loading in compression until failure occurs in tension. The results of these determinations are shown in summary form on Table 2.5.4.-3.

Table 2.5.4-4 is a summary of the static rock properties for the upper portion of the Glen Rose Formation on which the major plant structures were found.

2.5.4.2.2 Dynamic Properties of Subsurface Materials

The dynamic properties of the subsurface materials were determined by field geophysical surveys conducted in both the preexcavation and the postconstruction stages of the site geotechnical investigations, and by laboratory testing of rock core samples obtained from deep postconstruction borings S-1, S-1A, and L-2 which were drilled together with boring L-1 for a detailed crosshole seismic survey. The scope and the results of the geophysical surveys are presented in Section 2.5.4.4. Discussion of the laboratory testing is included in this section.

The laboratory testing program included measurement of unit weights and performance of resonant column testing (which provided shear moduli and damping properties). Out of 79 core pieces delivered to the laboratory, 64 were tested; all of them for unit weight, and 17 were subjected to resonant column testing. These samples were taken from the S/L cluster borings between elevation 809 ft and elevation 428 ft. Within this depth interval of 381 ft, 30 samples were obtained from the Glen Rose Formation (17 claystone, 12 limestone, and 1 sandstone sample), and 34 samples were obtained from the Twin Mountains Formation (11 claystone, 3 limestone, and 20 sandstone samples). A summary of the laboratory test results [132] is shown on Table 2.5.4-5G. Reference 132 discusses the details of the test program and presents data on the variation of shear modulus and critical damping with strain levels.

Considering the ranges of stiffness indicated by Tables 3.7B-24 through 29, and by inspection of the sensitivity of the elastic expressions listed in Tables 3.7B-5 and 6 to variation in shear modulus (G) and Poisson's ratio (ν), it is evident that the profile stiffness represented on Table 2.5.4-5H lies within the ranges of stiffness indicated by Tables 3.7B-25 through 29. On this basis, the additional information provided by the postconstruction geophysical survey generally confirms the validity of the profile stiffness represented on Table 2.5.4-5.

2.5.4.2.3 Rock Core Compositional Analyses

Petrographic, solubility, x-ray and chemical analyses were performed on ten cores of Glen Rose and Twin Mountains formations. These tests indicate that both the Glen Rose and Twin Mountains formations are not susceptible to solutioning which verifies field observations and experience.

1. Petrographic Analysis

The cores were slabbed lengthwise and one slice was kept intact and prepared for observation. It was ground on 220, 400, and 600 grit grinding powder, washed, then etched for 3 seconds in 10% HC1 solution, washed, and dried. The procedure was completed for all cores as well as for the rock chips remaining from the thin sections that were prepared. The etched slabs were examined under binocular microscope.

Thin sections were made for each core and were ground to a thickness of approximately 18 microns, after which petrographic modal analyses were completed for each thin section. All work was done on Leitz Dialux-Pol polarizing research microscopes. The description terminology is standard Fold Carbonate Classification with the textural packing classification of R. Dunham added as a supplement. Both classifications are described in detail in American Association of Petroleum Geologists Memoir 1 on the Classification of Carbonate Rocks (ca 1962). Three thin sections were prepared from the cores from borings P-9 and P-10. Single thin sections were prepared from all other cores. Detailed results of the petrographic analyses are given in the following sections.

1.1 Boring P-9 Depth 124 to 124.5 Feet

Core Description: Limestone, calcitic mud; stratification very irregular, lensing, very thinly laminated (fraction of mm) to very thin bedded (circa 2 cm). Lenses are flattened parallel to stratificated plans, are 1x2 mm; are made of light gray lime mud (5Y 7/1) bounded by darker very thin laminae (gray-5Y 5/1) which are laterally discontinuous.

Porosity: low, 1-3% prior to slabbing. Discontinuous pockets, a maximum of 1/4 inch in size, of lightly cemented material are present which disintegrate upon contact with water. These are isolated from each other and are apparent organic burrow fillings. Thus, porosity created by opening of these pockets is not effective.

Grain Orientation: Generally poor due to the moderate to strong bioturbation of sediment. Post-depositional compaction has improved grain alignment parallel to stratification. Most of the lenses were originally round or oval-shaped animal burrows; some were simply sea-floor depressions that were filled by mud and later flattened somewhat.

Thin section Analyses - Carbonates - (Summary of three sections)

I. Complete Lithic Name (Folk-Dunham): Slightly sandy, disturbed, ostracod/mollusca, bio-pelmicrite, wackestone

II. A. Allochem Total: 45%

Pellets: 21%

Biogenic: 23%

Others: Carbonaceous plant detritus

Phosphatic fish remains (less than 2%)

B. Matrix: 45% (incl. 5% secondary dolomite)

Sparry Cement: less than 1%

Porosity: less than 2%

Terrigenous Material: approximately 10-12%

III. Composition (detailed description of items under “II”):

Biogenic: Ostracods, Mollusca, Foraminifera Plant, Phosphate

Pellets: mean size = 0.110-0.115 mm, more concentrated in burrows\

Terrigenous Material: visible quartz, opaque minerals. Qtz = med. silt to v.f. sand, mean size = 0.070mm, sub- angular to angular. Opaque minerals = pyrite, iron oxide.

Matrix: micritic calcite predominately; dolomite euhedral rhombs (0.020-0.025mm) average about 5% throughout all thin sections of P-9, reaches 20%+ within individual burrows.

Cement: Sparry calcite, primarily within tests of organisms

IV. Texture:

A. Grain size (mean, sorting): Mean grain size = medium silt; sorting poor (0.02-0.03mm)

B. Orientation/Bioturbation: Medium to highly biogenically disturbed. Burrowed zones sharply defined by disturbances of grain orientation.

C. Compaction: Moderate compaction - burrows shells compressed.

D. Resedimentation/Abrasion: None except for movement during bioturbation.

E. Diagenesis: Dolomite is secondary, common in sediments with high content of organic matter initially (especially in muds)

V. Depositional/Environmental Interpretation:

Low energy, carbonate mudflat, probably lagoonal/restricted circulation. Fine terrigenous material probably introduced during storms, then reworked by burrowing infauna (e.g. worms, crustaceans)

VI. Other Notes: Most of the pore space in the thin sections due to plucking of softer clay-rich material during section grinding, i.e., this is not original porosity.

1.2 Boring P-10 Depth 114 to 114.5 Feet

Core Description: Limestone, muddy carbonate (calcitic) sand; stratification very irregular, thin to medium bedded, very discontinuous laterally. Patches of finer calcitic mud, internally laminated, that appear identical to the general P-9 lithology (confirmed in thin section examination). These patches are renants that were not removed by the bioturbation which dominates in the rest of the slab. That other P-9 type sediment has been reworked is indicated by the lithoclasts that are present in the carbonate sand of the slab and in thin section. Some of the reworking was by mechanical wave action, some by burrowing organisms.

Porosity: Low, probably less than 5%. Some discontinuous pockets of coarse-grained carbonate sand are weakly consolidated and with some porosity; this porosity is not effective. Compaction of sediment is moderate.

Grain Orientation: Generally poor due to moderate bioturbation of sediment. The bulk of the common sandsize carbonate was deposited under conditions of relatively high wave and/or current energy with probably very good initial grain orientation. Subsequent reworking by organisms has destroyed this. Sorting is poor with both mud and calcite spar-cemented patches of grains.

Thin Section Analysis - Carbonates - (Summary of three sections)

I. Complete Lithic Name (Folk-Dunham): Disturbed, foraminiferal molluscan biosparite/biomicrite-Packstone

II. A. Alochem Total: 80%

Intraclasts: 5%

Pellets: 10%

Biogenic: 65%

B. Matrix: 7-12%

Sparry Cement: 12-7%

Porosity: less than 5%

Terrigenous Material: less than 3%

III. Composition (detailed description of items under “II”:

Biogenic: Foraminifer (Milliolid-types) Mollusca (pelec., gast.) Echinodermata Ostracods

Pellets: very fine-fine grain sand size

Intraclasts: micritic, to 2.5mm in diameter. Often terrigenous, with P-9 lithic type.

Terrigenous Material: Very fine quartz, pyrite, ferrug. opaques. Pyrite generally filling some foram chambers.

Matrix; Cement: Calcite, only trace of dolomite seen. Both are quite variable in distribution due to the bioturbation; cement is not only in voids of tests, between grains, but also within micrite envelopes developed on molluscan debris.

IV. Texture

A. Grain size (mean, sorting): Mean grain size. 0.35- 0.375mm, sorting poor; patchy distribution of micrite, both within tests and as intersititial matrix.

B. Orientation/Bioturbation: Generally random grain orientation due to extensive bioturbation.

C. Compaction: Moderate, no severe crushing of shells

D. Resedimentation/Abrasion: Local resedimentation, indicated by presence of intraclasts, commonly of P-9 type. Abrasion neglible.

E. Diagenesis: Micrite envelopes due to algal boring (of fungal activity) are extensively developed on most pelecypod material; internal aragonite is dissolved and replaced by calcite. Calcite spar cement looks like vadose zone development.

V. Depositional/Environmental Interpretation:

Higher energy situation than for P-9. Possible intertidal zone on well circulated carbonate mudbank. Could be in same setting as that for P-9, but with better water circulation and higher energy.

Large patches of P-9 type sediment (silty mud) are present in upper part of core P-10 and were verified in thin section P-10C.

1.3 Boring P-10A Depth 70.8 - 71.2 feet

Core Description: Mudstone, dolomitic, silty laminated. Laminae disturbed by burrowing organisms. Sample light gray (5Y7/1 dry).

Porosity: 3%. Burrowed zones may have slightly higher porosites due to concentration of dolomite and silt size material.

Grain Orientation: Good, evidenced by laminations attributed to alignment of clay minerals.

Thin Section Analysis - Clastics

I. Complete Lithic Name: Dolomitic silty mudstone.

II. Composition:

Quartz: 15%

Organic: 1%

Pyrite: 3%

Matrix: 80%

Matrix primarily clay minerals, silt size quartz and 15-20T dolomite ranging in size from 0.004 mm to 0.025 mm, mean grain size 0.015 mm.

III. Texture:

A. Size Range: 0.048 coarse silt to clay sized material. Mean grain size is in the clay size range.

B. Sorting: well sorted

C. Orientation: Good. Attributed to clay minerals.

D. Porosity: 3%

E. Compaction: Fair amount of compaction.

F. Diagenesis: Secondary dolomite

IV. Depositional/Environmental Interpretation:

Low energy, probably a lagoonal deposit.

1.4 Boring P-10A Depth 141.0 - 141.8 feet

Core Description: Limestone, calcitic mud; thinly laminated to thinly bedded. Stratification very irregular with laminae laterally discontinuous. Lenses common and flattened parallel to the stratification plane. Lenses range up to 1 x 4 cm. and are composed of light gray to light olive gray lime mud (5Y6/1.5) bounded by darker laminae light gray (5Y7/1) which are laterally discontinuous. Most lenses appear to be burrows flattened by compaction.

Porosity: Low, 3%. The darker laminae are easily disintegrated upon contact with water due to the presence of expandable clays. These laminae are cut by lenses (burrows) which are little affected by water contact.

Grain Orientation: Poor due to moderate bioturbation of the sediment. Post-depositional compaction has flattened the lenses and aligned some grains parallel to stratification.

Thin Section Analysis - Carbonates:

I. Complete Lithic Name (Folk-Dunham): Disturbed, silty, dolomitic Molluscan Biomicrite-Wackestone.

II. A. Allochem Total: 25%

Intraclasts: 2%

Pellets: 6%

Biogenic: 17%

B. Matrix: 58%

Sparry Cement: --%

Porosity: 3%

Terrigenous Material: 8%

Pyrite: 5%

III. Composition (detailed description of items under "II"):

Biogenic: Molluscan (concentrated in burrows)

Intraclasts: Micritic to 2.4mm in diameter

Terrigenous Material: Visible quartz, medium silt to very fine sand size (concentrated in burrows)

Matrix: Fine dolomite crystals abundant in matrix. Size range 0.021 mm - 0.002 mm. Mean grain size = 0.008 mm.

IV. Texture:

A. Grain size (mean, sorting); Poor sorting within burrows, mean grain size in burrows 0.30 mm.

B. Orientation/Bioturbation: Random grain orientation within burrows.

C. Compaction: Moderate -- no severe crushing of shell debris.

D. Resedimentation/Abrasion: None except for bioturbation.

E. Diagenesis: Diagenetic formation of dolomite.

V. Depositional/Environmental Interpretation:

Low energy, carbonate mudflat deposit, restricted circulation. Dolomite burrowed by infauna and terrigenous material as well as molluscan fragments and intraclasts introduced in burrows.

1.5 Boring P-10A Depth 223.5 - 223.8 feet

Core Description: Limestone, calcitic mud; thinly laminated to thinly bedded. Stratification very irregular with laminae laterally discontinuous. Lenses are common and flattened parallel to the stratification plane. Lenses observed range in size from 1 x 2 mm to 1 x 2 cm. and are composed of white to light gray lime mud (5Y8/1 - 5Y7/1) bounded by darker laminae gray (5Y6/1). Most of the lenses appear to be burrows which were originally round or oval shaped and since flattened by compaction.

Porosity: low, 2%. A few pockets of expandable clay are present which disintegrate upon contact with water. These pockets or lenses apparently isolated animal burrows. Porosity is not improved by solutioning of these isolated lenses.

Grain Orientation: Poor due to moderate to intense bioturbation of the sediment. Post-depositional compaction has realigned some grains parallel to stratification.

Thin Section Analysis - Carbonates:

I. Complete Lithic Name (Folk-Dunham): Disturbed, slightly silty, obstracod/Mollusca biomicrite-Packstone.

II. A. Alochem Total: 80%

Intraclasts: 2%

Pellets: 15%

Biogenic: 43%

Bryozoan coated grains: 20%

Organic and phosphatic remains: 1%

B. Matrix: 7%

Sparry Cement: 5-8%

Porosity: 2%

Terrigenous Material: 5%

III. Composition (detailed description of items under “II”):

Biogenic: Ostracod-foraminifers Mollusca Echinodermata Bryozoa

Terrigenous Material: Quartz, medium silt to fine sand.

Matrix: Predominantly micritic calcite, minor amount of dolomite.

Cement: Sparry calcite primarily within tests of organisms.

IV. Texture:

A. Grain size (mean, sorting): Poor sorting due to bioturbation. Mean grain size 0.21 mm to 0.30 mm.

B. Orientation/bioturbation: Medium to highly bioturbated, random grain orientation.

C. Compaction: Moderate -- Burrows and shells compressed.

D. Resedimentation/Abrasion: None except for bioturbation. Burrows commonly mud and/or spar rich.

E. Diagenesis: Secondary dolomite.

V. Depositional/Environmental Interpretation:

Low energy, carbonate mudflat, restricted circulation, possibly lagoonal. Material reworked by burrowing infauna. Terrigenous material possibly introduced and concentrated by burrowing organisms from adjacent strata.

1.6 Boring P.10A Depth 242.3 - 242.6 feet

Core Description: Sandstone, fine grained quartz sand, gray (5Y6/1 dry). Cross stratified non-cemented, very friable although well compacted.

Porosity: 10-12%. Moderate to well compacted sandstone accounting for relatively low porosity.

Grain Orientation: Poor grain orientation. Locally organic material concentrated along stratification planes.

Thin Section Analysis - Clastics:

I. Complete Lithic Name: Fine-grained quartz arenite (Orthoquartize)

II. Composition:

Quartz: 90%

Chert: 2%

Feldspar: 1%

Rock Fragments: 1

Pyrite: 2%

Organic: 2%

Matrix: 2%

Carbonate and clay matrix (carbonate 1%)

III. Texture:

A. Size Range: 0.39mm (medium sand) to 0.02 mm (medium silt). Mean grain size 0.127mm (fine sand).

B. Sorting: Well sorted.

C. Textural maturity: Mature

D. Roundness: Subangular to rounded.

E. Orientation: Weak

F. Porosity: 10-12%

G. Compaction: Moderate to well compacted - pressure solutioning minimal.

H. Diagenesis: Minor overgrowths.

IV. Depositional/Environmental Interpretation: High energy, possibly a barrier bar or beach deposit.

1.7 Boring P-10A Depth 264 - 264.3 feet

Core Description: Sandstone, fine grained quartz sand, light gray (5Y7/1 dry). Stratified, non-cemented, very friable, although well compacted.

Porosity: 12-15% Moderate to well compacted sandstone accounting for relatively low porosity.

Grain Orientation: Weak or poor grain orientation. Sediment slightly bioturbated with burrows higher in clay content.

Thin Section Analysis - Clastics:

I. Complete Lithic Name: Fine-grained Quartz arenite (orthoquartzite).

II. Composition:

Quartz: 91%

Feldspar: 1%

Organic: 1%

Chert: 2%

Rock Fragments: 1%

Pyrite: 1%

Matrix:

Carbonate: 2%

Cement: 0%

III. Texture:

A. Size Range: 0.30mm (medium sand) to 0.06 (silt, very fine sand). Mean grain size 0.012 (fine sand).

B. Sorting: well sorted

C. Textural Maturity: Mature

D. Roundness: Subangular to rounded.

E. Orientation: Weak.

F. Porosity: 12-15%

G. Compaction: Moderate to well compacted - pressure solutioning minimal

H. Diagenesis: Minor quartz overgrowths.

IV. Depositional/Environmental Interpretation:

High energy, possibly beach or barrier bar deposit.

1.8 Boring P-10A Depth 282.2 - 282.5 Feet

Core Description: Sandstone, very fine grained, poorly sorted quartz sand. Stratification disturbed by burrowing organisms. Burrows light gray (5Y6.5/1) dry), sand white (5Y8/1 dry).

Porosity: 7-10T Moderate to well compacted sand. Burrows have poor porosity due to concentration of clay minerals.

Grain Orientation: Weak or poor grain orientation due to bioturbation.

Thin Section Analysis - Clastics:

I. Complete Lithic Name: Very fine grained Quartzwacke.

II. Composition:

Quartz: 67%

Feldspar: 1%

Rock Fragments: 1%

Organic: 1%

Matrix: 31% Predominantly silt size quartz and clay.

III. Texture:

A. Size Range: 0.204mm (fine sand) to clay sized material. Mean grain size 0.102mm (very fine sand).

B. Sorting: Poor sorting.

C. Textural Maturity: Immature.

D. Roundness: Subangular to rounded.

E. Orientation: Weak

F. Porosity: 7-10%

G. Compaction: Moderate.

H. Diagenesis: Bioturbated with possible concentration of clay along burrows.

IV. Depositional/Environmental Interpretation

Initial sorting of quartz due to high energy but final deposition probably occurred at low energy due to mixing of clay and sand. Possible beach or dune sand deposited in lagoonal mud by storm winds or waves.

2. Solubility Tests

Eight core samples were tested for solubility. Part of each core was ground to less than 1450 mesh and dried at 105°C. Five grams of ground rock were then agitated for two hours in one liter or distilled water. The resulting solubilities are maximum values due to the slight losses of rock resulting from removal of the water before weighing. The results are presented in Table 2.5.4-8.

In addition, five grams of the cores were treated with 5 percent acetic acid until no more effervescence resulted. The results are presented in Table 2.5.4-8.

The residue from samples from boring P-9 and P-10 were heated to 800°C for four hours which caused a color change.

In addition, five grams of the cores were treated with 5 percent acetic acid until no more effervescence resulted. The results are presented in Table 2.5.4-8.

The residue from samples from boring P-9 and P-10 were heated to 800°C for four hours which caused a color change from black to light brown and weight losses of 11.6 and 12.3 percent respectively. These correspond to a net loss of 1.6 and 0.5 percent of the total sample.

3. X-Ray Analysis

Core samples were run on the x-ray diffractometer. The results are presented in Table 2.5.4-9.

The acetic acid residue of samples were x-rayed with the following results:

SAMPLE	DEPTH	RESULTS
P-9	124	Quartz, dolomite
P-10	114	Quartz, dolomite, pyrite
P-10A	141.1	Quartz, minor illite, montmorillonite
P-10A	223.5	Quartz, minor montmorillonite, illite

Additional x-ray study was conducted on P-9. The finest fraction (2 microns) was found to be mainly calcite with minor quartz. The small, discontinuous, porous portions of the rock are calcite, dolomite, and minor quartz.

Two specimens from the claystone section of the Glen Rose Limestone (core P-10A, 70.8 feet; core P-14, 64 feet) were analyzed chemically (Table 2.5.4-10) and by x-ray diffraction (Table 2.5.4-9). Combined interpretation of x-ray and chemicals data indicates the following approximate clay mineral contents:

	P10A, 70.8 feet		P-14, 64 feet	
Clay Mineral	% of Clay	% of Rock	% of Clay	% of Rock
Kaolinite	45	25	13	5
Illite	55	30	87	35
Montmorillonite	0	0	0	0

Averaging results on the two specimens, the claystone section has the following approximate composition:

Clay Mineral	% of Clay	% of Rock
Kaolinite	29	15
Illite	71	32
Montmorillonite		None Detected

Kaolinite was not detected in core P-14, 64 feet, but its presence is suggested by the ration of A1203/K20 (=4.17) in the chemical analysis. This ratio is higher than the 3.4 A1203/K20 ratio which would be expected in a pure illite.

Montmorillonite was not detected in either specimen. However it could be present below the X-ray diffraction detection limit (5-10% of rock).

If this were the case some of the reported kaolinite would be montmorillonite since both are primarily aluminum silicates.

Montmorillonite was detected in two specimens of Glen Rose Limestone at deeper levels. Approximate clay mineral contents of these specimens are:

	P10A, 141.1 feet		P10A, 223.5 feet	
Clay Mineral	% of Clay	% of Rock	% of Clay	% of Rock
Kaolinite	0	0	0	0
Illite	70	28	50	5
Montmorillonite	30	12	50	5

4. Chemical Analyses

   The core samples were analyzed for metal oxides with an atomic absorption spectrometer. The results are presented in Table 2.5.4-10.

2.5.4.3 Exploration

A comprehensive investigation has been completed to evaluate the subsurface conditions beneath all structures. This exploration consisted, in part, of drilling borings, performing geophysical surveys, installing piezometers and wells, and mapping foundation excavations.

The locations of the borings, wells and piezometers are shown on Figures 2.5.5-5 and 2.5.5-6. The methods used in drilling the borings are discussed in Section 2.5.5.3. The description of the geophysical surveys is presented in Section 2.5.4.4.

Geological cross sections are presented in Figures 2.5.4-40, 2.5.4-41, and 2.5.6-7 through 2.5.6-11. The limits of excavations are shown in Figure 2.5.4-27.

2.5.4.4 Geophysical Surveys

In the preexcavation period, the following geophysical surveys were conducted at the Station and Safe Shutdown Impoundment Dam areas, providing data to depths of 200-ft and 100-ft, respectively:

1. Seismic refraction surveys to evaluate the compressional wave velocities of bedrock and the materials overlying bedrock and to evaluate the depth to bedrock;

2. Uphole velocity surveys to provide additional data regarding compressional wave velocities of bedrock and materials overlying bedrock;

3. A surface wave survey to evaluate types of surface waves and their characteristics;

4. Crosshole shear wave surveys to evaluate compressional and shear wave velocities of bedrock and the materials overlying bedrock;

5. Ambient noise studies to evaluate the predominant characteristics of ground motion due to background noise level; and,

6. Gamma ray and resistivity logs (at Squaw Creek Dam also) to evaluate stratigraphic features.

The locations of surveys 1 through 5 are shown on Figure 2.5.4-14. Locations of borings P-10, M-1, D1-2, D1-8A and D1-9 in which survey 6 was performed are shown on Figures 2.5.5-5 and 2.5.5-6. In the postconstruction period, two methods of geophysical exploration were conducted in the deep S/L cluster borings. Both provided detailed information on rock properties from a 500-ft-thick sedimentary section. These methods were:

- Crosshole measurement of seismic wave velocities on which rock shear modulus and Poisson's ratio were based; and

- Complex borehole logging including gamma-ray, electrical resistivity, gamma-gamma, and caliper surveys. The geophysical logs contributed to the straitigraphic refinement of the drilled column. The gamma-gamma logs also provided in situ densities.

The summary of geophysical test data including pre-excavation survey data and ambient ground motion measurements are provided in tables 2.5.4-5A through 2.5.4-5D.

The geophysical explorations are discussed in detail in the following sections.

2.5.4.4.1 Seismic Refraction Survey

A seismic refraction survey, 4,000 lineal feet in length, was conducted at the Station location along two seismic profiles. A seismic refraction survey (1,500 lineal feet) also was performed at the Safe Shutdown Impoundment (SSI) Dam site. Adjustments were made to seismic line locations where pipelines were present. Seismic energy was produced by detonation of explosive charges (five to 15 pounds of Nitromon-S; a Du Pont product) placed in drilled holes. These holes ranged in depth from five to 15 feet. The energy released by the charges was detected by vertically-oriented geophones spaced at 50-foot intervals along the seismic profiles. The geophones, manufactured by Electro-Tech Labs, have a natural frequency of 14 Hertz (cycles per second) and are fitted with a spike or metal plate to obtain proper coupling with the site materials. The energy impulse received by the geophones was recorded by a Dresser SIE seismic amplifier system coupled with a Dresser SIE R6 recording oscillograph.

The compressional wave velocities and the corresponding depths to bedrock were evaluated by plotting first arrival times of seismic energy at each geophone against the distance of each geophone from the seismic energy source. The time-distance data for each profile and the corresponding subsurface cross sections of the profiles are shown on Figures 2.5.4-15 through 2.5.4-18. Representative compressional wave velocity data determined from the seismic refraction survey (and the uphole survey) are summarized on Tables 2.5.4-5B and 2.5.4-5C. The accuracy of the calculated depths to the bedrock surface is considered to be 10 to 20 percent. This estimate is based on a number of factors. The velocity and characteristics of the near surface materials can introduce some error into interpreted depths. Uphole surveys, an examination of soil and core samples, and an examination of the boring logs were used to reduce this type or error. The timing accuracies of the equipment and the seismic caps also lead to the selection of tolerance which acts as a guide in determining the accuracy of the estimate.

2.5.4.4.2 Uphole Velocity Survey

Uphole velocity surveys were performed at the station and SSI dam locations. These provided a comparison with compressional wave velocities obtained by the seismic refraction surveys at each location. Borings P-1 at the Station location and M-5 on the SSI dam were selected for these surveys. A geophone array was placed on the ground surface around each boring. Small explosive charges were fired at 10-foot intervals from the bottom to the top in each boring. The seismic energy released by the explosives was detected by the geophones in each array. This energy was recorded by the same system that was used in the seismic refraction surveys. The results of the uphole velocity surveys are presented on Figures 2.5.4-19 and 2.5.4-20, as well as on Tables 2.5.4-5B and 2.5.4-5C.

2.5.4.4.3 Surface Wave Survey

A surface wave survey was conducted at the station and SSI dam locations to evaluate the types and characteristics of any observable surface waves.

Two Sprengnether Engineering Seismograph VS-1200, three-component geophones were placed 300 to 350 feet apart on the ground. The output of these geophones was fed into a VS-1100 amplifier with a gain characteristic of 100, and from the amplifier into a special attenuator circuit. The resultant output was recorded on the Dresser SIE R6 recording oscillograph.

Explosive charges were placed in drill holes at varying distances from, but in-line to, the geophones. Explosive charges used in this survey varied from five to 40 pounds of Nitromon-S.

In addition to this procedure, recordings were made of the energy produced by horizontal impacts of an eight-pound sledgehammer. This energy was detected by six one-component (horizontal) geophones spaced five to 20 feet apart.

The compressional and shear wave velocities developed from the surface wave survey are presented on Tables 2.5.4-5B and 2.5.4-5C.

2.5.4.4.4 Crosshole Shear Wave Surveys

Crosshole shear wave surveys were performed at two plant locations and at the SSI dam site utilizing borings drilled into bedrock. These surveys were conducted in two separate time periods; initially, prior to excavation, and subsequently, after construction was essentially completed. The preexcavation survey was made in somewhat different manner than the postconstruction survey. The difference included: the scope and the location of the survey, the techniques applied, and the thickness of the stratigraphic column involved.

During the preexcavation crosshole survey, stationary subsurface shots were used as a source of the seismic energy. Wave propagation from two shot points was recorded in borings P-1 and P-2 at distances ranging from 370 ft to 1,175 ft, and from a single shot point in two preconstruction SSI dam borings M-5 and M-6 at distances of 400 ft and 700 ft, respectively. Compressional and shear wave arrival times were recorded in each of these borings by using 4 to 6 geophones vertically arranged within the upper three zones of the Glen Rose Formation between elevation 650 ft and elevation 818 ft.

For the preexcavation survey, two three-component, low-frequency geophones (Mark Products L-1-3DS) were placed at corresponding elevations deep in each recording borehole. Explosive charges were detonated in drilled holes at fixed distances from each of the borings. The resultant seismic energy was recorded by the Dresser SIE system. After each shot (energy detonation), each geophone was raised 25 feet. Details of the crosshole shear wave survey at both the plant site and the Safe Shutdown Impoundment Dam are presented in Table 2.5.4-5A. In addition to this data, seismic energy developed by a technique of producing horizontally-generated waves was also recorded by each of the geophones at 25-foot intervals. The technique for producing horizontally-generated waves was developed by the Dames & Moore geophysical staff. It involves the use of explosives (Primacord) placed in trenches at the ground surface adjacent to a boring. Two trenches are used, one on either side of a boring. Depending on the site conditions, the trenches vary in length from three to eight feet long, and in depth from six inches to two feet deep. The trenches used on this site were five feet long, and one foot deep. The trenches are “v” shaped with one face cut vertical and the other sloped at some angle to the vertical. This angle will vary for different conditions, but for this survey, an angle of 60 degrees was used. The vertical face of the trenches on either side of a boring are opposed to each other as shown in Figure 2.5.4-21. Primacord is placed in the bottom of each trench and fired simultaneously by the use of seismic caps. The trenches are not backfilled, allowing for a backblast. The resultant detonations produce a horizontal torque, centered around the boring, which is recorded in the boring by use of a three-component geophone.

The results of this survey are plotted as an uphole shear survey, with proper calculations for the shot offset and depth. Primary and secondary arrivals are plotted on a time-depth plot. The plot for the survey at boring M-5 is shown on Figure 2.5.4-21.

Shear wave arrivals often are found to be masked by relatively large-amplitude motions caused by multiple reflected and refracted compressional waves and the surface waves. To overcome this difficulty high-energy and low-energy recordings were made at corresponding depths in each of the borings.

The compressional and shear wave velocities, determined in the initial survey by the crosshole techniques and by the surface wave surveys, are presented on Tables 2.5.4-5B and 2.5.4-5C.

During the postconstruction crosshole survey [131] conducted in four closely spaced, up to 500-ft-deep S/L cluster borings (Figure 2.5.4-14), seismic waves were generated by a vertically mobile hammer inserted in “source” boring S-1A, and these waves were detected by three horizontally separated geophones installed at the same elevation in each of the three “listening” borings: S-1, L-1, and L-2. These three “listening” borings were 5 ft, 8 ft, and 9.5 ft, respectively, away from the “source” boring. The measuring points were located within the interval from elevation 797 ft (12 ft below plant grade), which is within Zone I of the Glen Rose Formation, to elevation 317 ft (492 ft below plant grade), which is beneath the unconformity separating the Cretaceous Twin Mountains Formation from the underlying Paleozoic Mineral Wells Formation.

The postconstruction survey was performed at a location immediately west of the Unit 2 turbine building area (Figure 2.5.4-14A). The survey equipment consisted of a four-channel Nicolet Oscilloscope (Model 4094-2), a Bison shear-wave hammer (Model 1465-1), and three Geospace Geophones (Model HS-J-LP3D). The Bison downhole shear-wave hammer was the energy source. This hammer consists of a stationary body with a sliding mass, and is hydraulically locked in the “source” boring. Using a hoist cable, the mass is lifted or dropped to produce impacts against the stationary hammer body. The hammer, designed to permit either upward or

downward impacts, generates vertically polarized shear waves of opposing polarities. These polarities allow identification of the shear wave arrivals in the presence of refracted or reflected seismic arrivals in layered formations. Crosshole measurements were normally taken at 3-ft intervals from 0 to 45 ft, at 5-ft intervals from 45 to 300 ft, and at 10-ft intervals thereafter. Additional measurements were performed to determine the seismic wave velocities in claystone layers at depths of approximately 20 to 30 ft and 100 ft. Crosshole measurements were taken at a total of 90 elevations, resulting in a total of about 440 individual records. The survey procedures are described below:

- The Bison hammer was suspended in boring S-1A ("source boring") at the desired depth. The hammer shoes were hydraulically extended to clamp the hammer in-place at the elevation.

- Geophones were suspended in borings S-1, L-1, and L-2 ("listening" borings) at the same elevation, and the pneumatic tubes were inflated to couple the geophones to the casing wall.

- Typically, 10 impacts (upward or downward) were performed with the shear-wave hammer.

- The wave motion produced with each individual impact was stored in the Nicolet Model 4094-2 oscilloscope. The motions produced by 10 impacts were averaged to yield one record for that combination of depth, impact direction, and "listening" boring.

- Upon completion of each series of impacts, the data were written onto a floppy disk as a permanent record and labeled to indicate depth, impact direction, and "listening" boring.

- This procedure was repeated such that two records for upward impacts and two records for downward impacts were obtained for each "listening" boring at each elevation.

- Upon completion of the recording sequence, the hammer and geophones were released and advanced to the next recording elevation where the procedure was repeated.

The borings used for the postconstruction crosshole geophysical surveys were cored either continuously (S-1, and S-1A below 325 ft) or partially (L-1 and L-2). They were logged geophysically (except for S-1), cased by PVC pipe which was grouted (except for S-1), and subjected to a verticality survey to allow accurate determination of interhole separation at all depth levels where crosshole seismic velocity measurements were made.

Generalized subsurface conditions at the location of the S/L cluster borings are shown in Figure 2.5.4-30A which includes a generalized geologic column, the geophysical logs of boring S-1A, and a profile of seismic wave velocities. The mean compressional and shear wave velocities, was well as the Poisson's ratio for various depth intervals between plant grade and the bottom of the S/L cluster boreholes (at a depth of 503 ft), are listed on Table 2.5.4-5F.

2.5.4.4.5 Ambient Vibration Measurement

Measurements of ground motion due to background (ambient) vibrations were made at each site when drilling rigs or other equipment were not operating.

The three-component VS-1200 Sprengnether Engineering seismograph was used to record ambient ground motions. This seismograph has gain characteristics of 20 inches per inch per second in the velocity mode, 12 inches per inch per second in the acceleration mode and 200 inches per inch in the displacement mode. A VS-1100 amplifier with a gain characteristic of 100 was used for all recordings. The resultant maximum gain level is 2,000 for the velocity mode, 1,200 for the acceleration mode and 20,000 for the displacement mode.

The three components of ground motion measured were radial, vertical and transverse. The seismometer was oriented facing either north or east. Table 2.5.4-5D presents the results of the ambient ground motion measurements.

2.5.4.4.6 Borehole Geophysical Logs

Gamma ray and resistivity surveys were made in preexcavation borings P-10, DI-2, DI-9, M-1 and DI-8A to aid in evaluating the correlating on-site stratigraphy. These boring locations are shown on Figures 2.5.5-5 and 2.5.5-6. The survey results are illustrated on Figures 2.5.4-22 through 2.5.4-26.

Gamma-ray, electrical resistivity, gamma-gamma, and caliper surveys were made in postconstruction boreholes S-1A, L-1, and L-2 as an aid to correlation of the borings and for refinement of the site stratigraphy. The gamma-gamma survey also provided a continuous record of in situ densities. The location of the borings are shown in Figures 2.5.4-14A and 2.5.5-5. The geophysical logs of these borings are almost identical due to closeness of the boreholes; the survey results are well represented by the logs of boreholes S-1A, which are shown in Figure 2.5.4-30A.

2.5.4.4.7 Interpretation of Geophysical Data

The refraction survey data indicated slight variations in the compressional wave velocity of the bedrock at the Station location. This variation in compressional wave velocities is most prevalent at shallow depth near the edges of the peninsula on which the Station is located.

The compressional wave velocities from the uphole velocity survey are different from the compressional wave velocities from the refraction survey. This is because a refraction survey develops an average compressional wave velocity over a large lateral distance, whereas the uphole velocity survey records the compressional wave velocity around the isolated point (i.e., the boring). It is felt that the compressional wave velocities obtained by the seismic refraction survey are a more appropriate measure of the actual dynamic properties of the site materials.

In the preexcavation stage of the site geophysical investigation, the geophysical surveys did not penetrate into the Twin Mountains Formation. However, indirect geophysical information from the surface and shear wave surveys indicates that both the compressional and shear wave velocities of the Twin Mountains Formation are lower than the corresponding velocities of the Glen Rose Formation. This was supported by the geologic borings which obtained basically 100 percent core recovery within the Glen Rose Formation and a much lower percentage recovery and Rock Quality Determination (RQD) in the underlying Twin Mountains Formation. The velocity inversion between the Glen Rose and Twin Mountains Formations was assumed to result in a seismic energy response characterized by the Glen Rose Formation acting as a seismic energy channel, or in essence, a plate of limestone. All these conclusions and assumptions have been

substantiated by the detailed postconstruction crosshole seismic survey that penetrated through the Twin Mountains Formation into the uppermost part of the underlying Mineral Wells Formation.

Surface waves at this site have unusual characteristics because of the seismic velocity inversion. The uppermost higher velocity Glen Rose Formation which acts as a plate or seismic channel, produces several discrete, but overlapping Rayleigh wave trains. These wave trains vary from 15 to 25 hertz, and from 5,000 to 2,500 feet per second (respectively) apparent velocity. The wave trains are essentially trapped waves within the plate of limestone and indicate an average shear wave velocity greater than 5,000 feet per second in the limestone. These waves are apparently second of higher mode vibrations within the plate. The maximum amplitudes and longest wave train have a frequency of 25 hertz. The maximum amplification of seismic energy, from an explosive source detonated at shallow depth is, therefore, at 25 hertz.

Some of the seismic records show a low-frequency wave train of about five to seven hertz. This wave is not well defined, but is probably the first mode Rayleigh wave vibration in the limestone plate.

The refraction and surface wave surveys are considered to give reasonably accurate data for the determination of compressional wave velocities while equally reliable data for the determination of the shear wave velocities was obtained by the Primacord technique. The surface wave surveys also produced a set of plausible values, with the initial crosshole surveys producing the least reliable set of values. However, the postconstruction crosshole survey produced more detailed measurements of both compressional and shear wave velocities. In comparision, the preexcavation geophysical explorations were not so detailed, systematic, and deeply penetrating. The postconstruction velocity measurements, together with the gamma-gamma log-derived densities, were the basis for the final design values of shear modulus and Poisson's ratio for the generalized profile (Table 2.5.4-5E). The initially selected values of the parameters based on the preexcavation geophysical surveys, are shown on Table 2.5.4-5. The dynamic rock properties based on both the preexcavation and postconstruction geophysical surveys are presented in Table 2.5.4-5H.

It should be noted that in the final determinations of compressional and shear wave velocities the information from all the techniques are integrated and used, with an understanding of the reliabilities, to produce the reported results.

2.5.4.5 Excavations and Backfill

The limits of required excavation for the power plant is shown on Figure 2.5.4-27. Figure 2.5.4-28 shows the location of the plant site and all cut and fill areas that occur adjacent to the plant site.

Figure 2.5.4-30 shows a 43-ft thick geologic section of the rock encountered in the excavations for Category I structures. This section is typical for the Category I portion of the power plant and related adjacent Category I support facility excavations. The limestone bed identified as bed "R" in Figure 2.5.4-30 is a reference bed in the plant site. The elevation of the top of bed "R" in Unit 1 reactor excavation was 782 feet 7 inches and 780 feet 9 inches in the Service Water Intake Structure excavation. This difference is due to the undulating nature of the beds and also because the Service Water Intake is downdip of Unit 1 Containment. Figure 2.5.4-30A is a general subsurface profile which includes a 500-ft thick geologic section of the materials constituting the foundation base of all plant structures.

Structural backfill was required on the north side of the Service Water Intake Structure. Figure 2.5.4-31 is a cross section of this area.

All Seismic Category I Electrical Duct Banks and the Service Water Pipe Trench require Category I backfill and bedding and are delineated in Figure 2.5.4-27. Figure 2.5.4-32 shows typical sections of the Service Water Pipe Trench and a Seismic Category I Electrical Duct Bank.

Geologic sections and blast-fracture maps were constructed as each excavation was completed for Category I structures. Figures 2.5.4-33, 2.5.4-34 and 2.5.4-35 are the fracture maps developed for the Unit 1 Containment and reactor excavation. Figure 2.5.4-36 is the photo grid for photographs taken of the Unit I Containment and Reactor excavation walls and Figure 2.5.4-37 (21 sheets) are the photographs depicted in Figure 2.5.4-36.

Excavation methods consisted of blasting, utilizing the presplit, primacord method, or heavy equipment demolition tools where blasting was not an acceptable method. Removal of the broken rock was accomplished by heavy equipment.

Protection of the exposed rock against weathering was required due to the argillaceous nature of some of the limestone beds and the claystone beds which are present. The wall portion of the excavations was protected by the application of shotcrete. The floor portion was protected by a minimum three inch thick concrete seal slab.

No groundwater was encountered in the primary Glen Rose Limestone, and therefore only normal pumping equipment and procedures were required to remove storm runoff and concrete curing water which collected in the open excavations.

Upon completion of removal of material from an excavation, a preliminary inspection was performed by the site geologist. After the final cleanup, just prior to placement of shotcrete or seal slab, photographs were taken and blast fracture maps were developed by the site geologist. At the time the geologist approved an excavation, the QA/QC program became involved, assuring cleanliness prior to application, curing and testing of protective coatings, and the inspection of these protective coatings prior to being covered by structural concrete.

To measure the rebound of the foundation rock due to the excavation on the plant site, two extensometers were installed. Figure 2.5.4-28 shows the locations of the extensometers. Monitoring results are presented in section 2.5.4.13.

The primary source for Category I backfill material was on-site quarries which are shown on Figure 2.5.4-29. A limited quantity of Category I backfill was obtained from Bridgeport, Texas.

During the preliminary grading and excavation of the plant site area, down to elevation 810', a bed of very hard, tan, fossiliferous, crystalline limestone, was intersected at an elevation of 825'. This particular bed is present throughout the site area and an initial quarry site northwest of the plant (Pit “A”, Figure 2.5.4-29) was selected for sampling and testing. Material was quarried from Pit “A” and processed through the crusher plant on site, a sample pulled and graded to the proper gradation, and then subjected to cyclic laboratory testing to verify that the material met specification requirements. Also sampled for testing was the concrete agregate sand which is being used as a bedding material around the pipe in the Service Water Pipe Trench and under the Seismic Category I Electrical Manholes. A complete discussion of this testing is covered in Section 2.5.4.7.

The compaction requirement for the backfill materials, placed against the Service Water Intake Structure, is a minimum of 95% of the maximum dry density as determined in accordance with AASHTO Designation T-99, Method D. In-place density was determined in accordance with ASTM D1556 (Sand Cone), ASTM D2167 (Balloon), or ASTM D3017 and D2922 (Nuclear). These density requirements apply to all Category I backfill material. Figure 2.5.4-38 shows the gradation requirements for the backfill material.

Based on the results of in-place density tests for Category I backfill, the following average backfill densities were obtained:

γDry = 130 pcf

γWet = 135 pcf

γSat = 140 pcf

The compaction requirement for the bedding material placed in both the Seismic Category I Electrical Duct Banks and Service Water Pipe Trench, is a minimum density of not less than 80% of the relative density as determined by ASTM Test Designation D2049, latest revision effective prior to September 4, 1975. In-place density was determined in accordance with ASTM D1556 (Sand Cone), ASTM D2167 (Balloon), or ASTM D2922 (Nuclear). Figure 2.5.4-38 shows the gradation requirements for the bedding material. The gradation, relative density, and percent compaction summaries are presented in Figures 2.5.4-44 thru 53.

Based on the results of in-place density tests for Category I bedding, the following average densities were obtained:

γDry = 120 pcf

γWet = 130 pcf

γSat = 135 pcf

2.5.4.6 Groundwater Conditions

A detailed description of groundwater is presented in Section 2.4.13. No groundwater was encountered during excavation for the plant foundation. Groundwater observations from piezometers installed at the site are provided on Figure 2.5.5-77.

2.5.4.7 Response of Soil to Dynamic Loading

The plant structures are founded on rock, however, granular material was required as backfill, pipe bedding and for the dam filters. The response of these materials to dynamic loading was assumed during the initial design phase. Later, an investigation of the actual dynamic strengths of these materials was performed by means of a cyclic triaxial testing program.

During design, adopted values for the cyclic shear strength for Category I backfill and bedding material were based on the published data for granular soils. A discussion of the published data is presented in Section 2.5.6.4.3.4. Since the D50 of the bedding material was approximately the same as for Filter “A” for the SSI Dam, the material was assumed to have essentially the same

cyclic shear strength characteristics. Category I backfill material has a D_{50} of approximately 15mm and since this material is coarser than the published data utilized, the cyclic shear strength characteristics of this material should be greater. For design, the cyclic shear strength criteria was assumed based on the data presented on Figure 2.5.6-48. The specific criteria was that the material with the gradation limits as shown on Figure 2.5.4-38 shall not allow development of double amplitude strain larger than 5% under specific corresponding stress conditions shown on Table No. 2.5.4-11.

In order to verify the adopted cyclic shear strength criteria for Category I bedding, backfill and filter materials, a test program utilizing cyclic triaxial tests was developed. A minimum of four cyclic triaxial tests were performed for each type of material utilized; one at each confining pressure as listed on Table 2.5.4-11. The applied stress given for the development of 5% double amplitude strain in five cycles was utilized since this stress is more critical than the stress combination specified for ten cycles of loading. Thus any specimen that developed 5% strain at ten cycles of load under a higher stress level automatically meets the criteria specified at ten cycles.

Four (4) different materials have been tested to determine if they meet the cyclic shear strength criteria as described above. The materials which have been tested are as follows:

Sample No.	Material
1	Filter A Material
2	ASTM C-33, Fine Aggregate
3	Glen Rose “Gray” Limestone Crushed Stone
4	Glen Rose Limestone “Crowder Quarry” Crushed Stone

The gradation limits of these materials, as well as the actual gradation curve of the tested materials, are shown are Figures 2.5.4-38A through 2.5.4-38D, respectively. The densities of the four (4) materials tested are summarized on Table 2.5.4-12.

For conventional laboratory triaxial testing of soils, it is generally recognized that the diameter of the test speciman should be at least six times the maximum particle size to avoid possible effects of sample geometry on test data. For Samples 3 and 4, the maximum size for the crushed stone was on the order of 2 inches, which would require triaxial cells capable of taking 12-inch test specimens. Such large cells, especially for dynamic testing, are not available for cyclic triaxial testing; therefore, modeling techniques have been utilized to model the field gradation of Samples 3 and 4.

One technique recommended by John Lowe [134] describes a technique of preparing a model soil with a grain size distribution curve parallel to the field material. Research on laboratory modeling of soils utilizing the parallel grading curve method has shown that the method can be used to predict the static and dynamic strength and deformation characteristics of soils. For Samples 3 and 4, a laboratory gradation range parallel to the field gradation requirements of the material has been drawn and an artificially blended material has been prepared (within these

limits) and utilized for the cyclic triaxial testing. (See Figures 2.5.4-38 C & D). For Samples 1 and 2, samples falling within the field gradation curves were obtained and were utilized for the cyclic triaxial testing. The test program followed guidelines set up in Report No. NUREG-31 entitled "Laboratory Triaxial Testing Procedures to Determine the Cyclic Strength of Soils", which was prepared under Contract No. NRC-E (11- 1) 2433 for the U.S. Nuclear Regulatory Commission.

The results of the initial tests are summarized in Table 2.5.4-13. One plot for each material tested at various confining pressures, relating double amplitude axial strain to the number of cycles of constant cyclic shear stress, are shown on Figures 2.5.4-39, Sheets 1 through 4. All of the materials tested were of sufficient strength to meet the cyclic strain criteria at 5 cycles of load. The ASTM C- 33, Fine Aggregate material (Sample 2) and the "Crowder Quarry" Crushed Stone (Sample 4) also met the strain criteria at 10 cycles of applied load. The Glen Rose Limestone Crushed Stone (Sample 3) met the strain criteria at 10 cycles for confining pressures of 2000 and 4000 pounds per square foot. However, the test results showed that the Glen Rose crushed limestone at 6000 and 8000 psf confining pressure, (Sample 3) and Filter "A" (Sample 1) did not meet the strain criteria in 10 cycles at the stress ratios utilized in the test program. Therefore, additional tests were run on Sample 1 and Sample 3 at reduced stress levels corresponding to stress ratios required to develop 5 percent strain in 10 cycles of load. The results of these tests are summarized in Table 2.5.4-13A.

For Sample 3, additional tests at reduced stress levels showed that the material did not meet the cyclic strain criteria at effective normal pressure of 6000 and 8000 psf in 10 cycles of load. The figures relating double amplitude strain to number of cycles for Sample 3 show that the cyclic strains were relatively low until about 6 to 8 cycles, after which large strains developed quite rapidly in only a few additional cycles and failure developed due to necking of the specimen.

For Sample 1, Filter "A" material, additional tests at reduced stress levels showed that the material did not meet the specification requirements at 10 cycles of loading. Utilizing all the test results for Filter "A" material, a liquefaction curve has been developed for Filter "A" material and is shown on Figure 2.5.1-6. From this liquefaction curve, a new curve has been developed relating the cyclic shear stress required to cause 5 percent strain to normal effective stress and is presented as Figure 2.5A-17.

The cyclic shear strength criteria of Filter "A" material for 10 cycles of load should be as follows:

Effective Normal Pressure Kips per Sq. Ft.	Cyclic Shear Stress Required to Cause 5×10^{-2} strain
0	0
2.0	0.90
4.0	1.60
6.0	2.20
8.0	2.80

In summary, the following points should be made:

1. Filter "A" material met the cyclic shear criteria for 5 cycles of load. The criteria for 10 cycles of load described in the previous paragraph has been adopted for design of pipe bedding material, where Filter "A" material is utilized in construction as a bedding material. How these results affect the stability of the SSI Dam is discussed in Appendix 2.5A.

2. ASTM C-33, Fine Aggregate met all of the cyclic shear strength criteria as shown in Table 2.5.4-11.

3. Glen Rose Limestone Crushed Stone met all the cyclic shear strength criteria as shown in Table 2.5.4-11 except at normal effective stresses of 6 and 8 KSF at 10 cycles of load. This material can be utilized as backfill material up to a confining pressure of 4 KSY (i.e., backfill to approximately 33 feet in depth.).

4. "Crowder Quarry" Crushed Stone met all the cyclic shear strength criteria as shown in Table 2.5.4-11.

The majority of Category I backfill has been "Crowder Quarry" crushed stone which meets all specifications for cyclic testing when compacted to the required density and the gradation of the materials meets the gradation requirements. Bedding material for Category I pipe has been ASTM C-33 fine aggregate sand which also meets all cyclic shear strength criteria. As stated previously the effect of the cyclic strength tests results on the stability of the SSI Dam are discussed in Appendix 2.5A.

In 1985 after the on-site sources of backfill material were no longer available, another source of material was investigated. Samples of crushed limestone from a quarry in Bridgeport, Texas were tested in order to determine their grain size, compaction and cyclic shear strength characteristics. The results of the test program are presented in Reference 144. Figure 2.5.4-57 shows the results of the cyclic strength testing program in terms of stress ratio versus number of cycles for 5% double amplitude strain. Four cyclic triaxial tests were performed on samples with a maximum grain size of 0.75-inch and a confining stress of 4000psf. At a stress ratio of 0.29, no significant strain developed; however, at a stress ratio of 0.42, 5% double amplitude strain developed in slightly less than 10 cycles. Figure 2.5.4-57 shows that the exact criteria for cyclic strength are not met for test #2; however, the test results are conservative since the in-place backfill contains grain sizes up to 2 inches. The conclusion presented in Reference 144 was that the material met the intent of the specification and was appropriate for use as Category I backfill.

2.5.4.8 Liquefaction Potential

The entire Nuclear Power Plant foundation consists of firm, unweathered, Glen Rose Limestone with no liquefaction susceptible soils present.

The cyclic shear strength of all Category I backfill and bedding materials used show that there is no liquefaction potential; all materials used meet or exceed the design criteria for cyclic strain for the ground acceleration of 0.12 g adopted for the Safe Shutdown Earthquake.

2.5.4.9 Earthquake Design Basis

A conservative Safe Shutdown Earthquake (SSE) having a peak horizontal ground acceleration at the top of bedrock of 0.12 g has been selected for design (Section 2.5.2.6). The Operating Basis Earthquake (OBE) is equal to 1/2 the SSE. Design response spectra and artificial time-history records are described in Section 3.7B.

2.5.4.10 Static Stability

2.5.4.10.1 Bearing Capacity

The major structures at the plant have been constructed on individual mat foundations (except individual spread footings under the Turbine Building columns) founded in the Glen Rose Limestone Formation. Properties of the limestone as well as the claystone material were determined and are presented in Section 2.5.4.2.

The ultimate bearing capacity of the Glen Rose Formation located under each structure has been determined from equations derived for local shear failure from the theory of elasticity [133] as follows:

q (ultimate) = (shear strength) (3.14)

The shear strength has been taken as one-half of the unconfined compressive strength. The above equation does not take into account the effects of overburden or the size of the foundation which would increase the safety factor against a bearing capacity failure. A study of the founding elevations indicated that some upper structures are founded on the claystone. However, when considering the anticipated pressure bulbs due to the applied loads, it is unrealistic to assume that claystone alone is subject to the applied stress. In fact, any shear failure occurring in the claystone zones would also have to pass through the thick underlying limestone layers.

From the results of the unconfined compression tests presented in Table 2.5.4-1, a reasonable average value of unconfined compressive strength for the claystone below elevation 810 is 40 ksf. This results in a very conservative value of 60 ksf for the ultimate bearing capacity of rock beneath Category I structures. The factor of safety against a local bearing capacity failure is the ultimate bearing capacity divided by the maximum foundation edge pressure. Table 2.5.4-6 summarizes the static bearing capacity factors of safety for the Category I structures. The safety factors against local shear failure exceed the minimum allowable of higher than the values presented in Table 2.5.4-6 due to the effects of embedment and foundation size.

The dynamic bearing capacity factors of safety were calculated for the maximum loads caused by the SSE. Table 2.5.4-6a presents the results of this analysis. The safety factors exceed the minimum allowable of 2.

The maximum edge pressure resulting from the overturning effects of earthquake or tornado loadings is 24.9 Kips per square foot under the Containment structure. The safety factor against overturning of the Containment is 2.0. It is calculated by taking moments about the lower edge of the foundation mat using the overturning forces generated by the safe shutdown earthquake. Vertical pressure distribution under the Containment during the SSE is shown in Figure 2.5.4-42.

2.5.4.10.2 Settlement of Foundations

The foundations of all structures in the plant area are founded on the Glen Rose formation. The removal of the overburden to elevation 810 resulted in a slight elastic rebound measured by extensometers to be 0.02 inches (Section 2.5.4.13). Due to the nature of the supporting rock and plant loads, a very small elastic settlement of the structures is anticipated. Time-dependent consolidation settlement of the claystone layers will not be considered due to the fact that these layers are heavily overconsolidated and are minor in proportion to the limestone over an approximate 200 feet thick depth of influence.

The settlements of the Category I structures were calculated using the theory of elasticity for a uniformly loaded area on an elastic half-space. The following equation [138] was utilized:

$$s = C_s \, p \, B\left(\frac{1-\nu^2}{E}\right)$$

where:

s = elastic settlement

C = shape and rigidity factor

p = uniform foundation pressure

B = width of rectangular footing or diameter of a circular footing

υ = static Poisson's ratio, 0.25

E = static elastic modulus, 4.8 x 105 psi.

The rock mass deformation modulus was estimated based on site seismic surveys (Table 2.5.4-5) with a correction for rock mass quality (RQD) [139]. The modulus was also checked using the results of moduli determined by laboratory methods (Table 2.5.4-4). Uncertainty of the effect of blasting and construction activities on the in-situ modulus was considered when evaluating an appropriate modulus for the use in the analysis. The modulus used for the settlement analysis was 4.8 x 105 psi.

A summary of the settlement of the Category I structures is presented in Table 2.5.4-7. The maximum predicted settlement is 0.26 inches at the center of the reactor containment. Since the settlement is elastic, it should occur immediately after final load application.

Expansive characteristics of the claystone were measured by conducting an absorption-pressure-swell test. The results of the test indicate that introduction of water to the sample could generate a pressure of 1140 pounds per square foot in the upward direction when swell is prevented. Therefore, is the applied load equals or exceeds this value, no swell should be anticipated. However, if the loads on the claystone layer are less than 1140 pounds per square foot, some swelling will take place. Figure 2.5.4-43 relates the total potential swell to the thickness of a claystone layer. The interpretation of this graph is shown by use of a hypothetical example on the same sheet. The small amount of swell calculated indicates no problems are anticipated due to the swell potential of the claystone.

During construction, additional samples of the claystone layers were obtained and tested to evaluate the swell potential of the claystone beneath Category I Pipe Structure.

The tests showed a maximum of free-swell of 3.0 percent and ranged from 0.7 to 3.0 percent. The maximum pressure to restrain swelling was 1940 pounds per square foot and ranged from 517 to 1940 pounds per square foot. These values are directly comparable with values reported during design (3.0 percent free-swell and 1875 pounds per square inch absorption pressure).

Along the alignment of the Category I Piping, an analysis shows the swell potential to be in the range of 0.01 inches, which is considered negligible. Therefore, in areas where intact rock has been exposed above the 15 foot line, the removal of claystone beds was not warranted. In areas where pre-splitting of the rock had already been carried down to the 15 foot depth, all fractured rock has been removed to reach the intact sound Glen Rose Limestone and Category I backfill material has been placed. Figure 2.5.4-37A is a plan view of the Surface Water Intake and Discharge pipe trench excavation showing the intact rock elevation along the alignment.

2.5.4.10.3 Lateral Forces

The magnitude and distribution of lateral earth pressures is a function of the allowable yielding of the wall, the backfill or rock characteristics, water pressure, surcharge loads from adjacent structures, and, for seismically designed structures, the earthquake loading. The concrete foundation walls were conservatively assumed to be rigid, unyielding walls. Therefore, the coefficient of earth pressure at rest, K_o, has been used in evaluating lateral soil pressures on these walls. A value of $K_o = 0.47$ was used based on an assumed friction angle of 32° for backfill at the site.

It was conservatively assumed that the groundwater table is at plant grade (elevation 810) except at the service water intake structure where plantside water level was taken as elevation 793. The actual groundwater level conditions have been verified by piezometric data (Section 2.5.4.13).

For structures cast against excavated rock, lateral pressure against the walls has been taken as:

$$\sigma h = \sigma v\left(\frac{v}{1-v}\right) = 0.33v$$

where:

σh = horizontal stress or pressure, psf

σv = vertical stress or pressure, psf

υ = Poisson's Ratio - 0.25

The vertical stress used for the individual structures should also include any surcharge load which exists.

This is an estimate of rock pressure which does not take into account the relative stiffness of the wall and the rock mass. In some cases, a more detailed evaluation of rock pressures based on the unique geological discontinuities was performed.

Dynamic loadings include pressures due to the soil or rock mass, water, and surcharge, accelerated in the vertical and horizontal directions. Figure 2.5.4-54 graphically depicts the static and dynamic lateral earth pressures.

The terms presented on Figure 2.5.4-54 are defined as follows:

γ_t = total unit weight of soil/rock (pcf)

γw = unit weight of water (pcf)

κ_o = coefficient of at-rest earth pressure

q = surcharge load

K_{AE} = seismic earth pressure coefficient

α_h = horizontal seismic coefficient

σ_c = compaction-induced earth pressure

These terms are more clearly defined in Reference 145, 146 and 147.

2.5.4.11 Design Criteria

Methods used to evaluate bearing capacity, settlement and lateral earth pressures are discussed in Section 2.5.4.10. Soil and rock properties used in the analyses are provided in Sections 2.5.4.4 and 2.5.4.5. The slope stability of the SSI and Squaw Creek dams is discussed in Section 2.5.6.

The minimum acceptable design factor of safety for bearing capacity is 3.0 under static loading conditions and 2.0 for dynamic conditions. The minimum allowable factor of safety for the SSI dam slope stability is 1.5 for static conditions and 1.1 for dynamic conditions.

2.5.4.12 Techniques to Improve Subsurface Conditions

No special techniques were required to improve foundation conditions except where blasting shattered or fractured the rock adjacent to or within the plant foundation.

In order to improve these areas of exception, dental concrete was used to replace fractured rock and to fill overexcavated areas. In areas where fractures not requiring removal were encountered, grout pipes were installed. Grouting operations are to be performed at the appropriate time, i.e., when the foundation affected was completed to the point that the grout was confined.

2.5.4.13 Subsurface Instrumentation

2.5.4.13.1 Extensometers

Two extensometers were installed in locations shown on Figure 2.5.4-28. Extensometers were installed during removal of common material from the plant site to measure the rebound of the foundation material and were monitored during the excavation phase of plant construction. At the end of the excavation phase the extensometers were terminated and the data evaluated. The measured rebound was 0.02 inches which is well within the anticipated amount of rebound.

2.5.4.13.2 Post-construction Groundwater Monitoring

A system of 17 piezometers has been installed in the plant area in order to monitor groundwater conditions. The location of the piezometers is shown in Fig. 2.5.4-55 and the typical piezometer detail is shown in Fig. 2.5.4-56.

Design of plant structures initially assumed groundwater at elevation 775 ft. (Section 2.4.13). Installation and observation of these piezometers has verified the actual groundwater condition at the site. The piezometer boreholes were completed as test borings, with continuous NX rock core and water pressure tests throughout the cored interval. Boring logs are presented in Figures 2.5.5-78 through 94. Upon completion of piezometer installation, groundwater data was collected for a period of one year to determine seasonal variations. The groundwater level was also correlated with weekly rainfall.

2.5.4.14 Construction Notes

Required excavation operations, including blasting, at times resulted in fracturing or shattering of the foundation rock adjacent to or within the plant foundation. Such excavation and subsequent backfilling with pervious material of the duct banks, piping, etc. throughout the plant site has changed the rock formation from an impervious material to a fractured and pervious material. The horizontal and vertical extent of the fractures and backfilling varies over the site.

Section 2.5.4.12 describes the treatment of shattered or fractured foundation rock.

Frequent changes in construction techniques were made in the early stages of excavation in the plant area. All such changes were within specification requirements, were made to reduce fracturing of rock, and included the following techniques:

1. Line drilling to isolate the proposed excavation area

2. Pre-splitting

3. Rock sawing (isolation)

4. Blast hole spacing

5. Amount and type of explosives

6. Time-delay of multiple blasts

No significant construction problems, other than rock fracturing, have been encountered.

During construction small volumes of water in-leakage at various structures was observed. The in-leakage problem exists at the turbine building and various Category I structures. This condition was solved at the turbine building by installing a permanent drainage system.

The in-leakage is caused by perched water collected at the foundation exteriors. The perched water source is mainly the result of surface water, such as rainfall runoff or construction and maintenance runoff. The water migrates to the foundation exterior surfaces through the utility trenches, filled with permeable bedding and backfill material, that intersect the structures.

Seventeen piezometers (Section 2.5.4.13.2) have been installed at the locations shown in Figure 2.5.4-55 and were monitored for a period of one year. The perched water condition around the plant structures has been evaluated and no remedial actions were necessary.

2.5.5 STABILITY OF SLOPES

2.5.5.1 Slope Characteristics

There are no slopes, either natural or man-made, in the vicinity of the plant, whose failure could adversely effect the plant.

The existing slopes along the creek bed that form the reservoir behind the Safe Shutdown Impoundment Dam are comparatively gently slopes and are characterized by a very thin mantle of soil underlain by limestone of the Glen Rose Formation. In many areas, all soil cover has been eroded and the rock outcrops. The steepest slope present along the reservoir boundary occurs on the south side of the Safe Shutdown Impoundment and approximately 600 feet upstream from the axis of the SSI Dam (Figure 2.5.5-2). Current topographic data indicates that at this location, the ground elevation increases from elevation 750 to elevation 800 over a horizontal distance of approximately 150 feet, or a slope of approximately 3 horizontal to 1 vertical. All other slopes along the total impoundment shoreline are in the range of 4 horizontal to 1 vertical, or flatter.

Topography of a part of the reservoir in the plant site vicinity, shown on a 10 foot contour interval is presented on Figure 2.5.5-5 together with the location of Sections Numbered 1-1, 2-2, 3-3, and 4- 4. These sections include the steepest slope condition along the shoreline of the SSI reservoir.

Subsurface profiles at each location were obtained by trench excavation. A wedge-type stability analysis using moist, saturated and submerged unit weights, appropriate strength properties for the materials present, and a seismic coefficient of 0.12 g was made for Sections 1-1, 2-2, 3-3 and 4-4. The results indicate a minimum safety factor against a slope slide of greater than 3. The Sections, including the results of the wedge-type stability analysis, are shown on Figures 2.5.5-1, 2.5.5-2, 2.5.5-3, and 2.5.5-4.

Some degree of weathering of the rock outcrops has occurred, and if one assumes that the weathering has extended to such a degree as to be the equivalent of a granular material with a 0 angle of 35 degrees, the existing slope will have a safety factor against a shallow near- surface slide greater than 2.0, a value considered entirely adequate. Any slide deeper than that of the weathered rock will have a larger safety factor.

2.5.5.2 Design Criteria and Analyses

The method of dynamic analysis of the SSI Dam is described in Section 3.7B.2.13 and the details of the analysis are presented in Section 2.5.6.5.

2.5.5.3 Log of Borings

The locations of borings made for the plant and dam explorations are shown in Figures 2.5.5-5 and 2.5.5-6. The logs of these borings are presented in Figures 2.5.5-7 through 2.5.5-76.

Borings were drilled with truck-mounted rotary-wash or auger drilling equipment. Overburden soil samples suitable for testing were obtained from some of the borings, and the underlying rock has been continuously cored utilizing standard NX coring equipment. The soils encountered have been classified in accordance with the Unified Soil Classification System. Geologic rock classifications have been based on macroscopic and hand lens examination of cores. Percent core recovery and R.Q.D. (Rock Quality Designation) information are presented on the boring logs.

The borings were drilled in the overburden soils by advancing a 3 or 4 inch diameter hole to the desired sampling depth. Undisturbed soil samples were obtained by hydraulically pressing a 2-inch Shelby tube or a 2.5-inch diameter thinwall sampler. Some disturbed samples were obtained from the auger flight, and disturbed Standard Penetration Test samples were also taken.

Drilling mud and casing were used when necessary during the drilling of overburden soils. Prior to coring the underlying rock, each boring was flushed thoroughly with water.

Two-inch diameter plastic pipes were installed in several borings to enable observation of groundwater levels (Figure 2.5.5-5). Because the Glen Rose formation is essentially impermeable, water levels reach static equilibrium slowly. Therefore, observations were continued for an extended period to confirm static levels. The observations made in borings at Category I facilities are summarized in Figure 2.5.5-77.

The static water level in the Twin Mountains formation was observed in Boring P-10, one of two borings penetrating the stratum. The piezometric level is indicated to be Elevation 670.

2.5.5.4 Compacted Fill

A detailed discussion of the areas requiring fill and the sources of fill materials required is given in Section 2.5.4.5. The extent of these fill areas are shown on Figure 2.5.4-28.

2.5.6 EMBANKMENTS AND DAMS

2.5.6.1 General

2.5.6.1.1 Squaw Creek Dam

The purpose of Squaw Creek Dam (SCD) is to impound a cooling lake for CPNPP. The location and configuration of the reservoir are shown in Figures 2.5.6-1 and 2.4-1. Under normal operating conditions, the reservoir will remain in the five-ft range between a minimum operating

level at elevation 770.0 and the crest of the service spillway at elevation 775.0. Rainfall or pumping of makeup water can result in flow over the Service Spillway Crest.

The layout of Squaw Creek Dam is shown in Figure 2.4-16. A typical cross-section of the embankment is shown in Figure 2.4-17. The dam is designed to pass the Probable Maximum Flood with sufficient freeboard to prevent overtopping by wave action generated by a sustained 40 mph overland wind. The top of the dam is a elevation 796.0 with overbuild to elevation 798.4 to compensate for estimated settlement. The central section is constructed of select, impervious material, with a cutoff extending down to impervious foundation material. The outer zones of the embankment are of less select material with the outer portion of the downstream shell being rock fill. A filter system separates the impervious central zone from the less select outer zone on the downstream side and extends outward to the downstream toe to provide drainage and piping protection for the core.

The reservoir side of the dam is protected by rock riprap and a gravel blanket from the top of the embankment to elevation 760.0, which is 10.0 ft. below the minimum operating level. The top width of the embankment is 20 ft., exclusive of riprap and blanket. Design of the riprap was based on an average over-water wind of 95 mph.

The service spillway is an uncontrolled structure 100 ft wide, with an ogee crest at elevation 775.0 Additional discharge capacity for protection from extreme floods is provided by a broadcrest emergency spillway, 2,200 ft. wide, excavated in rock of the east abutment at elevation 783.0. The sides of the discharge channel from the stilling basin to Squaw Creek are protected with rock riprap and blanket. The floor of the channel is native limestone. A 12-inch makeup water pipeline and 36-inch diameter return pipeline crosses the emergency spillway along its crest. Both lines are placed in a trench cut in limestone and is covered with a concrete cap. The top of this cap is at elevation 783.0.

Service outlet facilities are located near the right abutment of the dam and consist of an intake tower and outlet conduit. The tower has a 6 ft. by 6 ft. control gate at its base leading to a 6 ft. diameter conduit through the dam that discharges to Squaw Creek. The tower has ports at various levels to allow selective taking of water from the reservoir. Backup closure facilities are provided to protect against loss of storage due to inability to close a valve or gate.

2.5.6.1.2 Safe Shutdown Impoundment Dam

A portion of the arm of the reservoir that is formed by the channel of Panther Branch is utilized as a Safe Shutdown Impoundment, which holds water for emergency cooling use. The secondary reservoir is separated from the main body of the reservoir by a rock fill dam. An open spillway channel was excavated through the narrow ridge to the southwest of the SSI Dam, to connect the SSI with the main body of the reservoir. The floor of the channel is at elevation 769.5, six in. below the normal minimum operating level, and water will pass back and forth to keep the large and small reservoir surfaces at the same elevation under normal operating conditions. If the level in the main reservoir should drop due to some emergency, the SSI Dam will hold back 367 acre-ft of reserve water to allow continued cooling and safe shutdown of the plant.

The location and layout of the SSI Dam are shown in Figures 2.5.6-1 and 2.4-23. Details of the SSI Dam embankment are shown in Figure 2.4-21. The middle zone is of select, impervious material, wetted and rolled, and carried down to impervious foundation material for effective cut-off. The outer zones are rock fill. Two-stage filters were placed between the core and the

rock fill sections. The embankment crest is 40 feet wide at elevation 796.0. The spillway channel is 40 feet wide, with side slopes of 1-on-3 and a channel slope of 0.003 upstream and downstream from a concrete wall approximately flush with the channel bottom.

The SSI Dam is designed to pass the Probable Maximum Flood with or without the presence of SCR, with sufficient freeboard to prevent overtopping by waves generated in either direction, i.e. from the SSI or SCR, by a sustained 40 mph overland wind.

The embankment is designed to be stable during the rapid drawdown caused by the sudden and total loss of the SCR.

Seismic Design Criteria for the SSI are discussed in Section 3.7.

The ability of the SSI to meet the criteria of Regulatory Guide 1.27 is discussed in Section 9.2.5.

2.5.6.2 Exploration

The subsurface investigation conducted for Squaw Creek Dam and SSI Dam during design consisted of the undisturbed sampling of alluvial overburden materials as well as the undisturbed sampling of the primary sediments present.

The cohesive soils present along the centerline of the dam site were sampled at vertical intervals of 5.0 ft or at a change in material type, whichever was the lesser distance. These samples of cohesive materials were obtained by means of a thin-walled, seamless, Shelby tube sampler forced into the soil by means of a rapid thrust from two balanced hydraulic rams. The samples were then field extracted, preserved in moisture-proof polyethylene plastic and sealed to prevent changes in moisture content and accompanying changes in physical characteristics, identified as to boring number and depth, and packaged for transport to the laboratory in Dallas, Texas, for further tests and analyses.

Primary sediments encountered were sampled continuously utilizing a double tube, bottom discharge, conventional coring tool fitted with an appropriate cutting bit, using water as a drilling fluid.

Field infiltration tests were conducted in selected zones of the alluvial material in order to establish the permeability of the soil. In addition, pressure testing of the primary sediments was accomplished by the insertion of an expandable packer at the location selected while water pressure inside the boring, between the packer and the bottom of the boring, was regulated by a water pump at the ground surface. The depth of the tests pressure in pounds per square in., and the quantity of water consumed during the tests are recorded, where applicable, on the individual field boring logs, and are summarized on Table 2.5.6-1. In addition, selected samples of primary sediments penetrated at the site were preserved in polyethylene plastic, in the manner described above, and all samples were transferred to the laboratory for further evaluation and tests.

Detailed descriptions of materials penetrated as well as all field testing conducted in conjunction with this investigative program are shown, where appropriate, on the boring logs which are discussed in Section 2.5.5.3.

2.5.6.2.1 Squaw Creek Dam

A series of NX-size vertical core borings were drilled in connection with the exploration for the foundations of the Squaw Creek Dam and appurtenances. Figure 2.5.5-6 shows the location of core borings in relationship to the centerline of the dam.

Borings identified as the D-I series and the D-II series, a total of 28 NX-size core borings, represent the foundation exploration along the centerline of the dam. A total of nine NX-size core borings, identified as Series ES borings, have been utilized to explore the emergency spillway location. Borings identified as SO-1 through SO-11 were drilled for the purpose of exploring two potential alignments for the service outlet works to be located in the valley section of the proposed construction. The service spillway, located on the right abutment of the proposed dam site, has been explored by a series of 16 NX-size core borings numbered SS-1 through SS-16. Additional foundation data was obtained through the drilling for two, four-inch diameter core borings located within the proposed spillway and identified herein as Borings Numbered SS-17 and SS-18.

In addition, further investigation of the service spillway area was accomplished by means of four NX-size, inclined, core borings drilled at the locations shown on the Figure 2.5.5-6 and identified as core borings numbered SSA-1 through SSA-4.

Geologic Profiles representing cross-sections along the Embankment Centerline, the Service Outlet Works, and the Service Spillway are shown on Figure 2.5.6-7 through 2.5.6-9, respectively.

2.5.6.2.2 Safe Shutdown Impoundment Dam (SSI Dam)

A series of NX-size vertical and angle core borings were drilled in connection with the exploration for the foundation of the SSI Dam, the equalization channel and rock excavation areas. Figure 2.5.5-5 shows the location of the core borings in relation to the centerline of the dam and equalization channel.

Borings identified as the M Series, a total of ten NX-size core borings, represent the foundation excavation along the alignment of the SSI Dam. Borings MS-7 and MS-8 are vertical, NX-sized core borings drilled in the equalization channel area. Borings BA-1 and 2 are angle borings drilled in the balancing channel area.

A geological profile along the centerline of the SSI Dam is presented in Figure 2.5.6-10. A geological section was developed for the equalization channel using the information from MS-7 and 8 and BA-1 and 2. This geological section is shown on Figure 2.5.6-11.

2.5.6.2.3 Borrow Material

Several potential borrow areas were explored and evaluated for use as potential impervious core and random fill material for Squaw Creek Dam and SSI Dam. Figure 2.5.4-29 shows the approximate locations of the different borrow areas investigated. Each of the borrow areas was investigated by a series of six-inch diameter continuous-flight auger borings or excavated pits. Laboratory analysis and engineering evaluation have been conducted on the materials lifted from the auger borings in order to develop design parameters utilizing such materials. Additional core

borings with field testing were drilled during construction in the area of the Service Water Outlet alignment and in the West Abutment to help verify depths to competent rock.

2.5.6.3 Foundation and Abutment Treatment

2.5.6.3.1 Squaw Creek Dam

Squaw Creek Dam is an earth and rockfill embankment structure founded on existing valley alluvium. To minimize leakage through the foundation, a core trench was excavated through the alluvium and weathered rock to impervious unweathered limestone and claystone. This core trench extends well into the abutments. Figure 2.5.6-2 is a profile of the completed excavation.

All transverse cracks were removed by excavation or intersected by a keyway trench, except in the vicinity of the service outlet where removal would undermine the structure. Here a rock saw was employed to cut an 11-in.-wide trench across the cracks to the depth of the crack. The trench was then backfilled with dental concrete. Water was encountered in vertical cracks exposed in the keyway trench, especially on the right side of the creek and at the horizontal contact of the alluvium and limestone. This water could cause the exposed claystone seams to weather rapidly causing overhangs of the limestone layer above the seams. To prevent this weathering, pneumatically placed concrete (shotcrete) was used to seal the claystone seams. The inflow of water from the vertical cracks was controlled by inserting a steel pipe at the base of the crack and then sealing the crack with shotcrete. When the shotcrete had gained strength and it was desired to begin backfill, the pipes were sealed with wood plugs. Potholes and overhangs were filled with dental concrete. Dental concrete and shotcrete were used to cover rough rock surfaces to provide a smooth surface to place backfill against. Figure 2.5.6-5C(1) is a photograph showing shotcreting activities.

Prior to excavation, the foundation for the random fill and rockfill zones of the embankment was cleared and grubbed of trees and roots and then stripped to rock or a maximum depth of 9 in. to remove topsoil, rubbish and vegetation. The foundations for the service spillway an service outlet structures were then excavated to solid limestone.

Claystone seams were sealed with a coating of shotcrete. Over excavation was corrected with 1500 psi concrete. Anchor bars were installed as required and the foundation drains were drilled after placement of the structural concrete. Water encountered in the excavation of the foundation for the service outlet intake tower was controlled by sumping and pumping.

The effectiveness of the cutoff trench was judged visually. Mason- Johnston & Associates, Inc., Geotechnical Consultants, determined when the weathered zone had been penetrated. The effectiveness of the saw cutoff trench was tested by observing the depth of the crack and, in some cases, the stoppage of the flow of water.

Weathered material extended to a greater depth in the right abutment than anticipated, causing the cutoff trench to be extended some 250 ft. into this abutment. The trench was terminated prior to reaching the service spillway. The water tightness of the formation between the service spillway structure and the termination of the deep core trench was verified by drilling both vertical and horizontal holes and pressure testing. These hole were filled with grout.

Construction procedures used for the foundation and abutment treatment were as follows:

Soil material was removed by scrapers.

Limestone and claystone were removed by blasting which was prededed by pre-splitting the limits of the excavation. Spacing and loading of the blast holes were adjusted as conditions dictated. Blasted material was removed by front end loaders and end dump trucks. Final shaping of the excavation was accomplished with demolition tools and hand-operated pavement breakers.

Dental concrete had a 28 day design strength of 3000 psi. The concrete was centrally batched and placed in accordance with the procedures of Section 8, ACI 301-72.

The pneumatically-placed concrete was a wet pre-mixed mixture conveyed by air slugs through a flexible tube and deposited in place by air pressure. The material had a minimum 7 day strength of 2400 psi and a minimum 28 day strength of 3000 psi.

All excavations were pumped dry, cleaned with high velocity jets of air and/or water and inspected prior to backfill.

Estimates of the construction quantities involved are included in Section 2.5.6.9.1.

2.5.6.3.2 Safe Shutdown Impoundment Dam

Safe Shutdown Impoundment Dam is a rockfill dam with an impervious earth core. The entire foundation was excavated to unweathered limestone to provide suitable support for the rockfill shells and to provide an impervious base for the core. (The term unweathered is interpreted with respect to engineering properties and not in a purely geological sense.) Figure 2.5.6-3 is a profile of the completed excavation.

All transverse cracks under the core zone were removed by excavation or sealed by making a 10-in.-wide saw cut across the crack for its full depth and backfilling with dental concrete. Some seepage was encountered on the upstream side of the excavation in rock strata above the foundation base. Pneumatically placed concrete (shotcrete) was used to seal claystone seams to prevent weathering and possible overhangs. This shotcrete was removed just prior to placement of core and filter material in their respective zones.

The abutments against which the core material would be place were cut to a slope not steeper than one on one in order to provide “wedging” as the core consolidated, thus increasing the watertightness of the contact between core and abutment. Vertical faces not in excess of 30 in. (the largest size rock in rockfill) were allowed under the rockfill zone. Verticals in excess of 30 in. were brought to a slope of one on one with fill concrete. Potholes were leveled with dental concrete.

The spillway is an open cut channel between SCR and the SSI. This channel was bottomed on limestone. The crest elevation is maintained by a concrete wall across the channel that is excavated into the limestone foundation.

The effectiveness of the impervious cutoff was further assured by excavating a trench 2 ft. wide, and ranging in depth form 6 to 8 ft., across the base of the foundation on the centerline of the dam. This trench was visually inspected by the Mason-Johnston Geotechnical Consultant to assure that all cracks had been intercepted prior to its backfill with dental concrete. All

excavation to unweathered limestone was accepted by the Engineering Geologist prior to covering with shotcrete, dental or fill concrete. Upon completion of all excavation, the entire foundation was jointly inspected and accepted by the Freese and Nichols Project Engineer and the Mason-Johnston Project Geotechnical Consultant.

Construction procedures used for the foundation and abutment treatment were the same as described for the SCD in Section 2.5.6.3.1. Estimates of the construction quantities involved are included in Section 2.5.6.9.2.

2.5.6.4 Embankment

2.5.6.4.1 Squaw Creek Dam

A typical cross-section of Squaw Creek Dam is shown on Figure 2.4-17. The top of the dam is at elevation 796.0. The central core is constructed of select, impervious material wetted and rolled, with a cutoff trench extending down into the impervious rock foundation material. The outer zone of the embankment are of a less select material with the outer zone of the downstream side being a rock fill. The filter system separates the impervious central zone from the less select outer zone on the downstream side and extends outward to the downstream toe to provide drainage and protection of the core.

The upstream side of the dam is protected by riprap and gravel blanket from the top of the embankment to elevation 760.0, which is ten feet below the minimum operating level. The crest width of the embankment is twenty feet.

The sides slopes of the dam as shown on Figure 2.5.1-7 are three horizontal to one vertical on the downstream slope and two horizontal to one vertical to elevation 775 on the upstream slope and below 775 a three horizontal to one vertical slope. An upstream berm is located at elevation 760.0.

2.5.6.4.2 Safe Shutdown Impoundment Dam

A typical section of the SSI Dam is shown on Figure 2.4-21. The middle zone of the SSI Dam is composed of select impervious material, wetted and rolled, and carried down to the underlying firm, unweathered Glen Rose Limestone Formation. The outer zones of the SSI Dam consist entirely of the firm Glen Rose Limestone selectively quarried and processed to remove all claystone particles from the rock shell. The two zones of the SSI Dam are separated by two-stage filters. All components of the SSI embankment extend vertically downward to contact with the firm, unweathered, Glen Rose Limestone.

There are many aspects of the design construction procedure of this Class I Dam which make it much more conservative than most other existing dams. Primarily, these consist of the following:

1. The outside slope of the SSI Dam is flatter than slopes commonly used for a fill rock dam. Dams considerably higher than the SSI have been constructed in more seismically active areas with outside slopes in the range of 1.75 horizontal to 1 vertical.

2. The rock shell fill of the SSI Dam was placed in layers and compacted with multiple passes of a vibratory 10 ton roller. This compaction of the fill rock will provide a material with great strength and low compressibility.

3. The foundation of the entire SSI embankment is supported by the firm, unweathered Glen Rose Limestone.

4. The crest width of the dam (elevation 796) is 40 ft., which is considerably greater than most existing dams of 70 ft. height.

5. The width of the core at normal water surface is 20 feet.

6. The core material, while considered practically impervious, is not highly plastic. (CL in the Unified Soil Classification System).

7. Two stage filter, both upstream and downstream of the core, are present to control seepage, prevent piping, and control the effects of any cracks that may develop during the occurrence of the SSE.

A comparison of the SSI Dam with other existing fill rock dams in areas much more seismically active than the CPNPP site is presented in Table 2.5.6-2. Each of the dams in Table 2.5.6-2 has been constructed with slopes, both upstream and downstream, steeper than those for the SSI Dam at the CPNPP Project and constructed in a much more seismically active area. In summary, this SSI Dam is considered most conservative in design and construction and is conservatively appropriate for its intended purpose of providing a reservoir to function as the Ultimate Heat Sink during SSE conditions.

2.5.6.4.3 Material Properties Used for Design

A discussion of the laboratory procedures and tests used for adoption of both static and dynamic material properties for the rock shell, filter and clay core materials is included in the following subsections.

1. Shell Material

The laboratory modeling technique used during design for shell material consisted of the following sequential steps:

a. A probable range of gradations resulting from drilling, blasting, loading, placing, and compacting of the Glen Rose Limestone was estimated from prior experience, taking into account the known gradation of core material. The limits of probable design gradation of the shell material are shown on Figure 2.5.6-12.

b. Laboratory model techniques were used to obtain engineering properties of the rockfill. Actual NX (2 1/8" diameter) cores of the limestone from the plant site exploration borings, including a statistical average amount of claystone seams, were crushed in the laboratory to conform to the estimated gradation on a fraction-by- fraction basis; i. e., ultimate 10 inch diameter stones were reduced in the laboratory to particles 3 mm in diameter; one-quarter inch particles were reduced to 0.2 mm particles, etc. The gradation curve of the shell gradation model is shown on Figure 2.5.6-13.

c. The material representing the shell was then remolded, placed in a triaxial chamber, and a multi-stage “Q” test was conducted. The Mohr Diagram obtained

from this type of test is shown as Figure 2.5.6-14. Engineering properties of the shell material utilized for design purpose, are as follows:

Cohesion = 0

$\varphi = 37°$

Tan $\varphi = 0.754$

Unit Dry/Moist Weight = 115 pcf

Unit Saturated Weight = 135 pcf

2. Core Material

Borrow areas upstream of Squaw Creek Dam and downstream from the SSI Dam were investigated as potential borrow to form the impervious clay core of the two dams. Materials available for use in the core are CL in classification (Unified Soil Classification System) and have Liquid Limits ranging from 31 to 44 percent, Plastic indices ranging from 11 to 22, and Specific Gravities ranging from 2.65 to 2.70. Strength properties were determined on remolded materials prepared at moisture contents ranging from one percent below optimum to 3 percent above optimum and at density ranges equal to approximately 95 percent of the maximum density by the Standard AASHO Compaction Procedure.

Strength properties were determined by means of the Direct Shear test, where the rate of strain was computed to avoid a build-up of pore pressure and by triaxial testing in the form of Q test and R tests where complete saturation was obtained using back pressure and where pore pressures were measured.

Settlement and drainage characteristics of the impervious clay core were estimated from data obtained during consolidation testing with the coefficient of permeability, in the range of 10^{-8} centimeters per second, being computed from consolidation characteristics.

Typical results of laboratory tests conducted during design analysis of the material that has been used in the clay core of the SSI Dam are represented by Figures 2.5.6-15 through 2.5.6-17.

Cyclic strength determinations were not an important consideration in the dynamic analysis as explained in Section 2.5.6.5.2.

Based on a detailed analysis of the clay material, the following properties have been adopted for design of the core material:

Liquid Limit = 30-40%

Plasticity Index = 12-20

Optimum Moisture = 12%

Embankment Unit Dry Weight = 108 pcf

Embankment Unit Saturated Weight = 128 pcf

Strength Properties, Considolidated-Undrained (CU) Cohesion = 432 psf

$\varphi = 18°$

Tan $\varphi = 0.325$

3. Filter Zones

Materials that were used to form the upstream and downstream filters, separating the core from the shell, conformed to the gradation requirement of both the shell and core materials and was obtained offsite from Brazos River alluvial deposits. A two stage filter system has been utilized with the gradation limits of each zone shown on Figure 2.5.6-12.

4. Dynamic Strength Properties of the Filters and Rock Shell

For design purposes the seismic shear strength of the filter materials and rock shell for the dam has been estimated based on published data for granular soil, field embankment tests, and adopted criteria for construction. Factors considered in the assessment of the seismic strength characteristics included; (a) relative density; (b) grain size; (c) gradation; and (d) effect of initial static shear stresses.

Published data on the effect of relative density on seismic strength of filter materials have shown an increase in strength with increase in relative density. Based on this data, a relative density of at least 80 percent has been specified for the filters.

The effect of mean grain size on the cyclic shear strength of granular soils have been studied by Lee and Fitton [136], Seed and Peacock [137], and Wong (1970). The results of Lee and Fitton indicate a substantial increase in seismic strength as D_{50} increases from about 0.1 to 4 mm, and a very large increase in strength as D_{50} increases above 4 mm. The data presented by Seed and Peacock confirms Lee and Fitton's results. The results of Wong indicate only a slight increase in strength as the mean grain size increases from 0.6 to 10 mm, but a rapid increase in strength for mean grain sizes larger than 10mm.

The mean grain size of the fine filter is 0.6 mm (average) and the coarse filter 8.0 mm (average) as shown by Figure 2.5.6-12. Although the available published data would indicate a slight to substantial increase in strength as the mean grain size increases, this effect has been conservatively ignored in assessing the cyclic shear strength characteristics of the filter. Rather, the cyclic shear strength of the filter has been assessed on the basis of data for Sacramento River sand [135]. The data on this particular sand (a uniformly graded fine sand with $D_{50} = 0.2$ mm) has been utilized because of the comprehensive cyclic test data published, covering a wide range of confining pressures, relative densities, and seismic stress-strain levels.

Although the filter material is a well-graded material, whereas Sacramento River sand is a uniformly-graded sand, it is felt that little, if any, difference in the strength can be detected between well-graded and uniformly graded material for the same mean grain size. Research by Lee and-Fitton [136] confirm this conclusion. Wong (1970) tested a well-graded sandy gravel and found that the strengths were lower than uniformly graded gravels at low strains (approximately 5×10^{-2}); however, the well-graded gravels were more resistant to the development of large strain; in other words, 10×10^{-2}. Therefore, the published cyclic triaxial tests data for Sacramento River sand provide a reasonable basis for assessing the cyclic strength characteristics of the filters. Figure 2.5.6-48, prepared from this data, shows the cyclic shear stresses required to cause 5×10^{-2} strain in 5 and 10 cycles for filter materials compacted at a relative density of 80%.

The dynamic strength of the rock shell has been estimated in a similar manner as for the filters. Based on data by Wong (1970), the effect of mean grain sizes larger than 10 mm results in a rapid increase in cyclic strength. For a mean grain size of 100 mm, an increase in the cyclic strength of 83% may be expected and for a mean grain size of 152 mm at least 100% increase may be expected. The gradation of the rock in the actual test embankment had a mean grain size of 152 mm and the average of the rock shell in the actual dam is estimated to be no lower than 100 mm. Thus, the cyclic strength may be expected to be increased between 83% and 100%. To be conservative in analysis of the SSI Dam, the relationship shown in Figure 2.5.6-47 was derived. This figure presents the cyclic shear stresses required to cause 5×10^{-2} strain in 10 cycles for the compacted rock shell.

Initial static shear stress effects which occur in the filters and rock shell, and would result in an increase in material strength, have been ignored.

In developing the cyclic shear strength characteristics for design, it was assumed that pore pressures do not dissipate during earthquake motions. Because of the large particle size and high permeability of the rockfill, it is certain that any pore pressures would dissipate to some degree during the ground motions, and this would result in higher rock shell strengths than are being used in this analysis.

Lee and Fitton [136] found that clay materials have cyclic shear strengths greater than cyclic shear strengths for sands; however, the clay core of the SSI Dam has not been evaluated for cyclic shear strength but has been analyzed using the conservative assumption of liquefaction as described in Section 2.5.6.5.2.

During construction a test program was set up to evaluate the cyclic shear strengths of backfill material used at CPNPP to verify design assumptions. Included in the specimens tested were the fine filter material, Filter “A”. The details of the investigation are discussed in Section 2.5.4.7. How the results of Filter “A” tests affect the stability of the SSI Dam is discussed in Appendix 2.5A.

2.5.6.4.4 Rock Field Tests

A series of field tests for fill rock properties was conducted during design at the site of an abandoned quarry located at the CPNPP site. The location was selected to ensure that materials tested would be representative of those actually used in the construction of the SSI

Dam. Core borings were made at the proposed quarry site and a careful study was made of all cores to insure that the test quarry rock was representative of that which would be used in construction.

The primary objectives of the rock field tests included:

1. Determination of excavation procedures.

2. Evaluation of several wall-protection schemes.

3. Determination of compacted fill rock properties by construction and evaluation of the test embankment section.

Excavation operations at the quarry site consisted of the removal of all residual soils by the use of suitable-equipped crawler equipment, the drilling of blast holes to depths considered necessary to provide the desired quantity of materials, presplitting holes and blasting so as to provide a near vertical quarry face, and the removal of all excavated materials by loading equipment. The material was then transported to the test-embankment site and compacted in various layer thicknesses with various roller passes. The completed test-embankment was evaluated by means of a test trench. The test trench showed the presence of claystone particles. Since the test-embankment obtained with this type of quarry operation was considered totally unsuitable for high quality, pervious, rock fill section due to the presence of claystone particles, this source of material was abandoned.

Making full use of the results obtained from the first test quarry program, a new area immediately adjacent to the first area was prepared for excavation by removing all residual soils, drilling and shooting pre-splitting holes to establish a good quarry wall surface, then drilling and shooting blast holes on several patterns. Blast hole depths were controlled so as to bottom immediately above the elevation of known claystone layers. Shot hole patterns of 7 ft. by 7 ft. and 9 ft. by 9 ft. were used; in each case, holes were 3.5 in. in diameter. All holes were bottom loaded with DuPont Pour-vex, column loaded with HD-1 primer, and shot with primer cord. Water gel was used when some of the holes were noted to contain water.

Shot hole spacing, depths, and powder were varied to provide proper maximum size rock, well-graded rock with a minimum of spalls, and little or no claystone particles. With the controlled blasting operation, the limestone portion of the quarry rock was loaded out to the processing area and the remaining claystone areas and zones, readily identified, were removed by crawler equipment and wasted.

Quarried rock was processed by use of a vibrating grizzly and a vibrating screen; the size of openings in the vibrating screen were altered, as required, until material of a desired gradation was obtained.

The test embankment construction consisted of the following basic steps:

1. An area was selected for the test embankment and stripped of all overburden soil and weathered rock until a smooth, hard, and level unweathered Glen Rose Limestone surface was obtained. Corners of a 50 x 100 foot rectangle were marked.

2. Processed quarried rock was then hauled to the test embankment site, dumped, and smoothed to an approximately two-foot thick lift with a dozer. A ten-ton smooth wheel vibratory roller with the vibration mechanism disengaged was then allowed to make one pass to further smoother the surface of the lift. A grid pattern of approximately 10 by 7 ft. was established (21 points) on the surface of the rock layer and the elevation at each grid point determined and recorded.

3. Each layer was then compacted with a self-propelled vibratory roller weighing 10 tons and creating a dynamic force of 40,000 pounds, vibrating at 1400 cycles per minute, and having a drum diameter of 60 inches with a drum length of 104 inches. The elevation of the marked grid pattern points was determined after each pass of the vibratory roller; the number of passes varied up to six.

4. After the construction of the embankment was complete, a trench was excavated in the central portion of the test embankment and at right angles to the direction of roller passes to determine conditions of the embankment cross section.

Following the completion of the embankment, a designated area of the embankment was sluiced with water to visually determine the permeability and drainage characteristics of he rock fill and to provide an approximation of the moisture content retained in the fill.

Two large-scale density tests were made on the embankment in the following manner:

1. Following the placement of a particular lift and the application of a particular number of passes of a vibratory roller, a four-foot diameter steel ring was placed on the rock surface and secured in place by sand bags on the perimeter flange of the rings.

2. The rock material inside the ring and for a depth equal to the lift thickness, in the range of two feet, was hand excavated and saved for further use.

3. The excavation was lined with polyethylene film very loosely, including the bottom and sides.

4. Water levels from calibrated barrels were noted and water from these barrels was introduced into the polyethylene lines excavation until the level was within one in. of the steel ring.

5. The steel ring was then removed.

6. Additional water was added until the excavation was full; water levels in the calibrated barrel were noted and the volume of he excavation determined by the volume of water used.

7. The weight of the rock excavated was determined.

8. The “moist” density was determined by dividing the weight of the rock by the volume of the hole.

9. The rock from the excavation was “quartered”, piece-by-piece by hand, to obtain a smaller but representative sample and the moisture content was determined.

10. The “dry” density was then determined.

The results of all field observations and compaction tests, including grain size distribution, have been analyzed and are provided in Figure 2.5.6-18 through 2.5.6-24 and Table 2.5.6-8.

After removal of the desired quantity of rock from the test quarry, the existing floor was cleaned and the previously obtained vertical wall resulting from the pre-splitting operation was washed clean with a water nozzle. Shot crete panels were then constructed in order to produce a protecting surface against weathering on the vertical rock face. Two panels were selected; on the first panel a shot crete thickness of approximately one in. was constructed while on the second panel a surface approximately two in. in thickness was constructed. A seven sack cement mix was utilized in the construction of both panels.

Two shear tests were made in the field. The first shear test was run to determine the angle of internal friction between the rockfill embankment material and the in-place, firm, unweathered Glen Rose Limestone material. After determination of the friction angle between the rockfill embankment material and the underlying relatively smooth rock surface, a second direct shear test was made of the rockfill embankment material itself.

The shear box consisted of a reinforced, metal wall, six-ft cube, open on top and bottom, and separated on the bottom from the underlying relatively smooth limestone base by a system of small diameter rollers. Loads were applied to the box by means of a calibrated hydraulic ram acting through a suitable yoke arrangement and a ball-type joint. Deflections, or movements, were measured by means of dial micrometers placed at appropriate locations along the bottom and top edge of the shear box. Schematic details of the physical arrangement are illustrated on Figure 2.5.6-25.

Boulders larger than 12 in. in diameter were removed from the rockfill material so as to be compatible with the physical dimensions of the large scale shear box; all materials were weighed prior to placing in the shear box and then compacted with a “jumping jack” compactor to a density equivalent of that previously obtained from large scale density tests made after completion of the test embankment. The gravitational weight of the rock produced the normal force for four successive layer thicknesses.

The results of these tests are shown on Figures 2.5.6-21 and 2.5.6-22. The angle of sliding friction of rockfill material on in place limestone of approximately 42.9 degrees was determined as shown by Figure 2.5.6-23.

At the completion of the sliding resistance shear test, a strip of metal 4 in. in height was taken out of the shear box at about mid- height of the box and the hydraulic ram was removed so that the upper part of the box could be sheared (relative to the fixed lower portion of the box) to determine the angle of internal friction of the rockfill embankment material. The rock in the zone of the shear plane was limited to slightly less than 4 in. in size to correspond with the mechanics of the shear box. The results of these tests are shown on Figures 2.5.6-21 and 2.5.6-22 and indicate an angle of internal friction of 48 degrees.

Rockfill embankment material removed from the large scale field density test location was screened to determine the grain size distribution. The results of this determination are shown on

the attached Figure 2.5.6-24. The results of the field density test are shown in summary form on Table 2.5.6-3.

2.5.6.5 Slope Stability

2.5.6.5.1 Squaw Creek Dam

Embankment stability studies for the Squaw Creek Embankment have been made for the condition immediately after construction of the embankment but prior to the filling of the reservoir; and for a condition after construction with the reservoir present and a steady seepage condition established. In addition, an upstream reservoir drawdown case has been analyzed. Selected cases have been analyzed for static conditions and for a pseudo-dynamic condition wherein an acceleration of 0.12g is applied to the driving forces.

Appropriate soil strength parameters, described in detail in the following sub-sections, were used in embankment slope stability analysis. By means of the Swedish method of slices, a series of circular slides was analyzed until the minimum safety factor representing the critical slide surface was obtained. Full use of a computer program was made for this analysis. The computer program used for this analysis is described in Reference 134. After the location of the critical sliding surface was determined, hand computational methods were used to further evaluate the effects of pore pressure build-up during construction, steady seepage conditions, and the effect of an upstream reservoir drawdown. A series of wedge type analyses were made, by hand computational methods, to further determine the stability of the embankments under both static and pseudo-dynamic conditions. The results of these studies are shown on Figure 2.5.6-26. The safety factors presented on the table on Figure 2.5.6-26 are considered adequate and acceptable for the stability of the embankment under static loading conditions, wherein the minimum safety factor is 1.49, and under dynamic conditions, wherein the minimum safety factor is 1.04.

1. Strength Parameters

   The primary formation present at the site, as previously described, is that of the Glen Rose Limestone and strength and physical properties of these materials were evaluated by means of unconfined compression tests, Brazil Tensile Tests, and double ring shear tests.

   A portion of the embankment was constructed of rock obtained from required excavations on the site and this rock was quarried and run through a grizzly crusher so as to be well-graded, quarry run, with a maximum rock size limited to thirty inches in diameter. Strength and physical properties of this material were determined in the laboratory by a modeling technique. The modeling technique is described in Section 2.5.6.4.3. The strength properties of the impervious core and random fill material were determined by an evaluation of borrow material as described in Section 2.5.6.4.3.

   The design strength parameters of the various materials that will comprise the embankment section used in the slope stability analysis are as follows:

   Core:

γ = 117 pcf (95%-100% compaction)

C_u = 720 psf

φ_u = 15.5°

tan φ_u = 0.277

C = 2300 psf

φ = 16°

tan φ = 0.287

Random:

γ = 122 pcf (95%-100%)

C_u = 432 psf

φ_u = 19°

tan φ_u = 0.344

C = 2020 psf

φ = 19°

tan φ = 0.34

Rock:

γd = 115 pcf; $_s$= 135 pcf

$\overline{C}$ = 0

φ = 37.5°

tan φ = 0.767

Verification of design parameters is discussed in Appendix 2.5B.

2.5.6.5.2 Safe Shutdown Impoundment Dam (SSI Dam)

Stability of the SSI Dam was evaluated for operating conditions when the embankment and foundation are subject to ground motion from the SSE and when there is a total and instantaneous drawdown of the downstream side of the SSI Embankment resulting from the catastrophic loss of the Squaw Creek Dam. The dynamic response of the dam was determined by the procedure stated in Section 3.7.2.13. The details of the analysis are presented in the following subsections.

The static slope stability analysis of the embankment was performed and is shown on Figure 2.5.6-27. During the initial investigation, uniform upstream and downstream slope of 1.75 (horizontal) to 1 (vertical) and 2.5 (horizontal) to 1 (vertical) were evaluated.

The circular failure surface analysis utilized design strength properties given in Section 2.5.6.4.3. The failure surface which cuts through the core, filter and rock shell was found to provide a safety factor of 1.73 for the 1.75:1 slope condition. However, the most critical failure surface corresponds to a relatively shallow shear surface near the outer face of the shell where the safety factor was found to be 1.32. When the condition of rapid drawdown with negligible drainage of the rock slopes was considered, the safety factor was found to be 0.91.

Since the effects of the postulated seismic loading will be applied simultaneously to the condition of rapid drawdown, the result in outer slope stability would be reduced to a still lower value. The results of the stability studies, using design strength properties, for the uniform slope of 2.5:1 provided a safety factor of 2.43 for a critical sliding surface passing through the core, filter and rock shell. This factor decreased to 1.89 for a relatively shallow failure surface near the outer face of the rock shell. When rapid drawdown conditions were considered, again with negligible drainage of the shell, the safety factor was found to be 1.38. The effects of postulated seismic loading reduce the safety factors from those of static and total drawdown conditions; however, it appeared likely that the outer shell slopes in the range 2.5 to 1 would be adequate. The dynamic stability analysis was conducted utilizing the 2.5 to 1 slopes.

The liquefaction potential of the rock shell material and of the clay core material is considered practically non-existent; that of the filter zone materials is considered low. However, the effects of any possible liquefaction of the filter zone or core on the stability of the embankment has been analyzed by replacing the filter and core with a heavy liquid (static) and making a wedge type failure surface analysis where a seismic coefficient is applied. Filter zone gradation requirements are dependent on the gradation of the core material and shell material. The gradations for the rock shell material as well as the coarse and fine filters for the SSI Dam are shown on Figure 2.5.6-12. The properties of the impervious core filters and rock shell are discussed in Section 2.5.6.4.3.

1. Finite Element Model

   The structural integrity of the SSI Dam during the SSE was analyzed using a finite element method similar to that described by Clough and Chopra [135] and Chopra, Clough, Seed, et al. [136]. The finite element model consisted of a grid of 15 x 12 (180) nodal points (see Figure 2.5.6-28) connected in a regular fashion with 14 x 11 (154) quadrilateral elements. The general quadrilateral elements were formed by assembling the stiffness matrices of four constant triangles (CST). For the rockfill materials, the formulation of the stiffness matrix was the standard plain strain CST as described by Clough [137]. The mass matrix was formed by lumping one-quarter of the mass of each quadrilateral at the corner nodes in a manner consistent with Subsection 3.7.2.3. Static condensation was then used on the two center node displacements to reduce the element to 8 degrees of freedom. The clay core was modeled in a similar manner except that an additional hydrostatic variable was added to improve the accuracy in treating the nearly incompressible clay using the method described in Herrman [138]. The reformulated quadrilateral has two center node displacements and one pressure variable that are statically condensed to again give an 8 degree of freedom element. The clay core represents only a small portion of the cross-section and is modeled by the two central columns of elements in Figure 2.5.6-28.

2. Reservoir Dam Interaction

The hydrodynamic model of the SSI reservoir was accomplished using the added mass matrix described by Zienkiewicz [139] for the upstream and downstream faces of the SSI Dam. This model neglects the compressibility of the water but is a good approximation for dams below 100 feet in height [140]. The added mass coefficients were formed by solution of Laplace's equation in a semi-infinite plane reservoir and lead to a banded (non-diagonal) mass matrix. The added mass matrix coefficients are in the form of influence coefficients and decay rapidly away from the diagonal of the mass matrix. The band of the mass matrix was limited to 5 nodes.

3. Material Properties

The Shear moduli for the seismic analysis were based on the recommendations of Hardin & Drnevich [141], the results of the laboratory tests, the direct shear test, the average number of cycles expected during the duration of the SSE, and the average maximum shear strains predicted by the maximum spectral response for the lowest fundamental mode of vibration. The following properties were used:

ROCK FILL:

N	=	10 cycles
e	=	0.46 (void ratio)
γ	=	0.05 (Shear Strain)
γDRY	=	115 pcf
γSAT	=	135 pcf
ν	=	0.35 (Poisson's Ratio)
λavg.	=	0.08 (critical damping ratio)
G	=	45000 j psf

where is the effective vertical stress

CLAY CORE:

γDRY	=	115 pcf
ν	=	0.495 (Poisson's Ratio)
λavg.	=	0.08 (critical damping ratio)
G	=	500,000 psf

4. Natural Frequency and Loads of Vibration

The natural frequencies and nodes shape were determined using the subspace interaction procedure described in Bathe & Wison [142]. The first 10 natural frequencies were found to be in the range of 2.5 to 10 cycles per second.

5. Ground Motion History

An artificial ground motion history consistent with AEC Regulatory Guide 1.60 (revised) and the Newmark, Blume, and Kapur spectral envelope was used to perform both a step-by-step time motion history analysis and a spectral analysis of the seismic response of the SSI Dam. The artificial history was selected consistent with an anticipated structural damping of 8 percent. (The closest artificial history was for 7 percent structural damping). The 8 percent damping was determined from the elevation of the maximum shear strain together with the average vertical stress of a number of cycles using the Hardin & Drnevich formula.

The spectral envelope and artificial ground motion acceleration history are shown in Figures 3.7-4 and 3.7-9 for the horizontal component and Figures 3.7-18 and 3.7-23 for the vertical component. The ground motions were normalized so that the maximum horizontal acceleration was 0.12 g (at time = 3.52 seconds) and the maximum vertical acceleration was 0.08 g (at time = 3.44 seconds). It is important to note that although the peak vertical acceleration is 2/3 of the peak horizontal, as given by the Newmark, Blume, Kapur formula, it lies outside and is as severe as that for the horizontal component for all but the lowest fundamental frequency for the dam. Table 2.5.6-4 summarizes the Spectral Velocities for horizontal and vertical ground acceleration is 2/3 the horizontal, the maximum vertical accelerations in pseudo one degree of freedom systems of comparable frequency content of the dam are equal to the maximum horizontal accelerations. This is a very conservative modeling of an earthquake. A further comparison of the artificial acceleration history (Figure 3.7-9) with an actual 1925 earthquake at the site of Sheffield Dam [143] reveals that the artificial history has many more severe peaks (a > 0.05 g) than that of the Sheffield Earthquake.

The artificial time histories were developed and the dam analyzed for a duration of 10.24 seconds. Considering the very severe nature of the horizontal and vertical ground motion histories and since the number of cycles is not as significant a parameter for rockfill as for earth dams, this duration was deemed adequate for design purposes.

6. Step-By-Step Mode Superposition

Based on the natural frequencies and modes determined from the finite element model, a step-by-step mode superposition analysis was performed using the artificial histories for the combined horizontal and vertical components of the ground motion. The full 10.24 second duration was analyzed using a time increment of 0.01 seconds. The first 10 modes were analyzed using the Newmark generalized acceleration method. Figure 2.5.6-29 is a computer plot of the history of the acceleration of the nodal point at the downstream crest of the dam (“15-12”). The maximum acceleration of this node is 0.7 g and occurs at 5.85 seconds.

The response of the SSI Dam at times of 5.61 seconds, 5.70, 5.76, 5.85 (the maximum acceleration), and 5.91 seconds was selected for detailed study. At each of the stated time intervals, three drawings were prepared showing the nodal point acceleration vectors, the nodal point displacements, and the ratio of shear stress divided by the overburden stress. For time interval 5.61 seconds through 5.91 seconds, these relationships are shown on Figures 2.5.6-30 through 2.5.6-44, inclusive. The figures illustrating the acceleration vectors and the displacements at each nodal point and for each selected time interval also contain a vertical profile of acceleration or displacement from the top of the dam to the base of the dam along line 9.

Final displacements of the SSI Dam were estimated and have been plotted at a distorted scale to emphasize the permanent deflections and are shown on Figure 2.5.6-45. The procedure of determining permanent displacements consisted of the following:

a. Nodal point displacements were determined at the time of the maximum acceleration of nodal point “15-12”, the time of 5.85 seconds.

b. It was assumed that the artificial time history (Figure 2.5.6-29) for duration of 10.24 seconds may contain 15 peaks (all less than the maximum occurring at 5.85 seconds).

c. It was assumed that the number of such peaks over a 30 second time interval would be three times that occurring in the 10 second interval.

d. It was assumed that the computed displacements at each nodal point were in error by 100 percent and were multiplied by two (doubled).

Thus, the computed displacements at a time of 5.85 seconds were multiplied by a factor of 90 (15 times 3 times 2 = 90) to arrive at the final displacement configuration as shown on Figure 2.5.6-45. These displacements are considered extremely unlikely to actually occur in view of the pyramiding of the very conservative assumptions involved.

The procedure used in evaluating the seismic stability of the SSI Dam at local points and on horizontal planes consists of the following steps:

a. From the artificial ground motion study of the dam, the induced shear stresses at the various locations throughout the dam were evaluated.

b. The normal effective stresses at the various locations throughout the dam were determined.

c. Determinations of the cyclic shear stresses required to cause 5×10^{-2} strain were made at the various locations throughout the dam by use of Figures 2.5.6-47 and 2.5.6-48.

d. An evaluation was made of the ration of cyclic shear stresses required to cause 5×10^{-2} strain (f) with the shear stresses induced by the artificial ground motion,

The ratio, $\tau f/\tau d$ has been considered to represent a local factor of safety against the development of 5×10^{-2} strain. Figure 2.5.6-46 provides a graphic representation of the local factors of safety analyzed at Time=5.85 seconds (the time of the maximum acceleration). Table 2.5.6-5 presents the average of the local safety factors along the various horizontal planes. In this table, the average safety factors along horizontal planes decrease as the planes approach the crest elevation of the dam, as expected.

Local or point safety factors on or near the outer slopes near the crest of the dam have values less than one; these are not considered significant.

During construction, a test program to evaluate the cyclic shear strength of Class 1 backfill material was conducted. The results modified the curves on Figure 2.5.6-47 and Figure 2.5.6-48 as well as Figure 2.5.6-46. The effect of these changes on the stability of the SSI Dam are discussed in Appendix 2.5A.

7. Determination of Safety Factors

The evaluation of the effects of the SSE on the stability of the SSI rockfill dam has been made using two basic approaches. The first consisted of determining the dynamic response of the dam, the determination of the time of maximum acceleration, the magnitude of shear stresses at nodal points at this time, and the determination of the stress ration ($\tau d/\tau f$) or point safety factors. The details of this procedure are more fully described in Section 2.5.6.5.2.6.

The second procedure of determining the stability of the SSI rockfill dam during the conditions of the SSE consisted of a series of wedge analyses wherein the ultimate assumption was made that the core would liquefy, regardless of the value of acceleration, and would be resisted by the rock shell when the shell itself is subjected to the maximum value of acceleration as determined by the finite element procedure described in Section 2.5.6.5.2.6 for the time of 5.85 seconds.

The equation for determining the mean acceleration, a, for any distance, z, below the top of the dam, as related to the height of the dam (H) and the magnitude of the peak acceleration at the top of the dam (Ψ), was rigorously determined as:

$$\bar{a} = \Psi\left(1 - \frac{2z}{3H}\right)$$

The derivation of the equation is shown on Figure 2.5.6-49.

The equation of forces for a wedge type of analysis at any horizontal plane through the SSI rockfill shell when the shell itself was subjected to acceleration was rigorously derived and, in terms of safety factor, is expressed as:

$$F = \frac{\gamma r \cot\beta \tan\varphi}{K^{\gamma} r \cot\beta \tan\varphi + \gamma c}$$

The derivation of this equation is shown on Figure 2.5.6-50.

Thus, for any horizontal plane through the SSI rockfill dam at a depth z below the crest of the dam, the mean acceleration over the vertical distance H was determined using the maximum crest acceleration at T=5.85 seconds; this mean acceleration was redefined as k and the resulting safety factor determined for each of two cases. Case I represents the condition after loss of Squaw Creek Reservoir, with no tail water, and uses the saturated weight of rock shell material together with a angle of 37 degrees as determined on the laboratory model of the rock shell material, a value less than the field sliding resistance and direct shear tests which gave values in the range of 42 degrees. Case II represents a condition when Squaw Creek Reservoir

is present and the water surface on both sides of the SSI rockfill dam are equal at elevation 775 (normal water surface). Again, the angle of the rockfill shell remains as in Case I at 37 degrees.

Table 2.5.6-6 presents the safety factors resulting from this analysis for each horizontal plane. That table readily shows that the safety factor decreases as the plane analyzed approaches the crest of the dam which, of course, is the location of the greatest acceleration resulting from the occurrence of the SSE.

A comparison of the Safety Factor values obtained by the ultimate assumption of liquefaction of the core and wedge element analysis, as shown on Figure 2.5.6-51 show, without exception, that the core liquefaction and wedge analysis results in a lower safety factor than the average safety factor along the same horizontal plane in the finite element analysis. In both types of analyses, the safety factors along horizontal planes decrease as the planes approach the crest elevation of the dam, as expected.

In the case of the finite element analysis, Figure 2.5.6-46 shows local values less than one for points on the outer slope surfaces near the crest of the dam. These values result from the presence of little or no normal stress and are interpreted as meaning that, during the occurrence of the SSE, an occasional rock particle on the outer slope may be displaced enough to tumble or roll some short distance down the slope.

To further investigate this condition, a study was made to determine the magnitude of acceleration required to displace a rock lying adjacent to but not on the outer slope line. The details of this study are shown on Figure 2.5.6-52 and indicate that the acceleration must approach 4 g in magnitude for one rock to be displaced over another, an acceleration magnitude approximately six times greater than indicated to be present by the response of the dam to the artificial ground motion which, in itself, is considered most conservative.

Design verification of material properties and stability analysis are discussed in Appendix 2.5A.

2.5.6.6 Seepage Control

2.5.6.6.1 Squaw Creek Dam

Squaw Creek Dam is provided with a central impervious core extending to impervious foundation material. No seepage analysis was made since this core is considered to be a positive cutoff. The dam is provided with an 8 ft. wide sand filter, between the impervious core and the downstream random zone. The sand filter also extends horizontally with a thickness of 3 ft. between Stations 60+00 and 73+40. A 4-ft. wide vertical sand drain is located 370 ft from the centerline adjacent to the downstream toe of the dam between Stations 60+00 and 73+40. The sand drain penetrates the alluvium and bottoms on the foundation limestone, and is contiguous with the horizontal filter blanket. The entire drainage system exits at Squaw Creek where the volume of seepage may be observed. The purpose of the drain is to remove the possibility of a high phreatic level in the downstream random zone and to protect against piping of the core material in the event of its fracture. The vertical toe drain acts as a relief well for any hydrostatic pressures that may develop in the alluvial foundation. Material underlying the horizontal drainage blanket consists of existing in-place alluvial soils having a gradation essentially equal to that of the random zone. Immediately overlying the horizontal filter blanket is a 5 ft thick layer of random zone material.

The gradation of the filter is within the following limits:

Sieve Size	Percent Passing
1"	100
1/2"	65 - 100
1/4"	55 - 85
10 m	30 - 65
40 m	10 - 40
100 m	5 - 20
200 m	0 - 5

This gradation is designed to prevent piping of the core and random embankment zones. The design was developed using the procedures given in Reference [125].

2.5.6.6.2 Safe Shutdown Impoundment Dam

The Safe Shutdown Impoundment Dam is provided with a central impervious core founded on an impervious foundation. The shells are free-draining rockfill. No seepage analysis was made since the core is considered to be a positive cutoff. During normal operation there will be no differential head across the core.

Dual filters, each 5 ft thick, are provided on each side of the core between the core material and the rock fill shells. Filters on the downstream side are designed to prevent piping of the impervious material into the rock fill shell in the event of fracture of the core. Filters on the upstream side are designed to fill fractures in the core, should they occur. The gradations of the filter materials are based on design procedures in Reference [126] and are as follows:

Filter A

Sieve Size	Percent Passing
1/2"	100
4 m	78 - 100
10 m	50 - 85
40 m	33 - 60
100 m	8 - 27
200 m	0 - 10

Filter B

Sieve Size	Percent Passing
6"	100
3"	88 - 100
3/4"	60 - 78
4 m	32 - 45
10 m	15 - 26
40 m	0 - 10

Filter B is adjacent to the rock shells.

2.5.6.7 Diversion and Closure

2.5.6.7.1 Squaw Creek Dam

Squaw Creek is an intermittent stream. The U.S.G.S. gage “Squaw Creek near Glen Rose, Texas”, located on the State Highway 144 bridge approximately 2-1/2 miles downstream from the dam, showed in 1974 a maximum flow of 730 cfs and a minimum of 0.02 cfs. The average flow is 1.81 cfs.

The program for caring for water during construction was to leave an opening in the embankment until the remaining embankment and appurtenant structures were completed, then close the opening. This way, the natural flow of the stream would be passed on downstream.

The drawings required a 200 ft minimum opening in the embankment at elevation 655.0, centered on Squaw Creek. The maximum allowable side slopes of the embankment in this closure section were four (H) on one (V).

The core trench was completed on either side of Squaw Creek and the embankments were brought above natural ground prior to excavating the core trench across the creek. A cofferdam was constructed upstream and downstream of the excavation to stop the flow of the creek and to keep the excavation dry. The flow of the creek was pumped downstream from the cofferdams into Squaw Creek. Upon completion of the excavation and foundation treatment, the core trench was backfilled and the embankment was constructed to elevation 655.0.

During construction of the adjacent embankment and prior to closure, the normal flow of the creek was pumped over the embankment in the stream bed. Flood flows were passed over this embankment resulting in some embankment loss on several occasions. The lost embankment and any saturated embankment were replaced.

The closure of the embankment was not started until the following three items had been completed:

1. Embankment, including riprap and blanket, constructed to elevation 793.

2. Service spillway substantially compete including discharge channel with slope protection.

3. Service outlet complete except for gates and operators, but including service and emergency gate frames. The Service bridge was not complete.

Just prior to closure, all water impounded in Squaw Creek was drained through the service outlet by breaching the cofferdam in its inlet channel, and all undesirable materials were removed from the closure section. Closure was started on July 28, 1976, and was completed on May 14, 1977. Figure 2.5.6-5D(2) is a photograph of the SCD closure section.

Closure began by constructing the upstream random zone to elevation 673.0 to protect the downstream zones from flooding. Once this was accomplished, the filter blanket was placed and all zones of embankment brought to the same elevation. After completion of the filter blanket and placement of protective fill over it, a cofferdam was temporarily placed in the service outlet channel so that the service and emergency gates could be installed in their frames. The cofferdam was then removed to allow the flow of Squaw Creek to pass through the service outlet conduit.

The service outlet was closed and filling started on February 15, 1977. The following conditions were met prior to commencing impoundment:

1. Makeup Pump Station was operational.

2. Forty-eight in. portion of makeup pipeline was operational.

3. Embankment in the closure section was completed to at least elevation 729.

4. Service Spillway and Outlet Works construction was completed, including all mechanical and electrical activities and power supply to it.

5. SSI Dam was completed to an elevation which assured that SSI Dam construction would progress ahead of filling.

6. Rock shell and borrow material necessary for the remainder of the SSI Dam were stockpiled above elevation 775.

7. Riprap and bedding material for Squaw Creek Dam were stockpiled above elevation 775.

8. Flexible base material for dam roads was screened through a grizzly and stockpiled in an area accessible to the dam after the reservoir area was inundated.

9. Construction of the following structures was completed, or assurance established that construction could continue if the lake should fill:

   a. Circulating Water Intake Structure

   b. Circulating Water Discharge Structure

c. Service Water Intake Structure

d. Circulating Water Discharge Training Dike

Since the impoundment would make upstream borrow sources inaccessible, provisions were made for alternate downstream sources of material to complete the closure. Closure continued until the entire embankment was topped out.

2.5.6.7.2 Safe Shutdown Impoundment Dam

The flow in Panther Branch at the site of the SSI Dam is intermittent, like Squaw Creek, but subject to flood flows. It was not feasible to leave a closure section in the SSI Dam because the foundation excavation would be excavated 8 feet below the creek bottom, and it would be necessary to pump out this excavation after each flow. It was also believed that better construction quality would be obtained by constructing the entire length of this relatively short embankment level. Similarly, it was not desirable to allow flows to pass over completed embankment since material carried by the flows would contaminate the filters and possibly the rockfill zones. The dam does not have an outlet works through which Panther Branch could be diverted.

A cofferdam was constructed immediately upstream of the SSI Dam to contain the flow of the creek and to discharge the creek's flow through the interconnecting spillway channel into SCR below the SSI. This dam was constructed of alluvial material excavated from the floor of the SSI. It had a core trench to a impervious foundation which extended into each abutment as well as the valley floor. The side slopes were 3 (H) on 1 (V) and the 20-foot wide crown was at elevation 780-10.5 feet above the interconnecting spillway channel crest.

Drainage between the cofferdam and the SSI Dam foundation excavation was diverted to a pond and pumped over the cofferdam along with seepage and runoff trapped in the foundation excavation. All excavations were dewatered by sumping and pumping.

The cofferdam was lowered to elevation 755, then breached at three places when the SSI Dam was completed to elevation 780 and the Service Water Intake Structure was complete. Water was pumped over the cofferdam to equalize the SSI on either side of it prior to breaching.

2.5.6.8 Instrumentation

2.5.6.8.1 SSI Instrumentation

In order to verify the design parameters utilized and to evaluate the post-construction surface deformation, surface alignment and piezometric levels with in the SSI Dam, a system of permanent instrumentation has been installed as shown in Figure 2.5.6-53 and 2.5.6-54. The installed permanent instrumentation consists of surface movements, settlement plates to monitor internal vertical deformations, and wellpoint piezometers to monitor pore-water pressures within the embankment.

The settlement plates installed within the core of the SSI Dam are located as follows:

Station	Tip Elevation
6 + 50 C_L	770
8 + 50 C_L	770
10 + 50 C_L	770

Each settlement plate consists of a rectangular piece of steel conforming to ASTM A-36 of the following dimensions: 2.5'+ 0.25" X 2.5'+0.25" with a thickness of 1/2"+0.125". Each settlement plate was installed a minimum of one ft below the current working surface, at the time of installation, and backfilled and hand compacted in conformance with F&N specification SSI-1 (latest revision). All settlement plates were contractor-installed. At a later date if monitoring is needed, the settlement plates can be located using rotary core-drilling equipment. After the boring is advanced, a permanent observation casing can be installed, so that the settlement plates can be periodically probed in order to determine the interior movements taking place within the core of the SSI Dam.

Surface alignments monuments have been installed on the crest of the SSI Dam at the following locations:

No.	Station	Offset
SSI-SM-1	4+50	15.0' D.S.
SSI-SM-2	4+50	15.3' U.S.
SSI-SM-3	6+50	14.8' D.S.
SSI-SM-4	8+50	15.4' U.S.
SSI-SM-5	8+50	14.2' D.S.
SSI-SM-6	8+50	15.0' U.S.
SSI-SM-7	10+50	15.0' D.S.
SSI-SM-8	10+50	15.0' U.S.

All surface monuments were installed in accordance with MJA QAP-19. Installation of the surface monuments was accomplished by advancing a hole into the rockfill approximately 5 ft in depth. The hole was somewhat conical as it shown on Detail A of Figure 2.5.6-53. The surface monuments consisted of a No. 8 reinforcing bar approximately five ft in total length. The reinforcing bars were set into the bottom of the conical-shaped hole and encased in grout up to the approximate surface elevation. After the grout achieved a proper cure (28 days), the final elevations and offsets of the surface monuments were determined by the contractor in accordance with F&N SSI-1 Special Conditions, Item 9A and 9B (REV. 11).

The horizontal and vertical coordinates of the alignment monuments will be determined annually and compared with the original coordinates to determine the vertical and horizontal movements of the crest of the SSI Dam.

Wellpoint-type piezometers have been installed in the core of the SSI Dam at the following locations:

No.	Station	Tip Elevation
P-I-1	6+60 C	746.95'
P-I-2	6+70 C	766.71'
P-II-2	9+50 C	746.90'
P-II-2	9+60 C	767.03'

All piezometers have been installed in accordance with MJ QAP-18.

The wellpoint-type piezometers consist of industrially accepted stainless steel jacket wellpoints approximately 30" X 1.25"; a #60 mesh wire screen forms the outside of the wellpoint. Each wellpoint is coupled to a 1-in. standard galvanized riser pipe which extends from the tip elevation to the crest elevation. At the crest, the riser pipe has been fitted with a cap which is vented to allow pressure equalization.

Installation of the piezometers was accomplished by advancing an NX- size core boring down to a predetermined depth utilizing the rotary drilling process. After the boring was completed and bailed, the bottom portion of the boring was filled with approximately 1 ft of Ottawa sand. This sand formed a cushion for the wellpoint piezometer which was placed on the sand. After the wellpoint was seated, the sand column was extended around the wellpoint to approximately 3 ft above the screen. The remainder of the boring annular space, extending through the clay core of the dam, was filled to approximately elevation 786 with a dry bentonitic-type drilling additive. The final step in the installation process was the application of contractor-furnished grout through the remainder of the rockfill section up to the surface. The grout was formed into a conical shape at the surface to provide a positive anchor for the riser pipe. The uppermost part of the riser was recessed within this grout cone so as to be slightly below the existing crest elevation.

The piezometers installed in the SSI Dam will be monitored periodically during reservoir impoundment and operation in order to gain a measure of the piezometric level within the core of the dam.

The SSI dam will be inspected and piezometer readings taken annually. Results will be evaluated for significant or abnormal deviations from previously observed data trends. Unusual readings will be cause for increased surveillance of the SSI dam and determination and/or correction of the conditions which caused these readings.

2.5.6.8.2 Squaw Creek Dam Instrumentation

In order to verify design parameters, and to evaluate post construction surface deformations, alignments, piezometric levels and internal settlements within Squaw Creek Dam, the system of

permanent instrumentation as shown on the attached Figure 2.5.6-55 and 2.5.6-56 has been installed. Permanent instrumentation has consisted of surface alignment monuments to monitor the horizontal and vertical surface movements at the dam crest, settlement plates installed within the interior of the embankment core in order to monitor internal vertical deformations and wellpoint and pneumatic piezometers in order to monitor porewater pressures within the embankment section.

Surface monuments have been installed along the crest of Squaw Creek Dam at the following locations:

No.	Station	Offset	Elevation
SCD-SM-1	39+00	12.0' D.S.	796.7
SCD-SM-2	39+00	12.0' U.S.	796.8
SCD-SM-3	41+00	12.3' D.S.	796.6
SCD-SM-4	41+00	11.8' U.S.	797.0
SCD-SM-5	43+00	12.0' D.S.	796.9
SCD-SM-6	43+00	11.9' U.S.	797.1
SCD-SM-7	45+00	12.2' D.S.	797.0
SCD-SM-8	47+00	12.2' D.S.	797.3
SCD-SM-10	47+00	11.9' U.S.	797.8
SCD-SM-11	49+00	11.8' D.S.	798.3
SCD-SM-12	49+00	11.5' U.S.	798.5
SCD-SM-13	51+00	12.0' D.S.	798.5
SCD-SM-14	51+00	11.6' U.S.	799.0
SCD-SM-15	53+00	12.0' D.S.	798.6
SCD-SM-16	53+00	12.2' U.S.	799.3
SCD-SM-17	55+00	12.2' D.S.	798.5
SCD-SM-18	55+00	11.9' U.S.	799.3
SCD-SM-19	57+00	12.1' D.S.	798.7
SCD-SM-20	57+00	12.0' U.S.	798.2
SCD-SM-21	59+00	12.4' D.S.	798.3
SCD-SM-22	59+00	11.8' U.S.	799.0

No.	Station	Offset	Elevation
SCD-SM-23	61+00	12.2' D.S.	798.3
SCD-SM-24	61+00	11.9' U.S.	799.0
SCD-SM-25	63+00	12.1' D.S.	798.8
SCD-SM-26	63+00	12.2' U.S.	799.3
SCD-SM-27	65+00	11.7' D.S.	798.9
SCD-SM-28	65+00	11.7' U.S.	798.8
SCD-SM-29	67+00	12.9' D.S.	798.8
SCD-SM-30	67+00	11.9' U.S.	799.1
SCD-SM-31	69+00	12.2' D.S.	798.7
SCD-SM-32	69+00	12.2' U.S.	799.0
SCD-SM-33	71+00	12.4' D.S.	798.7
SCD-SM-34	71+00	11.6' U.S.	798.9
SCD-SM-35	73+00	12.3' D.S.	797.6
SCS-SM-36	73+00	12.2' U.S.	797.8
SCD-SM-37	75+00	12.1' D.S.	797.7
SCD-SM-38	75+00	11.9' U.S.	796.5

Installation of the surface monuments was accomplished in general accordance with MJ QAP-19. The installation procedure is similar to that described in Subsection 2.5.6.8.1.

The surface monuments installed on the crest of Squaw Creek Dam will be periodically observed for horizontal and vertical movements throughout the course of reservoir impoundment and operation.

Settlement place have been installed in the core of Squaw Creek Dam at the following locations:

Station	Offset	Elevation
50+49.2	0.6 Left of C	724.43
60+40.0	C	710.05
70+50.0	C	674.53

Each settlement plate consists of a rectangular piece of steel conforming to ASTM-A-36 with the following dimensions: 2.5' X 2.5' X 0.375'. Installation of the settlement plates was accomplished in the same general manner as that outlined in Subsection 2.5.6.8.1.

If settlement readings are desired, a core boring will be advanced to penetrate through the core of the dam down to the elevation of the settlement plates; and a permanent observation casing will be installed rising from the elevation of the settlement plate up to the crest of the dam. Utilizing the casing as access to the settlement plate, elevations could be taken periodically on the settlement plates and monitored to observe the internal vertical deformations.

Various combinations of wellpoint and pneumatic transducer piezometers have been installed in Squaw Creek Dam as shown on Table 2.5.6-7.

The piezometers were grouped in three ranges. Typically, each range of piezometers consists of a set of piezometers upstream of the centerline spread uniformly throughout the core of the dam, a set of piezometers downstream of the centerline spread uniformly throughout the core, and a set of piezometers near the toe of the dam with piezometers in the random section and in the alluvial section.

In order to facilitate the ongoing construction process, the piezometers contained within Range II were installed during the course of constructions. Two different types of piezometers were installed at Range II. Standard industrially-accepted stainless steel jacket wellpoint piezometers were installed at all locations for Range II. The wellpoints were nominally 30 inches in length by 1.25 inches and were encased by a No. 670 mesh screen. Additionally, companion pneumatic transducers were installed at the same elevation as the two deepest piezometers for each set (i.e., upstream, downstream, and near the toe). The pneumatic piezometer operates on a null balance principle whereby external pore pressure exerted on the transducer tip is exactly balanced b by an equal and opposite internal gas pressure supplied when reading the piezometer via an interconnecting tubing which connects the transducer to the surface readout station. By installing the pneumatic piezometers as companions to wellpoint piezometers at equal depths, their pore pressure readings may be compared to those obtained by the standard wellpoint type piezometers.

Similarly, wellpoint and pneumatic piezometers were installed near the toe of the dam at Station 46 and Station 69. The remainder of the piezometers, that is, the upstream (wellpoint) and near downstream (pneumatic) sets at Stations 46 and 69, were installed after completion of the Squaw Creek Dam.

The upstream set of piezometers for both Stations 46 and 69 were installed by drilling down through the completed crest of the dam. In order to avoid any disturbance to the finished grades on the downstream slope, it was impossible to install the downstream set of piezometers for Stations 46 and 49 by using vertical rotary drilling. Therefore, it as decided to install these piezometers by angle-core drilling from the existing completed crest of the dam down to the appropriate elevation and offset as previously determined. By using the angle-hole method of installation, standard wellpoint piezometers could not be utilized. Therefore, pneumatic transducers were installed for the near downstream sets at Stations 46 and 69. Even though the hole where the piezometers has been installed is drilled at an angle, the pore pressure reading at the tip elevation is in no way affected by the angularity of the hole.

The installation of the wellpoint piezometers in Squaw Creek Dam was essentially similar to that utilized for the SSI Dam as described in Paragraph 2.5.6.8.1, except that grout was not utilized to backfill the holes. Instead, the holes were filled with a bentonitic drilling additive. Installation of the pneumatic transducers was accomplished in a similar manner to that of the wellpoints. In this case, the riser pipe was utilized to protect the readout tubings leading from the pneumatic transducers to the ground surface.

Regular readings of the wellpoint and pneumatic piezometers are being made during impoundment and will continue during operation of the reservoir. These readings will be used to verify design parameters and to alert the geotechnical consultants to any extraordinary rise in pore pressure within the core of the dam or to any blockage of the filter on the downstream toe of the dam.

2.5.6.9 Construction Notes

2.5.6.9.1 Squaw Creek Dam

Estimated construction quantities for Squaw Creek Dam are as follows:

1.	Core Trench Excavation - Common	141,166 C.Y.
2.	Core Trench Excavation - Rock	137,488 C.Y.
3.	Emergency Spillway Excavation	1,205,165 C.Y.
4.	Service Outlet Excavation	104,282 C.Y.
5.	Service Spillway Excavation - Common	191,177 C.Y.
6.	Service Spillway Excavation - Rock	205,452 C.Y.
7.	Impervious Fill	1,138,935 C.Y.
8.	Random Fill	3,733,191 C.Y.
9.	Rock Fill	526,149 C.Y.
10.	Filter Sand	178,555 C.Y.
11.	Riprap	41,274 C.Y.
12.	Riprap Bedding	13,150 C.Y.

Figure 2.5.6-5A(1) is a photograph of the SCD site after stripping activities.

Construction of Squaw Creek Dam commenced on November 17,1 974, with the clearing and grubbing of the dam's foundation. Details of and problems encountered during the foundation and abutment excavation and treatment are discussed in Section 2.5.6.3.1. Figure 2.5.6-5B(1) shows a photograph of the foundation preparation activities. Soil material removed from the core trench was placed in the random embankment zones. Rock material excavated was wasted since it was generally too large for the rockfill zone.

On February 14, 1975, excavation of the east core trench was completed. The core trench was backfilled in section; that is, the east side of Squaw Creek was excavated to the abutment then backfilled. The same procedure was used on the west side of the creek which was completed on March 25, 1975. The excavation of the core trench in the closure section was completed on November 3, 1975.

Upon completing the backfill of the east core trench, placement of material in the east embankment began. As mentioned before, soil material excavated from the core had been placed in the random zone.

Select and random materials were obtained from upstream borrow pits. These pits were irrigated prior to use to bring the moisture content close to optimum. Rockfill material was obtained from the emergency spillway excavation. The east embankment was completed to elevation 791 on March 4, 1976, and the west embankment on July 19, 1976, when both embankments were brought to elevation 793. Figure 2.5.6-5A through Figure 2.5.6-5J are progress photographs of the construction of SCD.

Completion of the west embankment was delayed due to the time required to construct the service outlet conduit and backfill adjacent to it. Additional delay was encountered due to the need to extend the core excavation deep into the right abutment to unfractured material. The embankment could not be placed higher than the backfill in the abutment without forming a pocket that would pond water.

The specifications required that the select zone have a minimum liquid limit of 35. This requirement was relaxed to a minimum of 30 for fill placed above elevation 780 due to a shortage of material with a higher liquid limit.

It was originally planned to place all material excavated from the emergency spillway in the rock zone of the embankment. However, more random material containing weathered rock was encountered in the emergency spillway than anticipated. This material contained too much rock to be used as random fill and too much soil to be used as rockfill. It was elected to waste it rather than try to process it.

Later, a grizzly was used to separate the rock from the soil. The rock was processed for riprap and the soil stockpiled for use in the random zone. The remaining excavation was divided into two classifications. The upper zone contained weathered crystalline limestone of suitable quality to be used as riprap. The lower zone contained unweathered limestone and claystone seams not suitable for riprap, but adequate for rockfill. These zones were selectively excavated and used as stated.

The rockfill zone of the dam now required more material than would be available from the emergency spillway excavation. Rather than quarry additional rockfill, it was decided to reduce the rockfill zone to be compatible with the volume of material available. A minimum horizontal thickness of 16 ft. was maintained for workability. The purpose of this zone is to use materials required to be excavated from the emergency spillway and to act as slope protection for the back of the dam. Specifications were modified to allow quarry run material not exceeding 24 in. in size.

Difficulties with compacting material adjacent to piezometer clusters at Station 50+00 and 60+00 are discussed in Appendix 2.5B along with corrective action taken.

Closure of the stream began on July 28, 1976. The details of this operation are described in Section 2.5.6.7.1. The dam was completed on June 16, 1977.

2.5.6.9.2 Safe Shutdown Impoundment Dam

Estimated construction quantities for the Safe Shutdown Impoundment Dam are as follows:

1.	Excavation	447,800 C.Y.
2.	Impervious Fill	63,900 C.Y.
3.	Filter A	22,800 C.Y.
4.	Filter B	22,800 C.Y.
5.	Rock Fill - Graded	450,700 C.Y.
6.	Rock Fill - Quarry Run	97,600 C.Y.

Construction of the SSI Dam began on February 10, 1975, with the clearing and grubbing of the dam's foundation. Details of and problems encountered during the foundation and abutment excavation and treatment are discussed in Section 2.5.6.3.2. Figures 2.5.6-4A thru 2.5.6-4G are a series of photographs of the dam during construction.

The most significant problem in the foundation excavation was that weathered and unsound rock was encountered deeper than expected. It was originally estimated that 305,000 C.Y. of material would have to be removed to secure a proper foundation; however, 548,300 C.Y. were removed.

Specifications required all slopes in the abutments to be 3 (H) on 1(V). This was to be accomplished with dental concrete where necessary. Excavation of the rock ledges tended to break vertical, and the claystone ledges had to be excavated vertical. Sloping there verticals to 3 (H) on 1 (V) slope would require a considerable amount of concrete; therefore, the specifications were modified to allow a 1 on 1 slope, with a maximum of 30 inches of vertical rock face when in rock. This applied to the rockfill and filter zones only. In the core zone, the faces were hand trimmed to a 1 on 1 slope and all claystone layers were protected from weathering with 1-1/2 inches of pneumatically-placed concrete. The specifications for dental concrete required that it be consolidated to a dense impervious mass. When placed on a 1 on 1 slope, it could not be vibrated without flowing down slope. Since this material is used only under the rockfill and filter zones where being impervious is not important, the specifications were changed to allow the use of fill concrete. Fill concrete was consolidated by vibration insofar as possible then by tamping. Core test samples demonstrated that the compressive strength of this material was adequate to support the rockfill.

On April 13, 1976, a joint inspection of the foundation was made by the Freese and Nichols Project Engineer and the Mason-Johnston Project Geotechnical Consultant, resulting in permission being given to proceed with backfill. The presence of weathered (Fractured) layers of limestone was noted in the right abutment. Attempts to remove this material were unsuccessful and it was believed that this material extended through the abutment. Removal of this material was not required since it was structurally sound and located above elevation 769.5 where water

tightness is not important. The fractures were judged to be tight enough not to cause piping of the core material during its limited exposure to flood water.

Sources of embankment materials were as follow:

1. Rock Fill - Borrow “B” and “C” quarries as defined in Appendix 2.5A, “Construction Records and Design Verification of SSI Dam.”

2. Impervious Core - Selected borrow pits in Panther Branch valley below the SSI, and in Squaw Creek Valley above SCD.

3. Filter Materials - Commercial sources.

The time required to carry out effectively selective quarry operation in the plant site to obtain sufficient material to construct the SSI Dam was prohibitive when compared to the excavation schedule for the plant. Quarries of satisfactory quality were located alone Squaw Creek, two miles upstream from SCD.

Rock fill was selectively quarried from these sources to minimize claystone content and brought to a stockpile near the crusher. Sufficient material was stockpiled before impoundment of water in SCR since the quarry would be one of the first areas flooded. The rock material was hen run through the crusher and either placed as embankment or stockpiled.

Rock fill was dumped from end-dump trucks and spread into a two-ft- thick layer with a dozer. Segregation problems caused by spreading were corrected through modifying the dozer blade by adding “wings” to keep the larger stones from rolling to the side. Compaction was accomplished by four passes with a 10 ton vibrating roller.

The preirrigated impervious core material was processed with a mixer prior to loading in dump trucks and being transported to the fill. The material was dumped and spread into a loose lift not greater than 8 inches thick and compacted by a minimum of 8 passes of a sheepsfoot roller.

Originally up to a 12-inch loose lift thickness was allowed. Considerable difficulty was experienced in compacting the filter zones to the 80 percent relative density required. This problem was solved by reducing the lift thickness from 12 inches to 8 inches and compacting with hand operated vibrating sleds.

In August 1976, it was determined that a portion of the filter material did not comply with gradation requirements. At this time, the top of the embankment was at approximately elevation 756. An investigation of the location and extent of the undesirable material was jointly conducted by Freese and Nichols and Mason-Johnston. It was determined that acceptable filter material was present in all locations below elevation 747.5. All of the undesirable filter material was removed down to elevation 747.5. The mechanical requirements of the removal process also required the removal of limited quantities of acceptable filter, rock shell and core material. The excavated areas were then rebuilt with materials meeting the specifications.

The presence of the undesirable filter material in the dam embankment and the subsequent removal of the material and its replacement with desired material were determined to constitute a reportable deficiency as defined by paragraph 10 CFR 50.55(e) (1) (iii). A complete report of the

deficiency and the corrective actions taken was made to the Nuclear Regulatory Commission [127 and 128].

The embankment was 50 percent complete on August 20, 1976, a hold point to core drill the impervious material for geotechnical evaluation. The SSI Dam was completed on May 12, 1977, also a hold point to core drill the impervious material for geotechnical evaluation. The findings and details of the geotechnical evaluations, performed by Mason-Johnston, Inc., are included in Appendix 2.5A entitled "Construction Records and Design Verification of SSI Dam.:"

2.5.6.10 Operational Notes

The Safe Shutdown Impoundment Dam and the Squaw Creek Dam have been monitored as discussed in Section 2.5.6.8 and the performance has been satisfactory. The performance of the Safe Shutdown Impoundment Dam and the Squaw Creek Dam will continue to be monitored and any unsatisfactory conditions will be evaluated and corrected.

LIST OF PERSONNEL AND AGENCIES CONTACTED

Mr. Marvin Armand - Austin Department Building Inspection

Mr. Charles Betinger - Waco Water Department

Mr. Gunner Brune - Texas Water Development Board

Mr. James Burnete - Austin Superintendent of Streets

Dr. L. E. Garner - Texas bureau of Economic Geology

Mr. Benjamin Glaesser - Texas Highway Department

Dr. Groat - Texas Bureau of Economic Geology

Dr. O. H. Hayward - Baylor University

Dr. Gene Herrin - Southern Methodist University

Mr. G. D. Howell - Baylor University

Dr. Ralph O. Kehle - University of Texas

Mr. Andrew Kurie - Dow Chemical Corporation

Mr. Ted Lenox - Austin Water Department

Dr. Frank Lozo - Consulting Geologist

Mr. Robert McKinney - Texas Highway Department

Mr. William Reid - University of Texas

Mr. Russell - Waco Streets Department

Mr. Wally Samuelson - Corps of Engineers

Mr. James Sansom - Texas Water Development Board

Dr. Torrey - Consulting Geologist

Mr. William Trippett - Baylor University

Dr. Jan turk - University of Texas

Mr. Alan Walker - Waco Sewer Department

Mr. Edward A. Wendlant - Consulting Geologist

Mr. Peter N. Wiggins - Consulting Geologist

PERSONNEL CONTACTED DURING FIELD FAULT INVESTIGATION

Dr. Hayward, Baylor University Professor

Dr. Kehle, University of Texas professor

D. D. Reasor, University of Texas

Mr. Russel, Waco Streets, Superintendent

Jack Corsevall, Waco City

Alan Walker, Waco City Sewer

Charlie Betengor, Waco City Water

Mr. Ben Glaesser, Texas Roads, Waco office

Mr. McClellan, Texas Highway Department

Benford Turner, District 9, Texas Highway Department

Bill Perry, Texas Highway Department

Robert McKinney, Texas Highway Department

Mr. Bynum, Hill County Highway Department, Texas Highway Department, Hill County

Dr. Torrey, Private Geologist, Austin, Texas

Marvin Armand, Austin Building Inspector

James Burnete, Austin Streets Superintendent

Mr. Sanders, Austin, Water District

Ted Lenox, Austin City

David Barrow, Builder, Austin

Peter Wiggins, Private Geologist

TABLE 2.5.1-1
TABULATION OF PRINCIPAL FAULTS - TEXAS

Structure Name (County)	Basis of Identification			Age of Movement		Characteristics	Distance From Site (miles)
	Surface	Borehole	Geophysics	Major	Last		
Balcones Fault Zone (Hill), McLennan) 15,13	X	X		Oligocene, Beginning in Cretaceous	Miocene?	Strikes NNE; SE side down; 1200-1700' maximum displacement	44
Luling-Darst Creek Fault Zone 15,47	X	X	X	Oligocene, Beginning in Cretaceous	Quarter-nary	Strikes NNE; NW side down; 1500-2000 feet maximum displacement; 450' average displacement	150
Luling-Mexia-Talco Fault Zone (Bowie, Morris, Titus, Franklin, Delta, Hunt, Kaufman, Navarro, Limestone, Ellis, Southwest) 13	X	X	X	Oligocene, Beginning in Cretaceous	Eocene?	Graben, str kes NNE to EW, 600' displacement; 500 mi. long; NW and SE sides down; 30°-55° dips.	30
Fort Chadbourne Fault (Schleicher, Tom Green, Runnels, Taylor) 13			X			Strikes N-S; E side down	40
Rodessa Fault Zone (Marion, Cass) 13,47		X				Strikes NE; related to Sabine Uplift	180
Mt. Enterprise Fault Zone (Anderson Chero-kee, Rusk, Shelby) 47	X	X	X	mid-Cretaceous		Strikes WSW; Graben; 30°-60° dips. Related to Sabine uplift.	140

TABLE 2.5.1-2
TABULATION OF PRINCIPAL FAULTS - TEXAS

Structure Name (County)	Basis of Identification			Age of Movement		Characteristics	Distance From Site (miles)
	Surface	Borehole	Geophysics	Major	Last		
Muenster Arch (Montague, Cooke, Denton) 13		X		Late Paleozoic		Strikes NW; related to Red River uplift	60
Fort Worth Basin (Bosque, Johnson, Tarrant, Denton, Westward) 13		X		Pennsylvanian		Strikes NW	0
Bend Arch (McCulloch, Coleman Eastland, Stephens, Young) 13		X		Late Paleozoic	Post Permian	Strikes N-S; Northward plunge; related to Llano uplift	30
East Texas Embayment (Axis in Houston, Anderson Smith, Wood, Camp, Cass) 16,47	X	X	X	Early Mesozoic	Cenozoic	Strikes NNE	90
Llano uplift (Mason, Llano, San Saba, Burnet, Blanco, Gillespie) 13,47	X			Post Early Ordovician	Pre-Late Penn.	Dome; 40 x 70 miles	70
Fort Worth Syncline (Tarrant, Wise, Jack, Clay) 13		X				Strikes ESE	60
Red River Uplift (Denton to Cottle) 13		X	X	Mid-Paleozoic		Strikes E-W; 200 miles long, few miles wide	120
Edwards Arch (Kimble, Edwards) 13		X				Strikes NE; related to Llano Uplift	180
San Marcos Arch (Axis in Blanco, Hays, Caldwell, Gonzales) 13,47	X	X		Late Paleozoic	Early Cenozoic	Strikes NW; Se plunge; related to Llano Uplift	170
Lampasas Arch (Lampasas) 13		X				Strikes NE; related to Llano Uplift	40
Marathon-Quachita Tectonic Belt (Mexico, Texas, S.E. Oklahoma, Arkansas, Miss., S.W. Alabama) 13,47		X		Mid to late Paleozoic		Strikes NNE nearest site 1300 miles long, minimum 90 miles wide.	35

TABLE 2.5.1-3
TABULATION OF PRINCIPAL FAULTS - OKLAHOMA, ARKANSAS, LOUISIANA

Structure Name (County)	Basis of Identification			Age of Movement		Characteristics	Distance From Site (miles)
	Surface	Borehole	Geophysics	Major	Last		
Boktukola Thrust Fault (Oklahoma-Choctaw, Pusnmataha, McCurtain; Arkansas) 3	X			Pennsylvanian		Str kes NE; thrust toward NW; related to Quachita uplift	180
Winding-stair Thrust Fault (Oklahoma-Octavia, Latimer, Pittsburgh, Atoka; Arkansas) 3	X			Pennsylvanian		Str kes NE to E; thrust toward NW; related to Quachita uplift	175
Ti Valley Thrust Fault (Oklahoma-Octavia, Latimer, Pittsburgh, Atoka; Arkansas) 3	X			Pennsylvanian		Str kes NE to E; thrust toward NW; related to Quachita uplift	160
Chocktaw Thrust Fault (Oklahoma-Latimer, Pittsburgh, Atoka; Arkansas) 3	X			Pennsylvanian		Str kes NE to E; thrust toward NW; related to Quachita uplift	160
Pine Mountain Thrust Fault (Oklahoma-Latimer, Pittsburgh, Atoka) 3	X			Pennsylvanian		Str kes NE to E, thrust toward NW; related to Quachita uplift	180
Jackfork Mountain Thrust Fault (Oklahoma-Latimer, Pusnmataha, Atoka) 3	X			Pennsylvanian		Str kes NE to E; thrust toward NW; related to Quachita uplift	170
Octavia Thrust Fault (Oklahoma-Pushmataha) 3	X			Pennsylvanian		Str kes NE to E; thrust toward NW; related to Quachita uplift	180
Bancroft Fault Zone (Louisiana and Texas) 3	X			Tertiary		Str kes NE to E, normal down to coast faults	180
Reagan Fault (Oklahoma) 3	X			Pennsylvanian		Str kes NW; down to SE; related to Arbuckle uplift	150
Millcreek Fault (Oklahoma) 3	X			Pennsylvanian		Str kes NW; down to SW; related to Arbuckle uplift	150
Sulphur Fault (Oklahoma) 3	X			Pennsylvanian		Str kes NE; down to NE; related to Arbuckle uplift	160
Washita Valley Fault (Oklahoma) 3	X			Pennsylvanian		Str kes NW; down to NE Related to Arbuckle uplift	140

TABLE 2.5.1-11
SURVEY OF REPORTED BOTTOM-HOLE PRESSURE IN HOOD AND SOMERVELL COUNTIES, TEXAS

(Sheet 1 of 2)

Well I.D. No.	Well Name and Location	County	Formation	Depth, ft.	Shut-in Pressure	Gradient psi/ft.	Remarks
	Delray Oil, Inc. No. 1 G. P. Snyder "R" J. Echols Survey A-24 3 mi. south of Glen Rose	Somervell	Ellenburger	6,049-6,114	2,761# 1 hr. 30 min.	.45643	Recovered 552' muddy salt water (chlorides 86,000 ppm). Dry and abandoned 10-16-75.
	Cities Service No. 1-N Wilson James Cole Survey A-91 2 mi. North of Lipan	Hood	Ellenburger	5,182-5,285	2,318# 30 min. (Probable not Stabilized.)	.44732	Open hole drill-stem test recovered 180' gas in drill pipe; 120' salty, gas-cut mud; 180' gas-cut muddy salt water; 1,260' gas-cut salt water. Dry and abandoned 9-22-61.
	Sunray No. 1 John Black Lower Thomas Robinson Survey 3.5 mi. west of Thorp Springs	Hood	Ellenburger	5,438-5,448	2,550# Time not reported.	.46892	Recovered 4,200' salt water in 2-hr. open hole drill-stem test. Dry and abandoned 7-7-51.
17	Gulf Oil Corp. No. 6 Bratten Ranch T. J. Stansbury Survey A-498 3 mi. east of Paluxy	Hood	Marble Falls	4,686-4,696	1,807# Time not reported. (After treatment.)	.38520	Gas well (CAOF 1,950 Mcfgpd). Completed 7-18-77
16	Gulf Oil Corp. No. 8 Bratten Ranch Thomas Stansbury Survey A-498 3 mi. east of Paluxy	Hood	Marble Falls	4,696-4,776	1,746# Time not reported.	.36866	Gas well (CAOF 2,725 Mcfgpd). Completed 6-16-77
	Cities Service No. 1-N Wilson James Cole Survey A-91 2 mi. north of Lipan	Hood	Big Saline	4,141-4,201	1,983# 30 min.	.47887	Open hole drill-stem test flow estimated 4.4 million cubic feet of gas per day; recovered 70' slightly gas and salty cut mud, 60' gassy and heavy salt water-cut mud, 30' muddy salt water.
4	Tri-Venture, II No. 1 Trotter J. Doan Survey 13 mi. southwest of Granbury	Hood	Big Saline	4,770-4780	1,861# Time not reported. (After treatment.)	.38973	Gas well (CAOF 378 Mcfgpd). Completed 11-7-77.
18A	Sirius Energy Co. No. 1 J. T. Parker Cyrus T. Egery Survey A-169 1 mi. north and 4 mi. east of Paluxy	Hood	Big Saline	4,730-4,746	1,822# Time not reported. (After fracturing formation for production)	.38455	Gas Well (CAOF 174 Mcfgpd). Completed 1-23-78.

TABLE 2.5.1-11
SURVEY OF REPORTED BOTTOM-HOLE PRESSURE IN HOOD AND SOMERVELL COUNTIES, TEXAS

(Sheet 2 of 2)

Well I.D. No.	Well Name and Location	County	Formation	Depth, ft.	Shut-in Pressure	Gradient psi/ft.	Remarks
	Delray Oil, Inc. No. 1 Bramlett Isacc Addison Survey A-2 4 miles south of Glen Rose	Somervell	Strawn	2,610-2,708	855# 1 hr. 30 min.	.32759	Open hole drill-stem test recovered 60' drilling mud. Dry and abandoned 5-22-76.
			Strawn	2,590-2,621	370# 2 hrs.	.14286	Open hole drill-stem test recovered 25' drilling mud.
	Delray Oil, Inc. No. 1 G. P. Snyder "R" J. Echols Survey A-24 3 mi. south of Glen Rose	Somervell	Strawn	2,964-2,995	1,064# 3 hrs.	.35897	Recovered 15' drilling mud.
			Strawn	2,428-2,464	837# 2 hrs.	.34473	Recovered 35' drilling mud.
	Gulf Oil Corp. No. 3 Bratten Ranch J. B. White Survey A-576 10 mi. southeast of Tolar	Hood	Strawn	4,054-4,064	1,181# Time not reported.	.29095	Gas well (CAOF 742 Mcfgpd). Completed 3-31-77.
	Gulf Oil Corp. No. 2 T. H. Nix Lewis Boatwright Survey A-33 3 mi. south of Tolar	Hood	Strawn	2,802-2,812	599# Time not reported.	.21339	Gas well (CAOF 161 Mcfgpd). Completed 2-21-78.
	Gulf Oil Corp. No. 1 V. Swain Lewis Boatwright Survey A-33 3 mi. south of Tolar	Hood	Strawn	2,762-2,768	689# Time not reported.	.24918	Gas well (CAOF 3,200 Mcfgpd). Completed 9-27-77.
	Gulf Oil Corp. No. 1 D. McIntosh T. W. Dundick Survey A-23 4 mi. southeast of Tolar	Hood	Strawn	4,356-4,380	1183# Time not reported.	.27083	Gas well (CAOF 3,090 Mcfgpd). Completed 11-18-76.

TABLE 2.5.2-1
MODIFIED MERCALLI INTENSITY SCALE OF 1931 (Abridged)

I. Not felt except by a very few under especially favorable circumstances. (I Rossi-Forel Scale.)

II. Felt only by a few persons at rest, especially on upper floors of buildings. Delicately suspended objects may swing. (I to II Rossi-Forel Scale.)

III. Felt quite noticeably indoors, especially on upper floors of buildings, but many people do not recognize it as an earthquake. Standing motorcars may rock slightly. Vibration like passing of truck. Duration estimated. (III Rossi-Forel Scale.)

IV. During the day felt indoors by many, outdoors by few. At night some awakened. Dishes, windows, doors disturbed; walls make creaking sound. Sensation like heavy truck striking building. Standing motorcars rocked noticeably. (IV to V Rossi-Forel Scale.)

V. Felt by nearly everyone, many awakened. Some dishes, windows, etc., broken; a few instances of cracked plaster; unstable objects overturned. Disturbances of trees, poles, and other tall objects sometimes noticed. Pendulum clocks may stop. (V to VI Rossi-Forel Scale.)

VI. Felt by all, many frightened and run outdoors. Some heavy furniture moved; a few instances of fallen plaster or damaged chimneys. Damage slight. (VI to VII Rossi-Forel Scale.)

VII. Everybody runs outdoors. Damage negligible in buildings of good design and construction; slight to moderate in well-built ordinary structures; considerable in poorly built or badly designed structures; some chimneys broken. Noticed by persons driving motor cars.

VIII. Damage slight in specially designed structures; considerable in ordinary substantial buildings with partial collapse; great in poorly built structures. Panel walls thrown out of frame structures. Fall of chimneys, factory stacks, columns, monuments, walls. Heavy furniture overturned. Sand and mud ejected in small amounts. Changes in well water. Persons driving motorcars disturbed. (VIII+ to IX- Rossi-Forel Scale.)

IX. Damage considerable in specially designed structures; well-designed frame structures thrown out of plumb; great in substantial building with partial collapse. Buildings shifted off foundations. Ground cracked conspicuously. Underground pipes broken. (IX+ Rossi-Forel Scale.)

X. Some well-built wooden structures destroyed; most masonry and frame structures destroyed with foundations; ground badly cracked. Rails bent. Landslides considerable from river banks and steep slopes. Shifted sand and mud. Water splashed (slopped) over banks. (X Rossi-Forel Scale.)

XI. Few, if any (masonry) structures remain standing. Bridges destroyed. Broad fissures in ground. Underground pipelines completely out of service. Earth slumps and land slips in soft ground. Rails bent greatly.

XII. Damage total. Waves seen on ground surface. Lines of sight and level distorted. Objects thrown upward into the air

a) Depth from existing ground surface.

TABLE 2.5.4-5
INITIALLY SELECTED VALUES OF PREEXCAVATION-DYNAMIC FOUNDATION DESIGN PARAMETERS

Foundation Material	Compressional Wave Velocity, Vc (ft/sec)	Shear Wave Velocity (ft/sec)	Wave Density* (lbs/cu ft)	Insitu Wet Poisson's Ratio (ν)	Shear Modulus (G) or Modulus of Rigidity (lbs/sq in)
Weathered Rock	2,600	1,000	144	.35	4.5×10^4
Moderately Weathered to Fresh Rock (Glen Rose Limestone above approximately elevation 770)	9,500 to 11,000	5,500 to 6,000	150	.30	8.0×10^5
Underlying Massive Fresh Rock (Glen Rose Limestone below approximately elevation 770)	11,000 to 12,500	6,000 to 6,500	155	.27	1.2×10^6
Underlying Twin Mountains Rock	7,000 to 8,000	3,200	135	.32	3.0×10^5

Young's Modulus, $E = 2(1 + \nu) G$.

$$\text{Mass Density} = \rho = \frac{\text{Insitu Density}}{32.2}$$

$$E = V_C^2 \frac{(1+\nu)(1-2\nu)}{(1-\nu)}$$

- Sandstone/Claystone	varies	varies	23	10,452	24	4691	0.37
MINERAL WELLS	443 - 503+	366 - 306	20	10,162	19	4339	0.39

TABLE 2.5.4-5G
DYNAMIC ROCK PROPERTIES DETERMINED BY LABORATORY TESTING OF CORE SAMPLES

		Unit Weight (PCF)		Shear Modulus (KSI) and Damping Ratio (%)		
Lithology	Formation	No. of Tests	Mean	No. of Tests	Mean Shear Modulus	Mean Damping Ratio
	Glen Rose	17	137.8	4	69	4.4
Claystone	Twin Mountains	11	137.9	2	110	5.0
	All	28	137.9	6	83	4.6
	Glen Rose	12	154.4	4	727	1.9
Limestone	Twin Mountains	3	156.4	1	729	2.3
	All	15	154.8	5	727	2.0
	Glen Rose	1	144.4	-	-	-
Sandstone	Twin Mountains	20	135.0	6	166	4.7
	All	21	135.4	6	166	4.7
	Total	64	Total	17		

NOTE: Samples were obtained from S/L cluster borings S-1, S-1A, L-1. L-2 core samples were not tested.

TABLE 2.5.4-5H
DYNAMIC FOUNDATION DESIGN PARAMETERS BASED ON PREEXCAVATION AND POSTCONSTRUCTION GEOPHYSICAL SURVEYS

Zone Description			Seismic Velocities (Ft/Sec)		Unit Weight (PCF)	Shear Modulus[a] (KSI)	Poisson's Ratio
Depth (ft)	Elevation (ft)	Thickness (ft)	Compressional Vp	Shear Vs			
0[b]	810	23[c]	9400	4500	150	650	0.35
23	787	16	5600	2700	145	230	0.35
39	771	161	11400	5500	155	1000	0.35
200	610	160	6400	3100	135	280	0.35
360	450		9400	4500	150	650	0.35

a) Shear Modulus = Mass Density $(Vs)^2$

b) Plant Grade

c) Some boring logs indicate substantial claystone strata within this zone. Such strata are treated as subzones and properties of the zone extending from elevation 787 to elevation 771 are applied.

APPENDIX 2.5A - CONSTRUCTION RECORDS AND DESIGN VERIFICATION OF SSI DAM

2.5A.1 DESIGN VERIFICATION AT FIFTY PERCENT (50%) CONSTRUCTION COMPLETION

In order to verify that the SSI Dam was constructed according to design criteria, two borings were drilled through the impervious core when the embankment was approximately 50% complete. The location of the borings were as follows:

Boring No.	Station	Ground Surface Elevation
SSI-1	6+00	756.4
SSI-2	10+00	756.3

Continuous samples of the impervious core were taken utilizing a Shelby-tube sampler. A detailed log of each boring is shown on the attached Figures 2.5A-1 & -2.

The following laboratory tests were conducted on samples obtained from the impervious core: unit dry weight determinations, Atterberg limit determinations and hand vane shear tests. The results of these tests are summarized on Table 2.5A-1, -2 for Borings SSI-1 & 2, respectively. The results of the Atterberg limit tests confirmed that the impervious core met the liquid limit specification requirement. The hand vane shear tests were conducted as a relative indicator of the uniformity of the layer compaction. For each specimen tested, a vane shear reading was made in both the top and bottom of the sample. Differences in the readings are interpreted to represent the relative variation in the compaction of the embankment. Only slight variations were noted in the vane shear readings.

A series of hydrometer and sieve analyses were conducted on representative samples and are shown on Figure 2.5A-3. All the tested specimens are classified as CL material.

The strength parameters of the impervious core were evaluated by a series of unconfined compression tests as well as three (3) multi-stage triaxial compression tests. Summarized on Table 2.5A-3 are the results of the unconfined compression tests. Figure 2.5A-4 is a typical stress-strain curve developed for one of the unconfined compression tests. The results of the triaxial tests are summarized on Figure 2.5A-5. The results confirmed that the material actually possessed a strength higher than assumed during design.

In summary, the results of these tests confirmed that all design criteria and specification requirements had been met at 50 percent completion of the embankment.

2.5A.2 DESIGN VERIFICATION AT ONE HUNDRED PERCENT (100%) CONSTRUCTION COMPLETE

Upon completion of the SSI dam, a core boring was drilled through the entire embankment at centerline station 9+75 to obtain undisturbed Shelby-tube samples throughout the entire depth of the impervious core section. A detailed “Log of Boring” is attached as Figure 2.5A-6.

Utilizing all the samples obtained of the impervious core, a series of laboratory tests, including Atterberg Limits, unit dry weight determinations, and hand vane shear tests was conducted. The results are summarized on Table 2.5A-4. The results of the Atterberg limit tests confirmed that the impervious core met the liquid limit specification requirement. The results of the vane shear readings show the material to be relatively uniform in compaction.

To evaluate the shear strength of the impervious core, a series of consolidated undrained triaxial tests were conducted with the results plotted on Figure 2.5A-7. This is a plot of the Mohr Stress circles developed from the individual tests with the design criteria failure envelope drawn showing its relationship to the test results. As can be seen on this Figure, the results of the CU triaxial tests fit very closely to the adopted design strengths.

On Figures 2.5A-8 through 10 are results of consolidation tests to the impervious core.

The results of the testing shows that the impervious core met all specification requirements and design criteria.

2.5A.3 FIELD DENSITY TEST DISTRIBUTION

To further show the adequacy of the completed embankment, a plot showing the distribution of density control tests has been developed and is shown on Figures 2.5A-11, Sheets 1 through 15. These plots show the distribution of the density tests conducted for the impervious core, filter zone and rock fill material at 5-foot intervals through the embankment. In addition, the test results have been shown in histogram plots. These histogram plots are shown as Figures 2.5A-12 through 15. In summary, the results showed the following:

Data Base	No. of Tests	Mean	Standard Deviation	Design Criteria
% Compaction of Impervious Core	309	102%	2.3	>95%
Moisture Content Variation, W_o-W_f	309	-0.59%	1.1	-3%+1%
Percent Relative Density-Filter	585	96.7%	9.3	>80%
Rock Fill Density	75	125.0pcf	9.8	115pcf

Histograms of the grain size distributions for the rock fill, filter A and filter B are presented in Figures 2.5A-19 thru 2.5A-21.

2.5A.4 DYNAMIC STABILITY RE-EVALUATION

During construction a series of cyclic triaxial tests were conducted on filter “A” material to verify whether or not his material met the adopted design criteria as discussed in Section 2.5.6.4.3.4. According to the test results presented in Section 2.5.4.7, filter “A” material failed to meet the adopted design criteria. Based on the cyclic triaxial test results for the filter “A” material, Figure 2.5A-16 was developed which relates the cyclic strength of the material based on a failure criteria for both 5% and 10% of double amplitude strain. From this figure, new cyclic design criteria for 10 cycles of loading and a failure criteria of 5% double amplitude strain was developed for the

filter material and is shown on Figure 2.5A-17. Utilizing this new design criteria, a new seismic stability cross-section of the SSI Dam was developed. Figure 2.5A-18 relates shear stress induced by the artificial ground motion, τ_d, to the cyclic shear stress required to cause 5% double amplitude strain, τ_f. As was the cause in Section 2.5.6.5.2.6, the ratio τ_d/τ_f represents a local safety factor against the development of 5% strain in 10 cycles of loading. Figure 2.5A-18 is the plot showing the calculated local safety factors at the nodal points of the finite element grid. Several points had values less than one (1) for the rock shell at points on the outer slope surfaces near the crest of the dam. These values result from the presence of little or no normal stress. An interpretation of these results would be that, during the occurrence of the SSE, an occasional rock particulate on the outer slope may be displaced enough to tumble or roll some short distance down the slope.

Near the top of the filter zone, two nodal points have safety factors calculates as 0.94 and 0.97. This is interpreted as meaning that, during the occurrence of the SSE, the upper zone of the filter material will experience 5% double amplitude strains. This will not result in the liquefaction of the filter material and will not impair the function of the dam.

APPENDIX 2.5B - CONSTRUCTION RECORDS AND DESIGN VERIFICATION OF SQUAW CREEK DAM

2.5B.1 DESIGN VERIFICATION AT 50% CONSTRUCTION COMPLETION.

In order to verify that the Squaw Creek Dam embankment met the design criteria at 50% construction completion, four (4) borings were drilled through the embankment as follows:

Boring No.	Station	Embankment Zone	Ground Elevation
SCD-1	60+00,60'D.S.	Random	701.0
SCD-2	59+50,20'D.S.	Random	702.0
SCD-2	59+50,20'U.S.	Impervious Core	680.0
SCD-4	58+00,20'U.S.	Impervious Core	709.0

Near continuous sampling of the earth embankment was achieved by the utilization of a Shelby-tube sampler. A detailed log of each boring is shown on Figures 2.5B-1 thru 2.5B-4, respectively.

From each boring, a series of Atterberg Limits, Unit Dry Weight Determinations and Hand Vane Shear Tests were conducted. The test results for each Boring are summarized on Table 2.5B-1 thru 2.5B-4, respectively. The results of the classification tests confirm that the impervious core and random consist of CL soils, with the higher plastic clays in the impervious core. The Hand Vane Shear tests were conducted to provide a relative indicator of the uniformity of the embankment layer compaction. For each specimen tested, a Vane Shear reading was made on both the top and bottom of the samples. Differences in the readings represent the relative variation in the compaction of the embankment layers. Several soft zones were detected in Boring SCD-2 and SCD-4; however, these zones were isolated and the overall consistency of the material is considered stiff.

The strength parameters of the embankment fill were evaluated by a series of fourteen (14) Unconfined Compression Tests and six (6) Multistage, Q, Triaxial Compression Tests. The results of the Unconfined Compression Tests are summarized on Table 2.5B-5, with a typical stress-strain curve developed for one of the tested specimen shown on Figure 2.5B-5. The results of the Triaxial tests are shown on Figure 2.5B-6. The test results confirm that the materials actually possess a higher cohesive strength than assumed during design.

2.5B.2 FIELD DENSITY TEST DISTRIBUTION

To further show the adequacy of the completed embankment, plots showing the distribution of density control tests have been developed and are shown on Figures 2.5B-7, Sheets 1 through 33. These plots show the distribution of the density tests conducted for the impervious core random zone and filter zone at 5-foot intervals through the embankment. In addition, the tests

results have been shown in histogram plots, which are shown as Figures 2.5B-8 through 10, respectively. In summary, the results showed the following:

Data Base	No. of Tests	Mean	Standard Deviation	Design Criteria
% Compaction of Impervious Core	2959	100.3%	2.7	95%
Moisture Content Variation, W_o-W_f	3128	-0.59%	1.3	-3%+1%
Percent Relative Density-Filter	148	102.3%	13.5	80%

3.0 DESIGN OF STRUCTURES, COMPONENTS, EQUIPMENT AND SYSTEMS

3.1 CONFORMANCE WITH NUCLEAR REGULATORY COMMISSION (NRC) GENERAL DESIGN CRITERIA

This section briefly discusses the extent to which the design criteria for the plant structures, systems, and components important to safety comply with Title 10, Code of Federal Regulations, Part 50 (10 CFR Part 50), Appendix A, General Design Criteria (GDC) for Nuclear Power Plants. Each criterion is first quoted directly from 10 CFR Part 50 and then discussed. In the discussion of each criterion, it is shown how the CPNPP design meets the criterion, and the sections of the FSAR, where more detailed information is presented to demonstrate compliance with the criterion, are referenced.

3.1.1 OVERALL REQUIREMENTS

3.1.1.1 Criterion 1 - Quality Standards and Records

"Structures, systems, and components important to safety shall be designed, fabricated, erected, and tested to quality standards commensurate with the importance of the safety functions to be performed. Where generally recognized codes and standards are used, they shall be identified, evaluated to determine their applicability, adequacy, and sufficiency, and shall be supplemented or modified as necessary to assure a quality product in keeping with the required safety function. A quality assurance program shall be established and implemented in order to provide adequate assurance that these structures, systems, and components will satisfactorily perform their safety functions. Appropriate records of the design, fabrication, erection, and testing of structures, systems, and components important to safety shall be maintained by or under the control of the nuclear power unit licensee throughout the life of the unit [1]."

Discussion

Structures are identified and classified in accordance with the requirement that they be designed to withstand the effects of earthquakes, as delineated in Section 3.2.

The systems and components of the facility are classified according to their importance in the prevention and mitigation of accidents. Reactor components use the classification system developed by American National Standards Institute (ANSI) N18.2-1973, Nuclear Safety Criteria for the Design of Stationary Pressurized Water Reactor Plants. Classifications and any deviations are described in Section 3.2. Each component is given a safety class designation.

The codes, standards, and quality control applicable to each type of component are identified in pertinent equipment specifications. Where applicable, design and fabrication are in accordance with the codes specified in 10 CFR Part 50, Section 55a. See Section 5.2.1.1. Alternative requirements, as provided by ASME Code Cases, are utilized at CPNPP in accordance with 10 CFR Part 50, Section 55a(a)(3). By reference to ASME Section III requirements in the procurement specifications, the use code cases by mechanical equipment suppliers requires mutual consent of the Owner or his agent and the manufacturer. The ASME Code Cases which are used for design and erection at CPNPP are identified in the appropriate mechanical design and erection specifications or the Brown & Root QA Manual; conditionally-approved Code Cases will show justification for their use, as required by NRC, in these documents. This application of ASME Code Cases is documented on the ASME Data Report Forms. For further discussion, see

the text concerning Regulatory Guide 1.85 in Section 1A(N). The quality assurance (QA) program that is implemented to ensure that safety-related systems, components, and structures perform as intended is discussed in Chapter 17. The QA program conforms to the intent of 10 CFR Part 50, Appendix B, Quality Assurance Criteria for Nuclear Power Plants and Fuel Reprocessing Plants. Those items for which the requirements of 10 CFR Part 50, Appendix B, are met are listed in the list of quality assured items in Appendix 17A.

Chapter 14 describes initial tests to ensure performance of installed equipment commensurate with the importance of the safety function.

The component safety classifications are also shown on the flow diagrams presented with their respective sections. Records for the design, fabrication, erection, and testing of safety-related systems, components, and structures are maintained as described in Chapter 17.

Westinghouse, in accordance with the Westinghouse Nuclear Energy System Division's (WNESD's) Quality Assurance Plan, maintains (either in its possession or under its control) a complete set of records of the design, fabrication, construction, and testing of safety components which it supplies.

The Westinghouse QA program conforms to the requirements of 10 CFR Part 50, Appendix B, and is discussed in Westinghouse Commercial Atomic Power (WCAP) 8370, Revision 7A.

3.1.1.2 Criterion 2 - Design Bases for Protection Against Natural Phenomena

"Structures, systems, and components important to safety shall be designed to withstand the effects of natural phenomena such as earthquakes, tornadoes, hurricanes, floods, tsunami, and seiches without loss of capability to perform their safety functions. The design bases for these structures, systems, and components shall reflect: (1) Appropriate consideration of the most severe of the natural phenomena that have been historically reported for the site and surrounding area, with sufficient margin for the limited accuracy, quantity, and period of time in which the historical data have been accumulated, (2) appropriate combinations of the effects of normal and accident conditions with the effects of the natural phenomena, (3) the importance of the safety functions to be performed [1]."

Discussion

The natural phenomena and their magnitude are selected in accordance with their probability of occurrence at the Comanche Peak site. The design is based on the most severe of the natural phenomena recorded for the site, with an appropriate margin to account for uncertainties in the historical data. The natural phenomena postulated in the design are presented in Sections 2.3, 2.4, 2.5, and 3.3. The design criteria for the structures, systems, and components affected by each natural phenomenon are presented in Sections 3.2, 3.3, 3.4, 3.5, 3.7, and 3.8.

Combinations of natural phenomena and plant originated accidents considered in the design are identified in Sections 3.8, 3.9, and 3.10. The importance of the safety functions is identified with the classification system developed by the American Nuclear Society (ANS) and is generally in accordance with ANSI N18.2-1973, Nuclear Safety Criteria for the Design of Stationary Pressurized Water Reactor Plants. This identification and any deviations are included in Section 3.2.

3.1.1.3 Criterion 3 - Fire Protection

"Structures, systems, and components important to safety shall be designed and located to minimize, consistent with other safety requirements, the probability and effect of fires and explosions. Noncombustible and heat resistant materials shall be used wherever practical throughout the unit, particularly in locations such as the containment and control room. Fire detection and fighting systems of appropriate capacity and capability shall be provided and designed to minimize the adverse effects of fires on structures, systems, and components important to safety. Fire fighting systems shall be designed to assure that their rupture or inadvertent operation does not significantly impair the safety capability of the structures, systems, and components [1]."

Discussion

Comanche Peak Nuclear Power Plant is designed to minimize the probability and effect of fires and explosions. Noncombustible and fire resistant materials are used in the Containment Building, in the Control Room, and wherever practical throughout the station. Atmospheric conditions inside the Containment Building and Control Room are not of an explosive nature. Alarm and detection devices are located throughout the station and connected to the annunciation system in the Control Room.

To protect both plant equipment and personnel from fire normal fire protection is provided by water and halon fire suppression systems, hose stations, and portable fire extinguishers. The fire fighting systems are designed to ensure that rupture or inadvertent operation does not significantly impair systems important to safety.

In the design and installation of fire protection equipment, the requirements of the National Fire Protection Association (NFPA), American Nuclear Insurers (ANI), and applicable codes and regulations have been followed. The applicable codes, standards, and regulations used in the design of the Fire Protection System and plant equipment are further discussed in Section 9.5.1 and the Fire Protection Report.

Finally, fire protection and detection system reliability is ensured by periodic tests and inspections.

3.1.1.4 Criterion 4 - Environmental and Dynamic Effects Design Bases

"Structures, systems, and components important to safety shall be designed to accommodate the effects of and to be compatible with the environmental conditions associated with normal operation, maintenance, testing, and postulated accidents, including loss-of-coolant accidents. These structures, systems, and components shall be appropriately protected against dynamic effects, including the effects of missiles, pipe whipping, and discharging fluids, that may result from equipment failures and from events and conditions outside the nuclear power unit. However, the dynamic effects associated with postulated pipe ruptures in nuclear power units may be excluded from the design basis when analyses reviewed and approved by the Commission demonstrate that the probability of fluid system piping rupture is extremely low under basis conditions fluid system piping.[1]"

Discussion

The station's structures, systems, and components important to safety are designed to accommodate the effects of, and to be compatible with, the environmental conditions associated with normal operation, maintenance, testing, and postulated accidents, including loss-of-coolant accident (LOCA). Environmental conditions are described in Section 3.11.

These structures, systems, and components are appropriately protected against dynamic effects, including the effects of missiles, pipe whipping, and discharging fluids, that can result from equipment failures and from events and conditions outside the nuclear power unit.

Details of the design, environmental testing, and construction of these systems, structures, and components are included in Chapters 3, 5, 6, 7, 8, 9 and 10. Evaluation of the performance of safety features is contained in Chapter 15.

The leak before break methodology demonstrates that the probability of fluid system piping rupture is extremely low under conditions consistent with the design basis for the piping. It has been applied to CPNPP Units 1 and 2 to exclude from the design basis the dynamic effects of postulated pipe ruptures in the primary coolant loop piping and 10 inch and larger reactor coolant loop branch lines, as discussed in Sections 3.6B.2.5.1 and 3.6B.2.5. Implementation of this technology eliminates the need for respectively pipe whip restraints and jet impingement barriers. Containment design, emergency core cooling and environmental qualification requirements are not influenced by this modification.

3.1.1.5 Criterion 5 - Sharing of Structures, Systems, and Components

"Structures, systems, and components important to safety shall not be shared between nuclear power units unless it can be shown that such sharing will not significantly impair their ability to perform their safety functions including, in the event of an accident in one unit, an orderly shutdown and cooldown of the remaining unit [1]."

Discussion

The facilities which have shared systems or components are tabulated in Section 1.2 along with references to the appropriate sections containing specific design details. Construction of the second unit will not impair the safety functions of any shared system or component.

The sharing of systems or components does not impair system capability to perform safety functions, e.g., the orderly shutdown and cooldown of one unit in the event of an accident in the other unit.

3.1.2 PROTECTION BY MULTIPLE FISSION PRODUCT BARRIERS

3.1.2.1 Criterion 10 - Reactor Design

"The reactor core and associated coolant, control, and protection systems shall be designed with appropriate margin to assure that specified acceptable fuel design limits are not exceeded during any condition of normal operation, including the effects of anticipated operational occurrences [1]."

Discussion

The reactor core and associated coolant, control, and protection systems are designed with adequate margins to do the following:

1. To preclude significant fuel damage during normal core operation and operational transients (Condition I)[a] or during transient conditions arising from occurrences of moderate frequency (Condition II).[a]

2. To ensure return of the reactor to a safe state following infrequent faults (Condition III)[a] with only a small fraction of fuel rods damaged, although sufficient fuel damage can occur to preclude resumption of operation without considerable outage time.

3. To ensure that the core is intact, with acceptable heat transfer geometry, following transients arising from occurrences of limiting faults (Condition IV).[a]

Chapter 4 discusses the design bases and design evaluation of reactor components, including the fuel, reactor vessel internals, and reactivity control systems. Details of the control and protection systems instrumentation design and logic are discussed in Chapter 7. This information supports the accident analyses of Chapter 15, which show that the acceptable fuel design limits are not exceeded for Condition I and II occurrences.

3.1.2.2 Criterion 11 - Reactor Inherent Protection

“The reactor core and associated coolant systems shall be designed so that in the power operating range the net effect of the prompt inherent nuclear feedback characteristics tends to compensate for a rapid increase in reactivity [1].”

Discussion

When the reactor is critical, prompt compensatory reactivity feedback effects are ensured by the negative fuel temperature effect (Doppler effect) and by the operational limit on moderator temperature coefficient of reactivity. The negative Doppler coefficient of reactivity is ensured by the inherent design using low-enrichment fuel; the limit on moderator temperature coefficient of reactivity is ensured by administratively controlling the dissolved absorber concentration or by burnable poison.

These reactivity coefficients are discussed in Section 4.3.

3.1.2.3 Criterion 12 - Suppression of Reactor Power Oscillations

“The reactor core and associated coolant, control, and protection systems shall be designed to assure that power oscillations which can result in conditions exceeding specified acceptable fuel design limits are not possible or can be reliably and readily detected and suppressed [1].”

(a.) Defined by ANSI N18.2-1973

Discussion

Power oscillations of the fundamental mode are inherently eliminated by the negative power coefficient of reactivity.

In addition, oscillations, due to xenon spatial effects, in the radial, diametral, and azimuthal overtone modes are heavily damped because of the inherent design and because of the negative power coefficient of reactivity.

Also, oscillations, caused by xenon spatial effects, in the axial first overtone mode may occur; however, assurance that fuel design limits are not exceeded by xenon axial oscillations is provided by reactor trip functions using the measured axial power imbalance as an input.

Finally, oscillations, due to xenon spatial effects, in axial modes higher than the first overtone are heavily damped because of the inherent design and because of the negative Doppler coefficient of reactivity.

Xenon stability control is discussed in Section 4.3.

3.1.2.4 Criterion 13 - Instrumentation and Control

“Instrumentation and control shall be provided to monitor variables and systems over their anticipated ranges for normal operation, for anticipated operational occurrences, and for accident conditions as appropriate to assure adequate safety, including those variables and systems that can affect the fission process, the integrity of the reactor core, the reactor coolant pressure boundary, and the containment and its associated systems. Appropriate controls shall be provided to maintain these variables and systems within prescribed operating ranges [1].”

Discussion

To ensure adequate safety, instrumentation and control systems are provided to monitor and control significant variables over their anticipated range for all conditions in the Reactor Core, Reactor Coolant System (RCS), steam and power conversion system, radioactive waste systems, engineered safety features (ESF) systems, and the Containment Building. Parameters that must be provided for operator use under normal operating and accident conditions are indicated in the Control Room in close proximity to the controls which maintain the indicated parameters in the proper range.

The quantity and types of process instrumentation provided ensures safe and orderly operation of all systems over the full design range of the plant. These systems are described in Chapters 6, 7, 8, 9, 10, 11, and 12.

3.1.2.5 Criterion 14 - Reactor Coolant Pressure Boundary

“The reactor coolant pressure boundary shall be designed, fabricated, erected, and tested so as to have an extremely low probability of abnormal leakage, of rapidly propagating failure, and of gross rupture [1].”

Discussion

The RCS pressure boundary is designed to accommodate the system pressures and temperatures attained under the expected modes of plant operation, including anticipated transients, and to maintain the stresses within applicable stress limits (Section 5.2.). Also, reactor coolant pressure boundary (RCPB) materials and selection and fabrication techniques ensure a low probability of gross rupture of significant leakage.

In addition to the loads imposed on the system under normal operating conditions, consideration is also given to abnormal loading conditions, such as seismic and pipe rupture, which are discussed in Sections 3.6 and 3.7.

The leak before break methodology demonstrates that the probability of rupturing primary coolant piping is extremely low under design basis conditions. It has been applied to CPNPP Units 1 and 2 to exclude from the design basis the dynamic effects of postulated ruptures in the primary coolant loop piping, as discussed in Section 3.6B.2.5.1. Implementation of this technology eliminates the need for primary coolant loop piping whip restraints and jet impingement barriers. Containment design, emergency core cooling and environmental qualification requirements are not influenced by this modification.

The system is protected from overpressure by means of pressure-relieving devices as required by applicable codes.

In conclusion, the RCS boundary has provisions for inspection, testing, and surveillance of critical areas to assess the structural and leaktight integrity (Section 5.2). For the reactor vessel, a material surveillance program conforming to applicable codes is provided (Section 5.3).

3.1.2.6 Criterion 15 - Reactor Coolant System Design

“The reactor coolant system and associated auxiliary, control, and protection systems shall be designed with sufficient margin to assure that the design conditions of the reactor coolant pressure boundary are not exceeded during any condition of normal operation, including anticipated operational occurrences [1].”

Discussion

The design pressure and temperature for each component in the RCS and associated auxiliary, control, and protection systems are selected to be above the maximum coolant pressure and temperature under all normal and anticipated transient load conditions.

In addition, RCPB components achieve a large margin of safety by the use of proven American Society of Mechanical Engineers (ASME) materials and design codes, use of proven fabrication techniques, nondestructive shop testing, and of integrated hydrostatic testing of assembled components.

Chapter 5 discusses the RCS design.

3.1.2.7 Criterion 16 - Containment Design

“Reactor containment and associated systems shall be provided to establish an essentially leak-tight barrier against the uncontrolled release of radioactivity to the environment and to assure that the containment design conditions important to safety are not exceeded for as long as postulated accident conditions require [1].”

Discussion

A steel-lined, reinforced concrete containment structure encloses the entire RCS and is designed to withstand the pressures and temperatures resulting from a spectrum of postulated LOCAs and secondary system breaks.

The Emergency Core Cooling System cools the reactor core and limits the release of radioactive materials to the environment.

Next, to ensure its integrity, the Containment Spray System is incorporated in the containment design.

The Containment Spray System is designed to function after a LOCA to reduce the pressure inside the containment to near atmospheric pressure and to remove fission product activity from the containment atmosphere.

To sum up, the Containment structure and ESF systems are designed to safely sustain internal and external environmental conditions that may reasonably be expected to occur during the life of the plant, including both short- and long-term effects following a LOCA (See Sections 6.2, 6.5, 15.6, and 3.8.1).

3.1.2.8 Criterion 17 - Electric Power Systems

“An onsite electric power system and an offsite electric power system shall be provided to permit functioning of structures, systems, and components important to safety. The safety function for each system (assuming the other system is not functioning) shall be to provide sufficient capacity and capability to assure that (1) specified acceptable fuel design limits and design conditions of the reactor coolant pressure boundary are not exceeded as a result of anticipated operational occurrences, and (2) the core is cooled and containment integrity and other vital functions are maintained in the event of postulated accidents.

“The onsite electric power sources, including the batteries, and the onsite electrical distribution system, shall have sufficient independence, redundancy, and testability to perform their safety functions, assuming a single failure.

“Electric power from the transmission network to the onsite electric distribution system shall be supplied by two physically independent circuits (not necessarily on separate rights of way) designed and located so as to minimize to the extent practical the likelihood of their simultaneous failure under operating and postulated accident and environmental conditions. A switchyard common to both circuits is acceptable. Each of these circuits shall be designed to be available in sufficient time following a loss of all onsite alternating current power supplies and the other offsite electrical power circuit, to assure that specified acceptable fuel design limits and design conditions of the reactor coolant pressure boundary are not exceeded. One of these circuits

shall be designed to be available within a few seconds following a loss-of-coolant accident to assure that core cooling, containment integrity, and other vital safety functions are maintained.

"Provisions shall be included to minimize the probability of losing electric power from any of the remaining supplies as a result of, or coincident with, the loss of power generated by the nuclear power unit, the loss of power from the transmission network, or the loss of power from the onsite electrical power supplies [1]."

Discussion

To ensure the functioning of safety-related systems, an onsite electrical power system and an offsite electrical power system are provided and are designed with adequate independence, capacity, redundancy, and testability.

Independence is provided for both systems by physical separation of components and cables to minimize vulnerability of redundant systems to single credible accidents. For details of separation, see Chapter 8.

Offsite power is provided to the safety-related systems through the startup transformers. The startup transformers are independent of each other and are each capable of supplying the Class 1E systems of each unit. One transformer is connected to the 345 kilovolts (kV) Switchyard and the other to the 138 kV system, so that a single component failure will not prevent the safety-related systems from performing their function (Section 8.2).

The onsite AC source of electrical power consists of four diesel generators, one connected and used exclusively for Unit 1 train A, one connected and used exclusively for Unit 1 train B, one connected and used exclusively for Unit 2 train A, and one connected and used exclusively for Unit 2 train B. One diesel generator is capable of supplying sufficient power for the operation of the minimum safety features required for the unit during a postulated LOCA. However, during a postulated LOCA, both diesel generators start automatically, connect to the two safety features buses of the unit, and sequentially start the safety-related loads.

The two safety features buses and their associated diesel generators are so arranged that a failure of a single component will not prevent the power supply systems from performing their function (Section 8.3).

In conclusion, for each unit, two DC battery systems are provided in physically separated rooms; each one is adequate to supply the DC control power required for the engineered safety features. Failure of a single component in this system does not impair control of the minimum safety features required to maintain each unit in a safe condition. See Section 8.3 for failure mode analysis.

3.1.2.9 Criterion 18 - Inspection and Testing of Electric Power System

"Electric power systems important to safety shall be designed to permit appropriate periodic inspection and testing of important areas and features, such as wiring, insulation, connections, and switchboards, to assess the continuity of the systems and the condition of their components. The systems shall be designed with a capability to test periodically (1) the operability and functional performance of the components of the systems, such as onsite power sources, relays, switches, and buses and (2) the operability of the systems as a whole and, under conditions as

close to design as practical, the full operational sequence that brings the systems into operation, including operation of applicable portions of the protection system and the transfer of power among the nuclear power unit, the offsite power system, and the onsite power system [1]."

Discussion

All Class 1E power systems are designed to permit periodic inspection and testing. The testing procedure simulates a loss of bus voltage to start a diesel generator and connect it to the bus. Full load testing of the diesel generator is performed by manually synchronizing the generator to the normal power supply. Under conditions as close to design as practical, these tests, therefore, prove the capability of the power supply system to assess the continuity of the systems and the conditions of components.

Inspections and tests which constitute compliance with this criterion are included in Section 8.3.

3.1.2.10 Criterion 19 Control Room

"A control room shall be provided from which actions can be taken to operate the nuclear power unit safely under normal conditions and to maintain it in a safe condition under accident conditions, including loss-of-coolant accidents. Adequate radiation protection shall be provided to permit access and occupancy of the control room under accident conditions without personnel receiving radiation exposures in excess of 5 rem whole body, or its equivalent to any part of the body, for the duration of the accident."

"Equipment at appropriate locations outside the control room shall be provided (1) with a design capability for prompt hot shutdown of the reactor, including necessary instrumentation and controls to maintain the unit in a safe condition during hot shutdown, and (2) with a potential capability for subsequent cold shutdown of the reactor through the use of suitable procedures [1]."

Discussion

Safe occupancy of the Control Room during abnormal conditions is provided for in the design. The Control Room is in a seismic Category I structure (See Figures 1.2-33 and 13.5-1). Adequate shielding is provided for the Control Room in the event of a design basis accident (DBA), as detailed in Sections 12.1 and 15.6. The Control Room Air-Conditioning System features redundant equipment, and radiation and smoke detectors, with appropriate alarms and interlocks. Provisions are made for Control Room air to be recirculated through high-efficiency particulate air (HEPA) and charcoal filters, as discussed in Sections 6.4, 6.5 and 9.4.

The Control Room is continuously occupied by qualified operating personnel under all operating and accident conditions.

In the unlikely event that access to the Control Room is restricted, the hot shutdown panel, local control stations, or manual operation of critical components can be used to effect hot shutdown from outside the Control Room for an extended period.

Before evacuation takes place the reactor can be manually tripped and neutron level and control rod position can be verified. By use of appropriate procedures and equipment, the unit can also be brought to cold shutdown conditions. (See Section 7.4.)

3.1.3 PROTECTION AND REACTIVITY CONTROL SYSTEMS

3.1.3.1 Criterion 20 - Protection System Functions

"The protection systems shall be designed (1) to initiate automatically the operation of appropriate systems, including the reactivity control systems, and to assure that specified acceptable fuel design limits are not exceeded as a result of anticipated operational occurrences and (2) to sense accident conditions and to initiate the operation of systems and components important to safety [1]."

Discussion

A fully automatic protection system with appropriate redundant channels is provided to cope with transients where insufficient time is available for manual corrective action. The design basis for all protection systems is in accordance with the intent of Institute of Electrical and Electronic Engineers (IEEE) 279-1971 and IEEE 379-1972. The Reactor Protection System automatically initiates a reactor trip when any variable monitored by the system or combination of monitored variables exceeds the normal operating range. Set points are designed to provide an envelope of safe operating conditions with adequate margin for uncertainties to ensure that fuel design limits are not exceeded.

Reactor trip is initiated by removing power to the control rod drive mechanisms (CRDM) of all full-length rod cluster control assemblies (RCCA). This causes the rods to insert by the force of gravity, rapidly reducing the reactor power output. The response and adequacy of the protection system has been verified by analysis of anticipated transients.

Refer to Chapter 7, Instrumentation and Controls, for additional information regarding actuating devices to the protection system.

The ESF Actuation System automatically initiates emergency core cooling and other safeguards functions by sensing accident conditions using redundant analog channels measuring diverse variables. In addition, manual actuation of safeguards can be performed where ample time is available for operator action. In either case, the ESF Actuation System automatically trips the reactor on manual or automatic safety injection signal generation.

3.1.3.2 Criterion 21 - Protection Systems Reliability and Testability

"The protection system shall be designed for high functional reliability and inservice testability commensurate with the safety functions to be performed. Redundancy and independence designed into the protection system shall be sufficient to assure that (1) no single failure results in loss of the protection function and (2) removal from service of any component or channel does not result in loss of the required minimum redundancy unless the acceptable reliability of operation of the protection system can be otherwise demonstrated. The protection system shall be designed to permit periodic testing of its functioning when the reactor is in operation, including a capability to test channels independently to determine failures and losses of redundancy that may have occurred [1]."

Discussion

The protection system is designed for high functional reliability and inservice testability. It is designed with sufficient redundancy and independence to permit acceptable reliability of operation. System design also includes the capability to perform periodic testing of channels independently while the reactor is in operation.

Compliance with this criterion is discussed in detail in Sections 7.2.2.2.3 and 7.3.2.2.5.

3.1.3.3 Criterion 22 - Protection System Independence

"The protection system shall be designed to assure that the effects of natural phenomena, and of normal operating, maintenance, testing, and postulated accident conditions on redundant channels do not result in loss of the protection function, or shall be demonstrated to be acceptable on some other defined basis. Design techniques, such as functional diversity or diversity in component design and principles of operation shall be used to the extent practical to prevent loss of the protection function [1]."

Discussion

Protection system components are designed and arranged so that there is no loss of safety function in the environment accompanying any emergency situation in which the components are required to function. Various means are used to accomplish this. Functional diversity has been designed into the system. The extent of this functional diversity has been evaluated for a wide variety of postulated accidents. Also, diverse protection functions will automatically terminate an accident before intolerable consequences can occur.

Automatic reactor trips are based upon neutron flux measurements, reactor coolant loop (RCL) temperature measurements, pressurizer pressure and level measurements, and reactor coolant pump power underfrequency and undervoltage measurements. Trips can also be initiated manually or by safety injection signal (Section 7.2).

With regard to the ESF Actuation System, a LOCA safety injection signal can be obtained manually or by automatic initiation from two diverse sets of signals:

1. Low pressurizer pressure

2. High containment pressure

For a steam line break accident, diversity of safety injection signal for automatic actuation is provided by:

1. Low compensated steamline pressure

2. High containment pressure (for a steam line break inside the Containment Building)

For information regarding the independence of the protection system logic, see Section 7.3.

High quality components, conservative design, applicable quality control, inspection, calibration, and tests are used to guard against common mode failure. Qualification testing is performed on

the various safety systems to demonstrate functional operation at normal and post-accident conditions of temperature, humidity, pressure, chemistry, and radiation for specified periods, if required. See Section 3.11 for further details. Typical protection system equipment is subjected to tests under simulated seismic conditions using conservatively large accelerations and applicable frequencies. The test results indicate no loss of the protection function. See Section 3.10 for further details.

3.1.3.4 Criterion 23 - Protection System Failure Modes

"The protection system shall be designed to fail into a safe state or into a state demonstrated to be acceptable on some other defined basis if conditions such as disconnection of the system, loss of energy (e.g., electric power, instrument air), or postulated adverse environments (e.g., extreme heat or cold, fire, pressure, steam, water, and radiation) are experienced [1]."

Discussion

The protection system is designed with due consideration of the most probable failure modes of the components under various perturbations of the environment and energy sources. Each reactor trip channel is designed on the de-energize-to-trip principle so that loss of power, disconnection, open-channel faults, and the majority of internal channel short-circuit faults cause the channel to go into its tripped mode.

The protection system is discussed in Sections 7.2 and 7.3.

3.1.3.5 Criterion 24 - Separation of Protection and Control Systems

"The protection system shall be separated from control systems to the extent that failure of a single control system component or channel, or failure or removal from service of any single protection system component or channel which is common to the control and protection systems leaves intact a system satisfying all reliability, redundancy, and independence requirements of the protection system. Interconnection of the protection and control systems shall be limited so as to assure that safety is not significantly impaired [1]."

Discussion

The protection system is separate and distinct from the control systems. Control systems may be dependent on the protection system because control signals are derived from protection system measurements where applicable. These signals are transferred to the control system by isolation amplifiers, which are classified as protection components. The adequacy of system isolation has been verified by testing under conditions of postulated credible faults. The failure of a single control system component or channel, or failure or removal from service of any single protection system component or channel which is common to the control and protection systems, leaves intact a system satisfying all reliability, redundancy, and independence requirements of the protection system. See Chapter 7 for details. Distinction between channel and train is made in this discussion. The removal of a train from service is allowed only during testing of the train.

3.1.3.6 Criterion 25 - Protection System Requirements For Reactivity Control Malfunctions

"The protection system shall be designed to assure that specified acceptable fuel design limits are not exceeded for any single malfunction of the reactivity control systems, such as accidental withdrawal (not ejection or dropout) of control rods [1]."

Discussion

The protection system is designed to limit reactivity transients so that fuel design limits are not exceeded. Reactor shutdown by full-length rod insertion is completely independent of the normal control function since the trip breakers interrupt power to the rod mechanisms regardless of existing control signals. In the postulated accidental withdrawal (assumed to be initiated by a control malfunction), flux, temperature, pressure, level, and flow signals are independently generated. Any of these signals (trip demands) can operate the breakers to trip the reactor.

Analyses of the effects of possible malfunctions are discussed in Chapter 15. These analyses show that for postulated dilution during refueling, cold shutdown, hot standby, startup, or manual or automatic operation at power, the operator has ample time to determine the cause of dilution, and to initiate reboration before the shutdown margin is lost. The analyses also show that acceptable fuel damage limits are not exceeded even in the event of a single malfunction of either system.

3.1.3.7 Criterion 26 - Reactivity Control System Redundancy and Capability

"Two independent reactivity control systems of different design principles shall be provided. One of the systems shall use control rods, preferably including a positive means for inserting the rods, and shall be capable of reliably controlling reactivity changes to assure that under conditions of normal operation, including anticipated operational occurrences, and with appropriate margin for malfunctions such as stuck rods, specified acceptable fuel design limits are not exceeded. The second reactivity control system shall be capable of reliably controlling the rate of reactivity changes resulting from planned, normal power changes (including xenon burnout) to assure acceptable fuel design limits are not exceeded. One of the systems shall be capable of holding the reactor core subcritical under cold conditions [1]."

Discussion

Two reactivity control methods are provided. These are rod control cluster assemblies (RCCA) and chemical shim (boric acid). The RCCAs are inserted into the core by the force of gravity.

During operation the shutdown rod banks are fully withdrawn. The full-length control rod system automatically maintains a programmed average reactor temperature compensating for reactivity effects associated with scheduled and transient load changes. The shutdown rod banks, along with the full-length control banks, are designed to shut down the reactor with adequate margin under conditions of normal operation and anticipated operational occurrences, thereby ensuring that specified fuel design limits are not exceeded. The most restrictive period in core life is assumed in all analyses and the most reactive rod cluster is assumed to be in the fully withdrawn position.

The boron system maintains the reactor in the cold shutdown state independent of the position of the control rods and can compensate for xenon burnout transients.

Details of the construction of the RCCA are presented in Chapter 4; the operation is discussed in Chapter 7. The means of controlling the boric acid concentration are described in Chapter 9; performance analyses under accident conditions are included in Chapter 15.

3.1.3.8 Criterion 27 - Combined Reactivity Control Systems Capability

"The reactivity control systems shall be designed to have a combined capability, in conjunction with poison addition by the emergency core cooling system, of reliably controlling reactivity changes to assure that under postulated accident conditions and with appropriate margin for stuck rods the capability to cool the core is maintained [1]."

Discussion

The facility is provided with means of making the core subcritical and maintaining it at that level under any anticipated conditions and with an appropriate margin for contingencies. These means are discussed in detail in Chapters 4 and 9. Combined use of the rod cluster control assemblies and the chemical shim permits the necessary shutdown margin to be maintained during long-term xenon decay and plant cooldown. Upon trip for this determination, the single highest worth control cluster is assumed to be stuck full-out upon trip.

3.1.3.9 Criterion 28 - Reactivity Limits

"The reactivity control systems shall be designed with appropriate limits on the potential amount and rate of reactivity increase to assure that the effects of postulated reactivity accidents can neither (1) result in damage to the reactor coolant pressure boundary greater than limited local yielding nor (2) sufficiently disturb the core, its support structures or other reactor pressure vessel internals to impair significantly the capability to cool the core. These postulated reactivity accidents shall include consideration of rod ejection (unless prevented by positive means), rod dropout, steam line rupture, changes in reactor coolant temperature and pressure, and cold water addition [1]."

Discussion

The maximum reactivity worth of control rods and the maximum rates of reactivity insertion employing control rods are limited to values that prevent rupture of the RCS boundary or disruptions of the core or vessel internals to a degree that could impair the effectiveness of emergency core cooling.

The maximum positive reactivity insertion rates for the withdrawal of RCCA and the dilution of the boric acid in the RCS are limited by the physical design characteristics of the RCCA and of the Chemical and Volume Control System (CVCS). Technical specifications on shutdown margin and on RCCA insertion limits and bank overlaps as functions of power provide additional assurance that the consequences of the postulated accidents are no more severe than those presented in the analyses of Chapter 15. Reactivity insertion rates, dilution, and withdrawal limits are also discussed in Section 4.3. The capability of the CVCS to avoid an inadvertent excessive rate of boron dilution is discussed in Chapter 15.

Assurance of core cooling capability following Condition IV accidents, such as rod ejections, steam line break, and similar accidents, is given by keeping the RCPB stresses within faulted condition limits as specified by applicable ASME codes. Structural deformations are checked also and limited to values that do not jeopardize the operation of necessary safety features.

3.1.3.10 Criterion 29 - Protection Against Anticipated Operational Occurrences

"The protection and reactivity control systems shall be designed to assure an extremely high probability of accomplishing their safety functions in the event of anticipated operational occurrences [1]."

Discussion

The protection and reactivity control systems are designed to ensure extremely high probability of performing their required safety functions in any anticipated operational occurrences. Likely failure modes of system components are designed to be safe modes. Equipment used in these systems is designed, constructed, operated, and maintained with a high level of reliability. In addition, loss of power to the protection system results in a reactor trip. Details of system design are covered in Chapter 7; also refer to the discussions of GDC 20 through 25.

3.1.4 FLUID SYSTEMS

3.1.4.1 Criterion 30 - Quality of Reactor Coolant Pressure Boundary

"Components which are part of the reactor coolant pressure boundary shall be designed, fabricated, erected, and tested to the highest quality standards practical. Means shall be provided for detecting and, to the extent practical, identifying the location of the source of reactor coolant leakage [1]."

Discussion

RCPB components are designed, fabricated, inspected, and tested in conformance with ASME Boiler and Pressure Vessel (B&PV) Code, Section III. All components are classified according to ANSI N18.2-1973 except as noted in Sections 3.2 and 5.2 and are accorded the quality measures appropriate to the classification. The design bases and evaluations of RCPB components are discussed in Chapter 5.

Leakage from components is detected by an increase in the amount of makeup of water required to maintain a normal level in the pressurizer.

The reactor vessel closure joint is provided with a temperature-monitored leakoff between double gaskets. Leakage into the containment is drained to the Containment Building sump.

Leakage is also detected by measuring both the airborne activity and the rate at which condensate is drained from the Containment Building recirculation units. Monitoring the inventory of reactor coolant in the system at the pressurizer, volume control tank, and coolant drain collection tanks makes available an accurate indication of integrated leakage. The RCPB leakage detection system is discussed in Section 5.2.5.

3.1.4.2 Criterion 31 - Fracture Prevention of Reactor Coolant Pressure Boundary

"The reactor coolant pressure boundary shall be designed with sufficient margin to assure that when stressed under operating, maintenance, testing, and postulated accident conditions (1) the boundary behaves in a nonbrittle manner and (2) the probability of rapidly propagating fracture is minimized. The design shall reflect consideration of service temperatures and other conditions of the boundary material under operating, maintenance, testing, and postulated accident conditions and the uncertainties in determining (1) material properties, (2) the effects of irradiation on material properties, (3) residual, steady state, and transient stresses, and (4) size of flaws [1]."

Discussion

Close control is maintained over material selection and fabrication for the RCS to ensure that the boundary behaves in a nonbrittle manner. Those RCS materials which are exposed to the coolant are corrosion resistant, stainless steel, or Inconel. The reference temperature (RT_{NDT}) of the reactor vessel structural steel is established by Charpy V-notch and drop weight tests in accordance with 10 CFR Part 50, Appendix G.

As part of the reactor vessel specification, certain requirements which are not specified by the applicable ASME codes are performed, as follows:

1. Ultrasonic Testing

   In addition to code requirements, the performance of a 100 percent volumetric ultrasonic test of reactor vessel plate for shear wave and a post-hydro-test ultrasonic map of all welds in the pressure vessel are required. Cladding bond ultrasonic inspection to more restrictive requirements than those specified in the codes is also required to preclude interpretation problems during inservice inspection.

2. Radiation Surveillance Program

   In the surveillance programs, the evaluation of the radiation damage is based on pre-irradiation and post-irradiation testing of Charpy V-notch and tensile specimens. These programs evaluate the effect of radiation on the fracture toughness of reactor vessel steels based on the measured change in reference transition temperature and fracture mechanics measurements. These measurements are performed in accordance with American Society Testing Material (ASTM) E 185-1982, Recommended Practice for Surveillance Tests for Nuclear Reactor Vessels, and the requirements of 10 CFR Part 50, Appendix H.

3. Material chemistry (copper, nickel, phosphorous, sulfur, and vanadium) of the reactor vessel core region is controlled to reduce sensitivity to embrittlement, which is caused by irradiation over the life of the plant.

The fabrication and quality control techniques used in the fabrication of the RCS are equivalent to those used for the reactor vessel. The inspections of reactor vessel, pressurizer, piping, pumps, and steam generator are governed by the requirements of ASME Codes (see Chapter 5.0).

Allowable pressure-temperature relationships for plant heatup and cooldown rates are calculated using methods derived from the ASME B&PV Code, Section III, Appendix G, Protection Against Non-Ductile Failure. The approach specifies that allowed stress intensity factors for all vessel operating conditions shall not exceed the reference stress intensity factor (KIR) for the metal temperature at any time. Operating specifications include conservative margins for predicted changes in the material (RT_{NDT}) due to irradiation.

3.1.4.3 Criterion 32 - Inspection of Reactor Coolant Pressure Boundary

"Components which are part of the reactor coolant pressure boundary shall be designed to permit (1) periodic inspection and testing of important areas and features to assess their structural and leaktight integrity, and (2) an appropriate material surveillance program for the reactor pressure vessel [1]."

Discussion

The design of the RCPB provides the capability for accessibility during service life to the entire internal surfaces of the reactor vessel, certain external zones of the vessel (including the nozzle to reactor coolant piping welds and the top and bottom heads), and external surfaces of the reactor coolant piping, except for the area of pipe within the primary shielding concrete. The inspection capability complements the leakage detection systems in assessing pressure boundary component integrity. The RCPB is periodically inspected under the provisions of ASME B&PV Code, Section XI.

Monitoring of changes in the fracture toughness properties of the reactor vessel core region plates forging, weldments, and associated heat-treated zones are performed in accordance with 10 CFR Part 50, Appendix H, Reactor Vessel Material Surveillance Program Requirements. Samples of reactor vessel plate materials are retained and cataloged in case future engineering development shows the need for further testing.

The material properties surveillance program includes not only the conventional tensile and impact tests, but also fracture mechanics specimens. The observed shifts in RT_{NDT} of the core region materials with irradiation are used to confirm the allowable limits calculated for all operational transients.

3.1.4.4 Criterion 33 - Reactor Coolant Makeup

"A system to supply reactor coolant makeup for protection against small breaks in the reactor coolant pressure boundary shall be provided. The system safety function shall be to assure that specified acceptable fuel design limits are not exceeded as a result of reactor coolant loss due to leakage from the reactor coolant pressure boundary and rupture of small piping or other small components which are part of the boundary. The system shall be designed to assure that for onsite electric power system operation (assuming offsite power is not available) and for offsite electric power system operation (assuming onsite power is not available) the system safety function can be accomplished using the piping, pumps, and valves used to maintain coolant inventory during reactor operation [1]."

Discussion

The CVCS provides a means of reactor coolant makeup and adjustment of the boric acid concentration. Makeup is added automatically if the level in the volume control tank falls below the preset level. The high pressure centrifugal charging pumps provided are capable of supplying the required makeup and reactor coolant seal injection flow when power is available from either onsite or offsite electric power systems. These pumps also serve as high head safety injection pumps. Functional reliability is ensured by the provision of standby components ensuring a safe response to probable modes of failure. Details of system design are included in Sections 6.3 and 9.3; details of the electric power system are included in Chapter 8.

3.1.4.5 Criterion 34 - Residual Heat Removal

"A system to remove residual heat shall be provided. The system safety function shall be to transfer fission product decay heat and other residual heat from the reactor core at a rate such that specified acceptable fuel design limits and the design conditions of the reactor coolant pressure boundary are not exceeded.

"Suitable redundancy in components and features, and suitable interconnections, leak detection, and isolation capabilities shall be provided to assure that for onsite electric power system operation (assuming offsite power is not available) and for offsite electric power system operation (assuming onsite power is not available) the system safety function can be accomplished, assuming a single failure [1]."

Discussion

The Residual Heat Removal (RHR) System in conjunction with the steam and power conversion system is designed to transfer the fission production decay heat and other residual heat from the reactor core within acceptable limits. The Auxiliary Feedwater System provides backup for the steam and power conversion system in this function. The Auxiliary Feedwater System is described in Section 10.4.9.

The crossover from the steam and power conversion system to the RHR System occurs at approximately 350 degrees Fahrenheit (°F) and 425 pounds per square inch gauge (psig).

Suitable redundancy at temperatures below approximately 350°F is accomplished with the two RHR pumps (located in separate compartments with means available for draining and monitoring of leakage), the two heat exchangers, and the associated piping, cabling, and electric power sources. The RHR System is capable of operating on either onsite or offsite electrical power systems.

Suitable redundancy at temperatures above approximately 350°F is provided by the four steam generators and associated piping systems.

Details of system design are in Section 5.4.7.

3.1.4.6 Criterion 35 - Emergency Core Cooling

"A system to provide abundant emergency core cooling shall be provided. The system safety function shall be to transfer heat from the reactor core following any loss of reactor coolant at a

rate such that (1) fuel and clad damage that could interfere with continued effective core cooling is prevented and (2) clad metal water reaction is limited to negligible amounts.

“Suitable redundancy in components and features, and suitable interconnections, leak detection, isolation, and containment capabilities shall be provided to assure that for onsite electrical power system operation (assuming offsite power is not available) and for offsite electrical power system operation (assuming onsite power is not available) the system safety function can be accomplished, assuming a single failure [1].”

Discussion

An Emergency Core Cooling System (ECCS) is provided to cope with any LOCA in the plant design basis. Abundant cooling water is available in an emergency to transfer heat from the core at a rate sufficient to maintain the core in a coolable geometry and to ensure that clad metal-water reaction is limited to less than 1 percent. Adequate design provisions are made to ensure performance of the required safety functions even with a single failure.

Details of the capability of the systems are included in Section 6.3. An evaluation of the adequacy of the system functions is included in Chapter 15. Performance evaluations are conducted in accordance with 10 CFR Part 50, Section 50.46, and Appendix K.

3.1.4.7 Criterion 36 - Inspection of Emergency Core Cooling System

“The emergency core cooling system shall be designed to permit appropriate periodic inspection of important components, such as spray rings in the reactor pressure vessel, water injection nozzles, and piping, to assure the integrity and capability of the system [1].”

Discussion

Design provisions facilitate access to the critical parts of the injection nozzles, pipes, and valves for visual inspection and for nondestructive inspection where such techniques are desirable and appropriate. The design is in accordance with the requirements of ASME B&PV Code, Section XI, Subarticle IWA-1500.

The components outside the Containment Building are accessible for leaktightness inspection during operation of the reactor.

Details of the inspection program of the ECCS are discussed in Section 6.3 and in the technical specifications.

3.1.4.8 Criterion 37 - Testing of Emergency Core Cooling System

“The emergency core cooling system shall be designed to permit appropriate periodic pressure and functional testing to assure (1) the structural and leaktight integrity of its components, (2) the operability and performance of the active components of the system, and (3) the operability of the system as a whole and, under conditions as close to design as practical, the performance of the full operational sequence that brings the system into operation, including operation of applicable portions of the protection system, the transfer between normal and emergency power sources, and the operation of the associated cooling water system [1].”

Discussion

Each active component of the ECCS can be individually actuated on the normal power source and can be transferred to the emergency power source at any time during appropriate plant periodic tests.

Tests can also be performed during shutdown to demonstrate proper automatic operation of the ECCS.

The details of the ECCS testing program are included in Section 6.3.

3.1.4.9 Criterion 38 - Containment Heat Removal

"A system to remove heat from the reactor containment shall be provided. The system safety function shall be to reduce rapidly, consistent with the functioning of other associated systems, the containment pressure and temperature following any loss-of-coolant accident and maintain them at acceptably low levels.

"Suitable redundancy in components and features, and suitable interconnections, leak detection, isolation, and containment capabilities shall be provided to assure that for onsite electric power system operation (assuming offsite power is not available) and for offsite electric power system operation (assuming onsite power is not available) the system safety function can be accomplished, assuming a single failure [1]."

Discussion

Two separate containment spray recirculation trains described in Section 6.2.2, each with 100 percent capacity, remove heat from the Containment Building following certain design basis accidents. Each train contains two separate pumps, one heat exchanger, and seven spray headers, and each system is fed from its individual electrical Class 1E bus. Each Class 1E bus is connected to a separate offsite power source and is also connected to its individual onsite power source as described in Section 8.3. Containment isolation valves separate all components from the containment penetrations.

Finally, the containment heat removal system is designed to ensure that the failure of any single active component, assuming the availability of either onsite or offsite power exclusively, does not prevent the system from accomplishing its planned safety function.

3.1.4.10 Criterion 39 - Inspection of Containment Heat Removal System

"The containment heat removal system shall be designed to permit appropriate periodic inspection of important components, such as the torus, sumps, spray nozzles, and piping to assure the integrity and capability of the system.[1]"

Discussion

The containment heat removal system design permits appropriate periodic inspection of the components as described in Section 6.2.2. The essential equipment of the Containment Spray System is outside the Containment Building, except for risers, distribution header piping, spray nozzles, and the containment sump.

The containment sump, spray piping, and nozzles can be inspected during shutdowns. Those portions of the containment spray suction piping between the sump and the Refueling Water Storage Tank as well as associated equipment outside the Containment Building are accessible for inspection.

3.1.4.11 Criterion 40 - Testing of Containment Heat Removal System

"The containment heat removal system shall be designed to permit appropriate periodic pressure and functional testing to assure (1) the structural and leaktight integrity of its components, (2) the operability and performance of the active components of the system, and (3) the operability of the system as a whole, and, under conditions as close to the design as practical, the performance of the full operational sequence that brings the system into operation, including operation of applicable portions of the protection system, the transfer between normal and emergency power sources, and the operation of the associated cooling water system [1]."

Discussion

System piping, valves, pumps, heat exchangers, and other components of the containment heat removal system are arranged so that each component can be tested periodically for operability, including transfer to emergency power sources. The delivery capability of the Containment Spray System is tested periodically, to the extent practical, up to the last isolation valve before the spray nozzles. The delivery capability of the spray nozzles is tested periodically by blowing low pressure air through the nozzles and verifying the flow. The Containment Spray Systems are tested for operational sequence as close to the design as practical (see Section 6.2.2).

3.1.4.12 Criterion 41 - Containment Atmosphere Cleanup

"Systems to control fission products, hydrogen, oxygen, and other substances which may be released into the reactor containment shall be provided as necessary to reduce, consistent with the functioning of other associated systems, the concentration and quantity of fission products released to the environment following postulated accidents, and to control the concentration of hydrogen or oxygen and other substances in the containment atmosphere following postulated accidents to assure that containment integrity is maintained.

"Each system shall have suitable redundancy in components and features, and suitable interconnections, leak detection, isolation, and containment capabilities to assure that for onsite electrical power system operation (assuming offsite power is not available) and for offsite electric power system operation (assuming onsite power is not available) its safety function can be accomplished, assuming a single failure [1]."

Discussion

The Containment Spray System includes a chemical additive subsystem using a basic sodium hydroxide solution to enhance post-accident fission product removal efficiency as described in Section 6.5.2. The unit is equipped with two independent spray systems supplied from separate buses, as described in Chapter 8, and either system alone can provide the iodine removal capacity for which credit is taken as described in Section 15.6.

Post-accident combustible gas control is ensured by a Hydrogen Purge System described in Section 6.2.5.

3.1.4.13 Criterion 42 - Inspection of Containment Atmosphere Cleanup Systems

"The containment atmosphere cleanup systems shall be designed to permit appropriate periodic inspection of important components, such as filter frames, ducts, and piping to assure the integrity and capability of the systems [1]."

Discussion

The containment atmosphere cleanup systems are designed and located so that they can be inspected periodically, as detailed in Section 6.5.

3.1.4.14 Criterion 43 - Testing of Containment Atmosphere Cleanup Systems

"The containment atmosphere cleanup systems shall be designed to permit appropriate periodic pressure and functional testing to assure (1) the structural and leaktight integrity of its components, (2) the operability and performance of the active components of the systems such as fans, filters, dampers, pumps, and valves and (3) the operability of the systems as a whole and, under conditions as close to design as practical, the performance of the full operational sequence that brings the systems into operation, including operation of applicable portions of the protection system, the transfer between normal and emergency power sources, and the operation of associated systems [1]."

Discussion

The containment atmosphere cleanup system can be tested as follows:

The operation of the spray pumps can be tested by recirculation through a test line to the Refueling Water Storage Tank (RWST). The system valves can be operated through their full travel, and the system can be checked for leaktightness during testing. See Section 6.5 for details. Power transfer is described in Chapter 8.

3.1.4.15 Criterion 44 - Cooling Water

"A system to transfer heat from structures, systems, and components important to safety to an ultimate heat sink shall be provided. The system safety function shall be to transfer the combined heat load of these structures, systems, and components under normal operating and accident conditions.

"Suitable redundancy in components and features, and suitable interconnections, leak detection, and isolation capabilities shall be provided to assure that for onsite electrical power system operation (assuming offsite power is not available) and for offsite electrical power system operation (assuming onsite power is not available) the system safety function can be accomplished, assuming a single failure [1]."

Discussion

The cooling water system for safety-related functions consists of the Station Service Water System (SSWS) and the Component Cooling Water System (CCWS).

The SSWS removes heat from the component cooling heat exchangers.

The CCWS is a closed system. It is designed to remove residual heat from the RCS, cool the letdown flow to the CVCS, cool safety-feature heat loads, and dissipate rejected heat from various plant components. The ultimate heat sink used to dissipate rejected heat from the reactor facility during normal and emergency shutdown conditions is the Safe Shutdown Impoundment (SSI).

Both the SWS and CCWS have two flow loops with redundant pumps, heat exchangers, and piping arrangements. The system is designed to meet the required safety function so that no single failure impairs cooling of essential equipment. See Section 9.2 for details.

The ultimate heat sink has the capability to ensure either the simultaneous shutdown and cooldown of both units or the shutdown and cooldown of one unit simultaneously with the dissipation of post- accident heat from the other unit. Both systems are operable from either the offsite power system or the onsite diesel generators.

3.1.4.16 Criterion 45 - Inspection of Cooling Water System

“The cooling water system shall be designed to permit appropriate periodic inspection of important components, such as heat exchangers and piping, to assure the integrity and capability of the system [1].”

Discussion

The essential components are located in accessible areas and are interchanged periodically to enable inspection to be performed. Appropriate design and layout features to allow periodic visual inspection are also incorporated. The system (the Station Service Water System and the Component Cooling Water System), therefore, can be inspected completely to find and correct incipient malfunctions. See Section 9.2 for details.

3.1.4.17 Criterion 46 - Testing of Cooling Water System

“The cooling water system shall be designed to permit appropriate periodic pressure and functional testing to assure (1) the structural and leaktight integrity of its components, (2) the operability and the performance of the active components of the system, and (3) the operability of the system as a whole, and, under conditions as close to design as practical, the performance of the full operational sequence that brings the system into operation for reactor shutdown and for loss-of-coolant accidents, including operation of applicable portions of the protection system and the transfer between normal and emergency power sources [1].”

Discussion

The design provides for testing of operating system components, which are interchanged periodically, for operability and functional performance.

Redundancy and isolation are provided to allow periodic pressure and functional testing of the system as a whole, including the functional sequence that initiates system operation. At any time during reactor operation, each component of the system can be mechanically connected to the preferred power source to demonstrate operability.

3.1.5 REACTOR CONTAINMENT

3.1.5.1 Criterion 50 - Containment Design Basis

"The reactor containment structure, including access openings, penetrations, and the containment heat removal system shall be designed so that the containment structure and its internal compartments can accommodate, without exceeding the design leakage rate and, with sufficient margin, the calculated pressure and temperature conditions resulting from any loss-of-coolant accident. This margin shall reflect consideration of (1) the effects of potential energy sources which have not been included in the determination of the peak conditions, such as energy in steam generators and energy from metal water and other chemical reactions that may result from degraded emergency core cooling functioning, (2) the limited experience and experimental data available for defining accident phenomena and containment responses, and (3) the conservatism of the calculational model and input parameters [1]."

Discussion

The Containment Building is designed to withstand the pressures and temperatures resulting from a spectrum of LOCAs and secondary system ruptures.

Vital Containment Building subcompartments, such as the steam generator compartment, the reactor cavity, and the pressurizer compartment, are designed to withstand, with a safe margin, peak differential pressures resulting from postulated hot-leg, cold-leg, and pressurizer line breaks.

The assumptions used, other details of the containment pressure temperature transient analysis, and the subcompartmental differential pressure analysis are presented in Section 6.2.1. The structural details are described in Section 3.8. See Section 6.2.2 for containment heat removal; Section 3.8 for access openings; and Sections 3.8, 6.2.4, and 8.3 for penetrations.

3.1.5.2 Criterion 51 - Fracture Prevention of Containment Pressure Boundary

"The reactor containment boundary shall be designed with sufficient margin to assure that under operating, maintenance, testing, and postulated accident conditions (1) its ferritic materials behave in a nonbrittle manner and (2) the probability of rapidly propagating fracture is minimized.

"The design shall reflect consideration of service temperatures and other conditions of the containment boundary material during operation, maintenance, testing, and postulated accident conditions, and the uncertainties in determining (1) material properties, (2) residual, steady state, and transient stresses, and (3) size of flaws [1]."

Discussion

The containment liner material meets the requirements of the Proposed Standard Code for Concrete Reactor Vessels and Containment (April 1973) developed by the joint American Concrete Institute (ACI)-ASME Technical Committee on Concrete Pressure Components for Nuclear Service, which is made up of ACI Committee 359 and the ASME B&PV Code, Section III, Division 2, Subgroup on Concrete Components.

Piping penetrating the containment and forming part of the containment pressure boundary meets the requirements of the ASME B&PV Code, Section III, Division 1, particularly paragraph NE 1131 and Subarticle NE 2300.

These requirements ensure conformance to GDC 51.

For additional details, refer to Section 3.8.

NOTE: Inspection of attachment welds during hydrostatic testing, as required by the ASME B&PV Code was not performed on all type MV containment penetrations for Unit 1.

3.1.5.3 Criterion 52 - Capability For Containment Leakage Rate Testing

"The reactor containment and other equipment which may be subjected to containment test conditions shall be designed so that periodic integrated leakage rate testing can be conducted at containment design pressure [1]."

Discussion

The containment is designed and constructed, and the necessary equipment is provided, to permit periodic integrated leakage-rate tests during plant lifetime, in accordance with reduced pressure-test program requirements of 10 CFR 50, Appendix J. For additional details, see Section 6.2.6 and the technical specifications.

3.1.5.4 Criterion 53 - Provisions for Containment Testing and Inspection

"The reactor containment shall be designed to permit (1) appropriate periodic inspection of all important areas, such as penetrations, (2) an appropriate surveillance program, and (3) periodic testing at containment design pressure of the leaktightness of penetrations which have resilient seals and expansion bellows [1]"

Discussion

In accordance with the requirements stated in Section 6.2.6, the design of the containment permits the periodic inspection, surveillance, and testing of the leaktightness of the containment and its penetrations which have resilient seals and expansion bellows.

3.1.5.5 Criterion 54 - Piping Systems Penetrating Containment

"Piping systems penetrating primary reactor containment shall be provided with leak detection, isolation, and containment capabilities having redundancy, reliability, and performance capabilities which reflect the importance to safety of isolating these piping systems. Such piping systems shall be designed with a capability to test periodically the operability of the isolation valves and associated apparatus and to determine if valve leakage is within acceptable limits [1]."

Discussion

Piping systems penetrating the primary reactor containment are provided with containment isolation valves.

Fittings are provided to permit periodic leakage-rate testing of isolation valves to ensure that leakage is within the acceptable limit. (see the technical specifications).

Penetrations that must be closed for containment isolation have redundant valving and associated apparatus as described in Section 6.2.4. Each valve is tested periodically during normal operation or during shutdown conditions to ensure its operability when needed.

3.1.5.6 Criterion 55 - Reactor Coolant Pressure Boundary Penetrating Containment

"Each line that is part of the reactor coolant pressure boundary and that penetrates primary reactor containment shall be provided with containment isolation valves as follows, unless it can be demonstrated that the containment isolation provisions for a specific class of lines, such as instrument lines, are acceptable on some other defined basis:

1. One locked closed isolation valve inside and one locked closed isolation valve outside containment; or

2. One automatic isolation valve inside and one locked closed isolation valve outside containment; or

3. One locked closed isolation valve inside and one automatic isolation valve outside containment. A simple check valve may not be used as the automatic isolation valve outside containment; or

4. One automatic isolation valve inside and one automatic isolation valve outside containment. A simple check valve may not be used as the automatic isolation valve outside containment.

"Isolation valves outside containment shall be located as close to the containment as practical and, upon loss of actuating power, automatic isolation valves shall be designed to take the position that provides greater safety."

"Other appropriate requirements to minimize the probability or consequences of an accidental rupture of these lines or of lines connected to them shall be provided as necessary to assure adequate safety. Determination of the appropriateness of these requirements, such as higher quality in design, fabrication, and testing, additional provisions for inservice inspection, protection against more severe natural phenomena, and additional isolation valves and containment, shall include consideration of the population density, use characteristics, and physical characteristics of the site environs [1]."

Discussion

Each line that is part of the RCPB and penetrates the containment is provided with isolation valves meeting this criterion. For a detailed description of the Containment Isolation System, see Section 6.2.4. Instrument lines are designed in accordance with the requirements of NRC Regulatory Guide 1.11, Instrument Lines Penetrating Primary Reactor Containment.

3.1.5.7 Criterion 56 - Primary Containment Isolation

“Each line that connects directly to the containment atmosphere and penetrates primary reactor containment shall be provided with containment isolation valves as follows, unless it can be demonstrated that the containment isolation provisions for a specific class of lines, such as instrument lines, are acceptable on some other defined basis:

1. One locked closed isolation valve inside and one locked closed isolation valve outside containment; or

2. One automatic isolation valve inside and one locked closed isolation valve outside containment; or

3. One locked closed isolation valve inside and one automatic isolation valve outside containment. A simple check valve may not be used as the automatic isolation valve outside containment; or

4. One automatic isolation valve inside and one automatic isolation valve outside containment. A simple check valve may not be used as the automatic isolation valve outside containment.

“Isolation valves outside containment shall be located as close to the containment as practical and upon loss of actuating power, automatic isolation valves shall be designed to take the position that provides greater safety [1].”

Discussion

Each line that connects directly to the containment atmosphere and penetrates the containment is provided with redundant containment isolation barriers, except where it is demonstrated that the containment isolation provisions for a specific class of lines, such as instrument lines, are acceptable. The failure of one barrier does not result in the loss of isolation capability. Details are provided in Section 6.2.4 and on the corresponding figures listed in Table 6.2.4-1.

The isolation system for each line is designed to fail in a safe mode by designing the air-operated valves and solenoid-operated valves to fail in the direction of greatest safety.

Motor-operated valves, on the other hand, fail in the mode in which they are when failure occurs. Different power sources for each valve in series ensures that isolation is not defeated by a single failure.

3.1.5.8 Criterion 57 - Closed System Isolation Valves

“Each line that penetrates primary reactor containment and is neither part of the reactor coolant pressure boundary nor connected directly to the containment atmosphere shall have at least one containment isolation valve which shall be either automatic, or locked closed, or capable of remote manual operation. This valve shall be outside the containment and located as close to the containment as practical. A simple check valve may not be used as the automatic isolation valve [1].”

Discussion

Each line that penetrates containment and is not connected directly to the containment atmosphere or is not part of the RCPB has at least one isolation valve located outside the Containment Building near the penetration. Details are provided in Section 6.2.4, and on the corresponding figures listed in Table 6.2.4-1.

3.1.6 FUEL AND RADIOACTIVITY CONTROL

3.1.6.1 Criterion 60 - Control of Releases of Radioactive Materials to the Environment

"The nuclear power unit design shall include means to control suitably the release of radioactive materials in gaseous and liquid effluents and to handle radioactive solid wastes produced during normal reactor operation, including anticipated operational occurrences. Sufficient holdup capacity shall be provided for retention of gaseous and liquid effluents containing radioactive materials, particularly where unfavorable site environmental conditions can be expected to impose unusual operational limitations upon the release of such effluents to the environment [1]."

Discussion

Waste handling systems are incorporated in the facility design for processing and/or retention of radioactive wastes for normal operation and anticipated operational occurrences. Controls and monitoring are provided to ensure that releases during normal operation do not exceed a few percent of the limits of 10 CFR Part 20 and yield offsite doses within the numerical guides for design objectives and limiting conditions of operation set forth in 10 CFR Part 50, Appendix I.

Section 9.4 describes the Primary Plant Ventilation System and non-ESF exhaust units which satisfy GDC-60.

Chapter 11 describes the radioactive waste processing systems' design criteria, holdup capacities, and estimated releases of radioactive effluents to the environment. Compliance with 10 CFR Part 50, Appendix I, is described in Appendix 11A.

3.1.6.2 Criterion 61 - Fuel Storage and Handling and Radioactivity Control

"The fuel storage and handling, radioactive waste, and other systems which may contain radioactivity shall be designed (1) to assure adequate safety under normal and postulated accident conditions. These systems shall be designed with a capability to permit appropriate periodic inspection and testing of components important to safety, (2) with suitable shielding for radiation protection, (3) with appropriate containment, confinement, and filtering systems, (4) with a residual heat removal capability having reliability and testability that reflects the importance to safety of decay heat and other residual heat removal, and (5) to prevent significant reduction in fuel storage coolant inventory under accident conditions [1]."

Discussion

The spent fuel pool, Spent Fuel Pool Cooling and Cleanup System, fuel storage and handling system, radioactive waste processing systems, and other systems that contain radioactivity are designed as follows to ensure adequate safety under normal and postulated accident conditions:

1. Components are designed and located so that appropriate periodic inspection and testing can be performed.

2. All areas of the plant are designed with suitable shielding for radiation protection based on anticipated radiation dose rates and occupancy as discussed in Section 12.3.

3. Individual components that contain significant radioactivity are located in confined areas which are adequately ventilated through appropriate filtering systems. Radioactive waste management is discussed in detail in Chapter 11.

4. The Spent Fuel Pool Cooling and Cleanup System provides cooling to remove residual decay heat from the fuel stored in the spent fuel pool and is designed with redundancy and testability to ensure continued heat removal. A purification loop is provided to remove fission product activity. The Spent Fuel Pool Cooling and Cleanup System is described in Section 9.1.

5. The spent fuel pool is designed so that no postulated accident can cause excessive loss-of-coolant inventory.

6. The Primary Plant Ventilation System is designed to filter the exhaust from the fuel storage and handling, radioactive waste and other systems which may contain radioactivity. The non-ESF exhaust units which satisfy GDC-61 are described in Section 9.4.

The piping connected to the fuel pool is designed so that a significant loss of fuel pool water does not occur because of a pipe rupture. Level instrumentation indicates a reduction in fuel pool water level, and redundant sources of fuel pool water are available.

3.1.6.3 Criterion 62 - Prevention of Criticality in Fuel Storage and Handling

“Criticality in the fuel storage and handling system shall be prevented by physical systems or processes, preferably by use of geometrically safe configurations [1].”

Discussion

Criticality in new fuel and spent fuel storage areas is prevented by both physical separation of fuel assemblies and the presence of borated water in the spent fuel storage pool. For the high density Region I racks in Spent Fuel Pool 1 (SFP1) and Spent Fuel Pool 2 (SFP2), the space between storage positions within the rack module and between individual rack modules is blocked to prevent insertion of fuel assemblies. With respect to criticality, there are no administrative restrictions on placement of spent fuel within the high density Region I racks in SFP1 and SFP2. For the high density Region II racks in SFP1 and SFP2, there is no space between storage positions within the rack module and the space between individual rack modules is blocked to prevent insertion of fuel assemblies. Placement of fuel in the high density Region II racks in SFP1 and SFP2 is administratively controlled based on initial enrichment and minimum burnup requirements. Placement of fuel in the spent fuel pool outside of a rack module, such as a gap between the rack module and pool wall or within the oversized inspection cells, is administratively controlled. A discussion of the SFP Region I and Region II oversized inspection cells is contained in the Technical Specification Bases 3.7.17. For high density Region I racks (any storage configuration) and high density Region II racks (1 out of 4 storage

configuration and 2 out of 4 storage configuration), fuel assembly spacing is such that subcriticality is ensured ($k_{eff} \leq 0.95$) even if assemblies are immersed in unborated water. For high density Region II racks (3 out of 4 storage configuration and 4 out of 4 storage configuration) fuel assembly spacing is such that subcriticality is ensured ($k_{eff} \leq 0.95$ taking credit for soluble boron and $k_{eff} < 1.0$ assuming unborated water). Criticality prevention and criticality considerations are discussed in Sections 9.1 and 4.3, respectively. CPNPP complies with 10CFR50.68(b) in lieu of maintaining a system capable of detecting a criticality event as described in 10 CFR 70.24.

The containment refueling cavity of each unit has additional interim storage space for one (1) low density rack. For the low density rack in the refueling cavity, the space between storage positions within the rack module is blocked to prevent insertion of fuel assemblies. There are no administrative restrictions on placement of spent fuel within the low density rack. Fuel assembly spacing is such that subcriticality is ensured ($k_{eff} \leq 0.95$) even if assemblies are immersed in unborated water.

3.1.6.4 Criterion 63 - Monitoring Fuel and Waste Storage

"Appropriate systems shall be provided in fuel storage and radioactive waste systems and associated handling areas (1) to detect conditions that may result in loss of residual heat removal capability and excessive radiation levels and (2) to initiate appropriate safety actions [1]."

Discussion

Monitoring systems are provided to alarm on excessive temperature or low water level in the spent fuel pool so that appropriate safety actions can be initiated by operator action.

Radiation monitors and alarms are also provided to warn personnel of impending excessive levels of radiation or airborne activity. The Area Radiation Monitoring System is described in Section 12.3.4, and the Process Radiation Monitoring System is detailed in Section 11.5.

3.1.6.5 Criterion 64 - Monitoring Radioactivity Releases

"Means shall be provided for monitoring the reactor containment atmosphere, spaces containing components for recirculation of loss-of-coolant accidents fluids, effluent discharge paths, and the plant environs for radioactivity that may be released from normal operations, including anticipated operational occurrences, and from postulated accidents [1]."

Discussion

The Containment Building atmosphere is monitored continuously during normal and transient operations, using particulate, iodine, and gaseous monitors. Under post-accident conditions, samples of the containment atmosphere provide data of existing airborne radioactive concentrations within the Containment Building. Radioactivity levels contained in the facility effluent discharge paths and in the plant environs are continuously monitored during normal and accident conditions by the Process Radiation Monitoring System described in Section 11.5. Provisions for monitoring the plant areas for radioactivity are included in the Area Radiation Monitoring System described in Section 12.3.4. In addition to the installed detectors, periodic surveys are conducted using portable equipment as discussed in Section 12.5.

3.2 CLASSIFICATION OF STRUCTURES, COMPONENTS, AND SYSTEMS

3.2.1 SEISMIC CLASSIFICATION

3.2.1.1 Seismic Category I

The plant structures, Reactor Coolant System, engineered safety features, and safety-related systems and components are identified and classified in accordance with the seismic requirements of General Design Criterion 2 of Appendix A to 10 CFR Part 50, General Design Criteria for Nuclear Power Plants [5]. NRC Regulatory Guide 1.29 [2] designates those structures, systems, and components which must remain functional during the safe shutdown earthquake (SSE) as seismic Category I items.

Specifically, all seismic Category I structures, systems, and components must withstand the effects of the SSE and ensure the following:

1. The integrity of the reactor coolant pressure boundary

2. The capability to shut down the reactor and maintain it in a safe shutdown condition, or

3. The capability to prevent or mitigate the consequences of incidents which can result in potential offsite exposures comparable to the guideline exposures of 10 CFR Part 100

The following structures, systems, and components of the Comanche Peak Nuclear Power Plant (CPNPP), including their foundations and supports, are designated as seismic Category I and are designed to withstand the effects of the SSE.

The pertinent quality assurance requirements of Appendix B to 10 CFR Part 50 are applied to all activities affecting the safety-related functions of these structures, systems, and components as shown in Table 17A-1.

3.2.1.1.1 Seismic Category I Structures

1. Containment Buildings including internal structures

2. Safeguards Buildings including diesel generator room and emergency switchgear room

3.2.1.1.4 Structures and Systems of Mixed Category

None of the plant structures are classified as partially seismic Category I; however, certain structural items within seismic Category I structures are classified as seismic Category II or non-seismic as appropriate. See Table 17A-1, item 36, for typical structural classifications. The boundaries of seismic Category I portions of systems are shown on the piping and instrumentation diagrams in appropriate sections of the FSAR. Seismic category II piping segments located inside a non-seismic building are described in Section 3.2.2.d.

3.2.1.2 Seismic Category II

Those portions of structures, systems, or components whose continued function is not required but whose failure could reduce the functioning of any seismic Category I system or component required to satisfy the requirements of C.1.a through C.1.q of Regulatory Guide 1.29 to an unacceptable safety level or could result in incapacitating injury to occupants of the control room (See Figure 13.5-1) are designated seismic Category II and are designed and constructed so that the SSE would not cause such failure. The pertinent quality assurance requirements of Appendix B to 10CFR50 are applied to all activities affecting the seismic requirements of those systems and components.

Insulation (for in-Containment piping) and/or some non-nuclear-safety portions of the fluid systems listed in 3.2.1.1.2 are designated seismic Category II in Table 17A-1. NNS portions of the HVAC systems listed in 3.2.1.1.2 are also designated seismic Category II in Table 17A-1.

In addition, all, or portions, of the following mechanical systems or components are seismic Category II as described in Appendix 17A and Table 17A-1:

17A SYSTEM

NO.	SYSTEM
6.	Boron Recycle System (BRS)
9.	Combustible Gas Control System
17.	Liquid Waste Processing System (LWPS)
18.	Gaseous Waste Processing System (GWPS)
19.	Solid Waste Management System (SWMS)

17A SYSTEM

NO.	SYSTEM
25.	Fuel Building Ventilation System
28.	Primary Plant Ventilation System

52.	Turbine Plant Cooling Water System
53.	Condensate Polishing System
54.	Condenser Vacuum and Waterbox Priming System
55.	Heater Drains System
56.	Chemical Feed System
58.	Chlorination Systems

3.2.2 SYSTEM QUALITY GROUP CLASSIFICATION

1. General Classification

The system quality group classification applies to fluid systems which are directly depended on to prevent or mitigate the consequences of accidents and malfunctions originating within the reactor coolant pressure boundary or which are relied on to permit reactor shutdown and to maintain the reactor in the safe shutdown condition. These fluid systems are also depended on to contain radioactive material.

Fluid system components important to safety are classified in accordance with the ANSI N18.2-1973, Nuclear Safety Criteria for the Design of Stationary Pressurized Water Reactor Plants [4] classification except as described below. This classification system is compatible with requirements of NRC Regulatory Guide 1.26 [1] and is submitted as an alternate acceptable method of meeting the intent of NRC Regulatory Guide 1.26. Quality standards generally applicable to the safety classifications are given in Table 3.2-1. Clarification of the application of quality standards on a system basis is provided in Appendix 17A.

2. Safety Class Definitions

Fluid system components are classified as Safety Class 1, Safety Class 2, Safety Class 3, and non-nuclear-safety (NNS) in accordance with their importance to nuclear safety. This importance, as established by the assigned safety class, shall be applied in the design, materials, manufacture or fabrication, assembly, erection, construction, and operation. A single system may have components in more than one safety class.

The definitions of safety classes listed apply to fluid pressure boundary components and the reactor Containment. Supports that have a nuclear safety function shall be the same safety class as the components that they support. Selection of loading combinations and design methods for supports is the responsibility of the designer.

a. Safety Class 1

Safety Class 1 applies to components whose failure could cause a Condition III or Condition IV loss of reactor coolant as defined in ANSI N18.2 [4]. Condition III occurrences include incidents any one of which may occur during the lifetime of a particular plant. Condition IV occurrences are faults that are not expected to occur but are postulated because their consequences would include the potential for release of significant amounts of radioactive material. Condition IV faults are the most drastic which must be designed against and thus represent the limiting design case. All components located within the reactor coolant pressure boundary (as defined by 10CFR50.2) are Safety Class 1 as required by 10CFR50.55a with the exception of the 3/4” instrument lines and other 3/4” piping connected to the pressurizer above the normal water level and the pressurizer relief and safety valve discharge line. See Section 5.2.1.1 for additional information.

b. Safety Class 2

Safety Class 2 applies to the reactor containment and to the following components:

1. Components of the reactor coolant pressure boundary not in Safety Class 1

2. Components of safety systems that are necessary to remove heat directly from the reactor or reactor containment, to circulate reactor coolant of any safety system purpose, to control within the reactor containment radioactivity released, or to control hydrogen in the reactor containment. A safety system (in this context) is any system that is necessary to shut down the reactor, cool the core or cool another safety system or the reactor containment (after an accident), or it is any system that contains, controls, or reduces radioactivity released in an accident. Only those portions of a system that are designed primarily to accomplish one of those functions, or the failure of which could prevent accomplishing one of those functions, are included.

c. Safety Class 3

Safety Class 3 is applied to those components not in Safety Class 1 or Safety Class 2:

1. The failure of which would result in release to the environment of radioactive gases normally required to be held for decay, or that are necessary to:

   (a) Provide or support any safety system function

   (b) Control outside the reactor containment airborne radioactivity released in an accident, or

   (c) Remove decay heat from spent fuel

d. Non-Nuclear-Safety

Non-nuclear-safety (NNS) applies to portions of the nuclear power plant not covered by Safety Classes 1, 2, or 3 that can influence safe, normal operation or that may contain radioactive fluids. Design of non-nuclear-safety components shall be to applicable industry codes and standards.

The piping Class G designation is used to identify those non-nuclear safety related (NNS) piping and plumbing lines which are not located in Seismic Category I structures.

The piping Class 5 designation is used to identify those non-nuclear safety (NNS) piping and plumbing lines which are located in Seismic Category I structures. Class 5 piping is designed as seismic Category II or non-seismic. Based on

specific routing, all non-seismic Class 5 lines larger than 2" (larger than 4" for air filled copper tubing) are evaluated for their capability to reduce the functioning of Seismic Category I systems and components as defined in position C.1.a through C.1.q of Regulatory Guide 1.29 to an unacceptable level as the result of an SSE and are seismically supported where required. In some special cases as noted in Table 17A-1, Class 5 lines 2" and smaller are designated as NNS, seismic Category II and seismically supported. As such, all activities affecting the design and construction of Seismic Category II systems are subject to the pertinent quality assurance requirements of Appendix B to 10CFR50.

Sleeve-coupled fittings by LOKRING Technology have been qualified for, and can be used in, non-safety, non-critical B31.1 piping application NPS ¼ to 4 for CS and NPS ¼ to 3 for SS, and including piping whose only design function requirement is to remain in place during and following a Seismic Event, that is mounted Seismic Category II inside Seismic Category I Buildings (Reference FDA-2020-000077-01).

High energy piping segments, which are listed in FSAR Section 3.7B.2.8 as located in the Turbine Building, are designated class 5 piping and classified as seismic Category II. These piping segments are seismically analyzed for break postulation and seismic qualification. Additional analyses are performed to demonstrate that unacceptable interactions of these piping segments with non-Category I structures/components will not occur during a seismic event.

Class 5 lines, which are determined as not reducing the functioning of the systems and components described above to an unacceptable degree, and Class G lines are fabricated and installed in accordance with applicable industry codes and standards.

All, or portions of the systems or components that are Seismic Category II are described in Appendix 17A and Table 17A-1.

3. Radioactive Waste Management System (RWMS)

The RWMS designation is used to identify the boundaries of the radioactive waste management system on applicable CPNPP flow diagrams, as the RWMS does not match the functional system boundaries. The RWMS is considered to begin at the interface valve(s) in each line from other systems provided for collecting wastes that may contain radioactive materials and to terminate at the point of controlled discharge to the environment, at the point of recycle back to storage for reuse in the reactor, or at the point of storage of packaged solid wastes prior to shipment offsite to a licensed burial ground. The RWMS portion of the steam generator blowdown system begins at, but does not include, the outermost containment isolation valve on the blowdown line and terminates at the point of controlled discharge to the environment, at the point of the interface with other liquid waste systems, or at the point of recycle back to the secondary system.

The radioactive waste management system (RWMS) includes portions of the following systems and system which interface with them:

LWPS	Liquid Waste Processing System
GWPS	Gaseous Waste Processing System
SWMS	Solid Waste Management System
CVCS	Chemical and Volume Control System
BRS	Boron Recycle System
SGBS	Steam Generator Blowdown System
SFPCCS	Spent Fuel Pool Cooling and Cleanup System

The piping and components comprising the RWMS are classified seismic category I, II or NONE, and ANS Safety Class 2, 3 or NNS based on their functional requirements as defined in Chapter 11 and as shown in Appendix 17A, Table 17A-1.

3.2.3 PLANT DRAWINGS

Tables 3.2-3 and 3.2-4 correlate FSAR figure numbers to plant drawings. In the electronic FSAR, figures are not located after the tables and can only be accessed/viewed by the use of links. These links are located 1) in the List of Figures portion for each chapter Table of Contents, 2) in FSAR text/tables which reference the specific figure and, 3) in Table 3.2-4 (only for FSAR figures that are also Station drawings (i.e., “E” and “M” series drawings)). FSAR Tables 3.2-3 and 3.2-4 provide a cross reference of station drawing numbers to FSAR figure numbers (only for station drawings that are also FSAR figures.) Links to FSAR figures that have multiple sheets will take you to the first sheet. Once you are linked to the first sheet you can step through the remaining sheets of the figure.

3.2.3.1 Flow Diagrams

The safety classes and their interfaces are depicted in the flow diagrams. Coordinates are provided to all piping and instrument drawings (P&ID’s) for locating equipment and interconnections from figure to figure. For meaning of mechanical symbols and abbreviations, see Figure 3.2-1.

Table 3.2-3 include listing of Unit 1 and Common flow diagrams and of Unit 2 flow diagrams and their respective FSAR Figure Numbers. These drawings provide the details required by Regulatory Guide 1.70, Revision 2, for their respective system sections and for FSAR Sections 3.9 (active pumps and valves), 6.2.4 (containment isolation), Section 6.4 (control room habitability) and for Chapter 7 (instrumentation & controls) which refer to them. The flow diagrams also provide the correlation for ANSI Safety Class 1, 2, and 3 and for NNS fluid system components in Table 17A-1.

Table 3.2-4 provides a numerical listing of FSAR Figure Numbers and their respective flow diagrams.

The flow diagrams contain the following significant information for their respective system:

1. All major components, piping, points where connecting systems and subsystems tie together, and instrumentation associated with the system and subsystems.

2. Safety Classes and their interfaces.

3. Tag numbers for equipment referenced in text and tables throughout the FSAR.

4. The extent of systems located in Containment and the extent of system located Seismic Category I buildings.

5. Other details required by RG 1.70, Revision 2.

The flow diagrams contain the following information which is not significant:

1. Line numbers, manual valve/damper numbers (not referenced in text or tables), and air flow rates on HVAC drawings (except for fan capacity and control room ESF filtration air flows (Figure 9.4-1, Sheets 1 & 2)).

2. Drawing notes not related to system operation or function and not related to RG 1.70, Revision 2 content requirements.

3. Reducer sizes and/or their use attached directly to equipment.

4. Other trivial details which satisfy regulatory requirements and commitments, have no potential safety impact, and was not the basis for the NRC safety review as documented in the SER/SSERs.

3.2.3.2 One Line Diagrams

The safety classification of electrical systems is depicted on plant one line diagrams. Table 3.2-3 include listing of Unit 1 and common one line diagrams and of Unit 2 one line diagrams and their respective FSAR figure numbers.

One line diagrams provide the details required by Regulatory Guide 1.70, Revision 2, for AC and DC power distribution systems.

The one line diagrams contain the following significant information for AC and DC power distribution system.

1. Power supply feeders.

2. Loads supplied from each bus.

3. Interconnections between buses, buses and loads, and buses and supplies.

4. Interconnection between safety-related and non safety-related buses.

5. Power distribution equipment capacities.

6. Safety related equipment identification.

7. Power distribution equipment and buses shared between units.

8. Power distribution circuit protective devices.

9. Other details required by RG 1.70, Revision 2.

The one line diagrams contain the following information which is not significant for the purposes of FSAR figures.

1. Cable numbers.

2. Circuit breaker/fuse numbers

3. Protective device, circuit breaker/fuse/relay, manufacturer type and part numbers.

4. Bus compartment and circuit numbers.

5. Control circuit details showing control and indicating devices, e.g., control switches, elector switches, alarms, status lights, and indicating lights.

6. Schematic and wiring drawing references.

7. Notes not related to power distribution system operation/function and not related to RG 1.70 content requirements.

8. Other trivial details which satisfy regulatory requirements and commitments, have no potential safety impact, and was not the basis for the NRC safety review as documented in the SER/SSERs.

3.2.3.3 Radiation Zone and Shield Thickness Drawings

These drawings depict the radiation protection design features for the entire plant. The information depicted in these drawings provides the details required by Regulatory Guide 1.70, Revision 2 with respect to radiation protection design features. These figures are used to trigger engineering ALARA evaluations of proposed plant changes and thus help to ensure that collective station radiation exposure as well as individual radiation exposure remains ALARA throughout the life of the plant.

Table 3.2-3 includes a listing of Unit 1 and Common radiation zone and shield thickness drawings and of Unit 2 radiation zone and shield thickness drawings and their respective FSAR figure numbers.

Table 3.2-4 provides a numerical listing of FSAR Figure Numbers and their respective radiation zone and shield thickness drawings.

The radiation zone and shield thickness drawings contain the following significant information to describe the CPNPP radiation protection design features.

1. Room and Area Design Radiation Zones

2. Shield Wall Thickness

3. Room and Equipment Layouts

4. Room and Area Access Control Features

5. Area and Process Radiation Monitor Locations

Notes:

1. Pressure vessels which are part of the reactor coolant pressure boundary meet the requirements of 1971 Version of the ASME B&PV Code, with application of all Addenda through and including the Summer 1972 Addenda. Pumps, valves and piping which are part of the reactor coolant pressure boundary meet the requirements of the 1971 Version, with application of all Addenda through and including the Winter 1972 Addenda. Later Code revisions may be used optionally in accordance with requirements of 10 CFR 50.55a.

2. See Reference 3. Code Class 2 and 3 components purchased prior to the effective date of Reference 3 meet the requirements of the Code in effect at the time of purchase (earliest Code specified was the Code in effect on May 1972). Later Code versions, including Code Cases, may be used optionally in accordance with ASME Code implementation requirements.

3. See Reference 6. Later Code versions may be used optionally.

4. See Reference 7, 8, 9. Later Standard versions may be used optionally.

5. See Section 3.8 and Table 17A-1 (for clarification and exceptions).

3.3 WIND AND TORNADO LOADINGS

3.3.1 WIND LOADINGS

3.3.1.1 Design Wind Velocity

Seismic Category I structures are designed for a basic maximum wind velocity of 80 mph at 30 ft above ground based on a 100-year period of recurrence.

The design wind velocity is selected on the basis of U.S. Weather Bureau data for the general area, as indicated in Figure 1(b) of ASCE Paper No. 3269, “Wind Forces on Structures”.

Wind velocity distribution for various height zones above the ground is in accordance with Table 1 of ASCE Paper No. 3269, “Wind Forces on Structures”, and is as follows:

Height Above Ground (ft)	Wind Velocity (mph)
0 to 50	80
50 to 150	95
150 to 400	110
400 to 700	120

A gust factor of 1.1 is applied to the above wind velocities for all seismic Category 1 structures except the yard tanks for which a gust factor of 1.3 is used. The adequacy of a 1.1 gust factor is confirmed by calculations in accordance with Reference 6.

3.3.1.2 Determination of Applied Forces

The dynamic wind pressure q is defined as $q = 0.00256V^2$, where q is in psf and V, the wind velocity (including the gust factor), is in mph. ASCE Paper No. 3269 is used as a guide in determining wind pressure distribution on the structures. For the containment structure and cylindrical tanks, the coefficients are in accordance with Table 4(f) of ASCE paper 3269. For rectangular structures, the shape coefficient is 1.3. The total wind pressure load on the structure is 1.3q; of the 1.3q, 0.8q is applied as positive pressure on the windward walls, and 0.5q is applied as negative pressure on the leeward walls. Concurrently, the end walls receive 0.8q negative pressure, and the roof receives 0.5q uplift.

Any wind shielding effect that one structure can provide to another is neglected.

Wind loads are applied to the structures as static loads. Only dead loads are considered to resist uplift caused by wind loads. Horizontal wind loads are distributed by the walls to roof and floor diaphragms, and they are distributed from these to the foundations by the lateral load-carrying elements of the structural system.

Load combinations that include wind are described in Section 3.8.

3.3.2 TORNADO LOADINGS

All essential systems and components are protected from tornado induced loads in order to maintain the following:

1. The ability to achieve and maintain a safe shutdown in both units.

2. The integrity of the reactor-coolant pressure boundary.

3. The ability to prevent failures that could lead to radioactive releases resulting in offsite exposures greater than 25 percent of the guideline exposures of 10 CFR Part 100.

These systems and components are located within Seismic Category I buildings as listed in Section 3.2.1.1. The arrangement of these structures can be found on the plot plan, Fig. 1.2-1.

Seismic Category I buildings are vented to the atmosphere in the event of a tornado. These buildings are designed to withstand the loadings due to wind, depressurization and repressurization, and tornado generated missiles. These buildings are also designed to provide protection from the tornado and its effects to Seismic Category I systems and components within these structures.

Tornado impingement is not considered coincident with other low probability events such as a Safe Shutdown Earthquake (SSE), loss of coolant accident (LOCA), or a fire. Because of the potential switchyard damage, a trip of the turbine-generators and loss of offsite power are assumed to result from the design basis tornado.

3.3.2.1 Applicable Design Parameters

The design basis tornado has a peripheral tangential velocity of 300 mph. and a translational velocity of 60 mph.

The design basis tornado drops the local atmospheric pressure 3 psi at a constant rate of 1.0 psi/sec. The pressure is then held at -3 psig for 10 seconds at which time repressurization occurs at a rate of 1.0 psi/sec., for a total duration of 16 seconds. The number 10 seconds for the time held at the negative pressure is chosen for analysis purposes to ensure that complete depressurization is considered.

The spectrum and pertinent characteristics of tornado generated missiles are described in Section 3.5 on Table 3.5-8. Missile loads are considered to act simultaneously with wind and pressure loads.

3.3.2.2 Tornado Protection Design Features

Venting from the building interior compartments to the exterior is provided by blow-out door F-4EX, tornado pressure relief dampers, and tornado pressure relief blowout panels.

1. Blow-out door F-4EX

   The Fuel Building is primarily vented by an opening covered by blow-out door F-4EX. This door is designed to blowout when subjected to tornado induced loading.

2. Tornado Pressure Relief Dampers in Exterior Walls

All exterior tornado dampers are specified to remain closed during winds with speeds up to 119 mph. Tornado dampers in exterior walls are specified to open in either direction when the differential pressure across the damper reaches 0.25 psi in either direction. Concrete missile shields, as shown on Figure 3.3-1, protect the dampers and the building interior from tornado generated missiles.

3. Tornado Pressure Relief Blowout Panels

Airtight blowout panels are used in the venting of the Auxiliary Building, the Control Room and the Safeguards Building. All blowout panels are specified to remain airtight during winds with speeds up to 119 mph. Blowout panels are specified to open when the differential pressure across the panel reaches 0.25 psi. Where a missile can impact a blowout panel, a Seismic Category I building is protected by reinforced concrete missile resisting walls and roof so arranged as to stop a missile as shown in Figure 3.3-2 and Figure 3.3-3. Where a missile is stopped by a concrete barrier and could then enter by gravity into a Category I building protective grating is provided as shown in Figure 3.3-3.

The Diesel Generator Building is primarily vented through the Diesel Generator air intakes.

Venting between interior compartments that are separate fire areas is provided by fire rated architectural door openings, tornado pressure relief dampers (in series with fire dampers), and fire rated HVAC air transfer grilles.

1. Fire Rated Architectural Door Openings

Door E-3AX is specified to blowout of the E&C building into the turbine building. The door is designed to blowout when subjected to tornado induced loading.

Several standard hollow metal doors are held open with fusible link arm-holders designed to close the door during a fire. Wire-mesh doors are also provided for radiation protection (access control) as required. Where other considerations, such as HVAC integrity, require that a hollow metal door be closed, and venting is still required the door is modified in such a way as to allow it to release during a tornado. These doors are also restrained during release to prevent destruction of the door. Fire rated doors are also provided in the same doorway and are also held open with fusible link arm-holders designed to close the door during a fire.

2. Tornado Pressure Relief Dampers in Interior Fire Walls

These dampers are normally closed, where required to provide a ventilation or other environmental boundary, and are specified to open in either direction when the differential pressure across the damper reaches 3" wg. except for selected dampers located in the Safeguards Buildings which have been modified by permanently opening a portion of the modules of each damper to provide an airflow path through areas served by the Electrical Area Ventilation System to the Main Steam and Feedwater Area Ventilation System air inlet duct in the Mechanical Equipment Room (1(2)-104).

The tornado dampers located in the UPS HVAC chase are also normally closed and open in either direction when the differential pressure reaches 7.5" wg.

3. Fire Rated Air Transfer Grilles

Several fire-rated HVAC air transfer grilles are considered for tornado venting. These vents are not attached to ductwork which would potentially block the vent. These vents are normally open.

Venting between interior compartments that are not separate fire areas is provided by access gratings, excess area in wall penetrations, tornado pressure relief dampers and architectural door openings.

1. Tornado Pressure Relief Dampers in Interior Walls

These dampers operate in the same manner as the interior dampers in the fire-rated openings.

2. Architectural Door Openings

Several wire-mesh doors are provided for tornado venting.

Several hollow-metal doors are provided with air transfer louvers. In cases where doors are required by other considerations to be in closed positions, some doors are designed to blow open when subjected to tornado induced loading.

Since the tornado venting characteristics of the buildings are dependent on the positions of architectural doors, these positions must be considered. Applicable plant design documents show all doors that have a required open position for purposes of tornado venting. Seismic Category I structures are designed to withstand the impact loads from the spectrum of tornado generated missiles as shown in Table 3.5-8. Structures are of sufficient thickness to prevent perforation or the generation of secondary missiles by tornado generated missiles to which they can be exposed.

Non-Seismic Category I structures or structural components whose failure under tornado loading could possibly impair the function of Seismic Category I structures, equipment, systems or components are designed to withstand the effects of the tornado loading to the extent that the functional requirements of Seismic Category I structures, equipment, systems and components are not impaired.

3.3.2.3 Method of Analysis

The dynamic wind pressure, q, is calculated from the following equation:

$$q = 0.00256\ V^2$$

where:

q = wind pressure [psf]

v = wind velocity [mph]

The tornado wind velocity is not assumed to vary with height above the ground. The tornado wind pressure is applied as a static load. The pressure distribution and shape coefficients for tornado loadings are the same as the coefficients used for wind, as described in Subsection 3.3.1.2. For all Seismic Category I structures a 360 mph wind velocity is applied uniformly. A gust factor of 1.0 shall be used.

For Seismic Category I buildings other than the Containment the effects of venting are considered in determining the maximum pressure differential across building wall, floor and roof systems. Calculations of differential pressure loads are made utilizing an improved version of the COMPARE - Mod 1 computer code. The subcompartments are represented as volumes that are connected by pressure-dependent variable area junctions or vents. The volume thermodynamics are based on a homogeneous gas, assumed to undergo a quasi-static process. Flow between volumes is based on a one dimensional solution of the momentum equation that includes an accounting for the effects of inertia. Air is assumed to be an ideal gas. The relative humidity is assumed to be zero for conservatism in terms of pressure. For analysis purposes the turbine building is considered to exist at atmospheric environmental conditions. This is justified by the nature of the building design. No flow is considered available through HVAC ductwork due to the potential for damage to it.

Volumes in the flow model represent separate rooms, groups of rooms, or sections of rooms so that the maximum attainable differential pressure across any structure inside a volume is analytically shown to be 0.25 psi.

Tornado missile impact velocities and barrier requirements are presented in Section 3.5. The procedures used for transforming tornado-generated missile loadings, which are considered impactive dynamic loads, into effective loads are described in Section 3.5. Load combinations that include tornados are described on Section 3.8. A load factor of 1.0 is used for tornado loads in the load combination equations. The load factor is justified by the low probability of occurrence at a specific point, by the short duration of associated loading, and by the conservative nature of the maximum tornado wind velocity selected. Non-Seismic Category I equipment that is not in a Seismic category I building and hence can possibly become a tornado generated missile is evaluated as a potential missile. Because the damage potential of such a missile is not greater than the effect of the spectrum of tornado-generated missiles listed in Table 3.5-8 the equipment is not protected from tornado loads.

3.3.2.4 Design Evaluation

The various combinations of tornado effects which the structures will withstand are as follows:

$W_t = W_w$

$W_t = W_p$

$W_t = W_m$

$W_t = W_w + 0.5\ W_p$

$W_t = W_w + W_m$

$W_t = W_w + 0.5\ W_p + W_m$

where:

W_t = total tornado load

W_w = tornado wind load

W_p = tornado differential pressure load

W_m = equivalent tornado missile load

The local design of the exterior walls and roofs of each Seismic Category I structure provides each element with the capability to withstand the most adverse of the six load combinations in each direction. All interior structural components in Seismic Category I structures are verified to withstand the pressure load only. This is justified by the low air velocities induced by the relatively large flow areas inside the rooms. These interior structures include non-load bearing partitions such as fire-walls, windows, and accoustic ceilings which could potentially become missiles if damaged. The same loading combinations are considered to act on all doors that are not specified as a pressure relief door or not required to be open and which could potentially become a missile if damaged. The structural capabilities of hollow metal doors are verified by the ASTM test method.

Since the interior of the building depressurizes, the electrical and I&C cabinets are subject to pressure loadings in the same manner as the buildings. Available vents are measured and pressure loadings are determined in the same manners as the buildings. The pressure loadings are transformed into member stresses and displacements by a stress analysis. All cabinets containing equipment required to achieve and maintain a safe shutdown during and after a tornado, and to operate tornado protection devices are verified to maintain the structural integrity and the operability of the equipment when subjected to tornado pressure loads.

The Safe Shutdown Impoundment (SSI) Dam has outer surfaces or shells of limestone rock with a minimum thickness of 10 feet. This minimum thickness occurs only at the crest of the dam; the rock thickness increases rapidly below the crest to a maximum of more than 100 ft. (each surface) at the base of the embankment. The penetration of any tornado missile from the spectrum presented in Table 3.5-8 into such a surface is far less than the minimum thickness of the limestone. However, even if total penetration of the longest missile of the spectrum considered can somehow occur, and even if the direction of penetration is parallel to and located at the SSI water level, a limestone rock and filter thickness that exceeds the total missile length by 56 percent is present on either dam surface. The longest missile is considered to be a 35-ft. (10.68-m) long utility pole.

Squaw Creek Dam is not a Category I structure and the effect of a tornado missile is not pertinent.

TABLE 3.3-1
HAS BEEN DELETED.

3.4 WATER LEVEL (FLOOD) DESIGN

3.4.1 FLOOD PROTECTION

Seismic Category I equipment, systems, and components in the Service Water Intake Structure are located above the probable maximum flood (PMF) level and do not require protection from flood. The PMF is considered in the design of the submerged pump shafts.

The following seismic Category I systems and components are located below the PMF level of 789.7 ft:

Safeguards Building:

1. Containment Spray System - containment spray pumps

2. Residual Heat Removal System - RHR pumps

3. Safety Injection System - SIS pumps

4. Vents and Drains System - floor drain sumps and pumps

Grade elevation for the structure in which these seismic Category I system components are located is 810.0 ft. No doors or entries to these structures are located below 810.0 ft. There is, then, no possibility of flooding these components from the PMF condition.

Water stops are used in all construction joints below grade even though the ground water elevation as outlined in Section 2.5.4.6 is no higher than 775.0 ft. Sump pumps are provided to handle the minute amounts of water which could leak into the structures.

Since there is no possibility of flooding any of these seismic Category I components as a result of PMF or ground flooding, no specific flood protection of the above equipment is required.

Electrical and Control Building:

1. Safety Chilled Water System - Chillers and pumps

2. UPS and Distribution Room Air Conditioning System - Air Conditioning Units

Grade elevation for the structure in which these seismic Category I system components are located is 810.0 feet. Doors to this structure are located above PMF level with the exception of three doors into the Turbine Building at Elevation 778 feet (see Figures 1.2-31, 22, and 27).

Flooding of the Turbine Building due to PMF is prevented because the Circulating Water and its interconnecting system are closed systems (See Section 10.4). In addition, if Squaw Creek Reservoir elevation rises above 778 feet, the operators will verify that any Circulating Water System equipment which is to be opened for maintenance will be isolated from Squaw Creek Reservoir by valves and/or stop-gates. Due to the access opening in the operate deck of the circulating water discharge structure, the stop gates isolate the CW Tunnels for lake levels below 778 feet only. Any open CW system at elevation below the PMF level of 789.7 feet must be closed or isolated in order to isolate the lake levels above 778 from the open pathway that could

lead to flooding of the Turbine Building and lower level of the Electrical & Control Building on Elevation 778.

Therefore, it is not necessary to bring the reactor to a cold shutdown for flood conditions.

3.4.2 ANALYSIS PROCEDURES

Grade elevation of safety-related structures, except the Service Water Intake Structure, is 810.0 ft. The PMF level is 789.7 ft. Thus no direct static or dynamic effects of the design basis flood conditions are considered for these structures. Initially, the static hydrostatic pressure that results from the ground water elevation of 775.0 ft. was considered in the design of structures located below this elevation. The design-basis groundwater elevations were later changed to 793 ft-0 in for the Service Water Intake Structure (SWIS) and 810 ft-0 in for other safety-related structures. All safety-related structures have been designed for these groundwater levels. Hydrostatic pressure p is determined from the following equation:

$$p = \gamma h$$

where

γ = the unit weight of water

h = the depth below the groundwater elevation

The Service Water Intake Structure is protected from the effects of wind-wave activity on the Squaw Creek Reservoir by the Safe Shutdown Impoundment Dam, but it is subject to wind-wave activity on the Safe Shutdown Impoundment. A 40-mph wind is assumed coincidental with the PMF (789.7 ft). The wind-wave activity at the Service Water Intake is negligible; therefore, there are no significant dynamic forces to be considered. The maximum water level used in design, as a hydrostatic load, takes into consideration the maximum runup elevation caused by a 40-mph wind coincident with the PMF. An 80-mph sustained wind has been superimposed on a normal water level of 775 ft which results in a lower combined setup and runup elevation than the still water elevation that occurs during the PMF. Therefore, this is not a critical design condition with regard to maximum water level at the Service Water Intake Structure.

The Service Water Intake Structure is not subject to flood currents; therefore, dynamic water force as a result of flood currents is not a design load.

3.4.3 FLOODING FROM TANK RUPTURE

Table 3.4-1 lists all the non-seismic Category I liquid storage tanks larger than 1500 gallons located in the Containment, Safeguards and Auxiliary buildings. The effects of flooding on shutdown capability of the plant were analyzed assuming that the release of tank contents is instantaneous and the sump pumps will not be operational. In all cases, tank rupture results in local flooding only, with no effect on plant safety or the plant safe shutdown capability. Tanks less than or equal to 1500 gallons are bounded by the room design described in Section 9.3.3.3.

3.5 MISSILE PROTECTION

3.5.1 MISSILE SELECTION AND DESCRIPTION

The basic approach to ensure missile protection of systems and components both inside and outside of Containment involves:

1. Examination of systems in order to identify and classify potential missiles

2. Postulation of the generation of potential missiles and the provision of protection against them

3. Insurance of the design adequacy of equipment against the generation of missiles.

3.5.1.1 Internally Generated Missiles (Outside Containment)

The principal design bases are that missiles generated outside of Containment but internal to the plantsite do not cause damage to a system or component, (which is provided for either continued safe operation or shutdown during operating conditions, operational transients, and postulated accident conditions) which are associated with the effects of missile formation. The seismic category and quality group classifications for these systems are identified in Section 3.2.

Equipment outside Containment (see Section 3.5.2) has been evaluated for potential missile sources. The information in this section concerning potential missile sources and systems which require protection from internally generated missiles outside Containment is provided as a result of that evaluation.

The specific systems which require protection from missiles are a function of the missile source analysis and are listed in Table 3.5-1. Systems outside Containment which are required for safe shutdown of the reactor are protected regardless of the missile source.

3.5.1.1.1 Missile Selection

In order to conservatively establish the protection and redundancy requirements for safety-related equipment, missile generation is postulated to occur from high energy systems and rotating equipment. Only one source of a primary missiles is postulated for each event.

3.5.1.1.2 Missile Protection

To prevent a total loss of safety-related system integrity due to internally generated missiles, general design provides two redundant trains for each safety-related system. These trains are separated by missile barriers so that one missile, if it is generated in a system, cannot damage a redundant train of any system.

In addition, systems and components which are identified as potential missile sources are, wherever possible, arranged and oriented so that the tangent structure or component is capable of withstanding the impact, and the design criteria are not violated.

In order to determine the effects of a postulated missile, safety-related equipment is considered and protection is only provided for essential safety-related equipment (as defined in 3.6B.1.2.1) on a case by case basis.

In general, safety-related pumps, tanks, heat exchangers, and other large components are placed in separate compartments surrounded by missile barriers. Piping is run in common pipe chases, and valves are located in common valve rooms. For safety-related equipment, the pipe chases and valve rooms for different trains in general are isolated from each other so that a missile in one pipe chase or valve room cannot affect any equipment in the other chase or room.

Information on postulated turbine missiles is provided in Section 3.5.1.3.

3.5.1.1.3 Design Adequacy of Equipment

Equipment within Westinghouse scope has been reviewed for design adequacy against missile generation.

1. Valves

   Valves in high-pressure systems have been reviewed. As a result of this review, it is concluded that there are no credible sources of missiles associated with valves because there is no single failure associated with any potential valve parts that can result in the generation of a missile. Therefore, there are no missiles associated with valves within Westinghouse scope outside the Containment.

2. Pumps

   Pumps located (within Westinghouse scope) outside the Containment have been evaluated for missiles associated with overspeed failure. The maximum no-load speed of these pumps is equivalent to the operating speed of their motors. Consequently, no pipe break or single failure in the suction line can increase pump speed over that of the no-load condition. Furthermore, there are no pipe break plus single failure combinations which can result in a significant increase in pump suction or discharge head. Therefore, no overspeed is expected, and missiles associated with pumps within Westinghouse scope outside Containment are not credible.

3. Generator Flywheel

   The fabrication specifications of the motor generator set flywheels control the material, and are in accordance with ASTM A 533, 7D, Grade B, Class I, with inspections in accordance with MIL-I-45208A; flame cutting and machining operations are governed to prevent flaws in the material. Nondestructive testing for nil ductility (ASTM E208) and Charpy V-notch (ASTM A 593), as well as ultrasonic testing (ASTM A 578 and A 579) and magnetic particle testing (ASME B&PV Code, Section III, Paragraph NB 2545) are performed on each flywheel material lot. In addition to these requirements, stress calculations are performed in conformance with guidelines of the ASME B&PV Code, Section III, Appendix A, to show that the combined primary stresses caused by centrifugal forces and the shaft interference fit do not exceed one-third of the yield strength at normal operating speeds (1800 rpm) and do not exceed two-thirds of the yield strength at 25 percent overspeed. However, no overspeed is expected because the

flywheel weighs approximately 1300 lb and has dimensions of 35.26 in. in diameter by 4.76 in. in width. The flywheel mounted on the generator shaft, which is directly coupled to the motor shaft, is driven by a 200 hp, 1800 rpm induction motor. The torque developed by the motor is insufficient for overspeed. Therefore, there are no credible missiles from the motor generator sets.

3.5.1.2 Internally Generated Missiles (Inside Containment)

The principal design bases are that missiles generated within the Containment do not cause loss of function of any structure, system or component whose failure could lead to offsite radiological consequences or which is required for safe plant shutdown to a cold condition assuming an additional single failure. The seismic category and quality group classifications for nuclear steam supply systems and components are in Section 3.2.

Equipment (outside of and within Westinghouse scope) inside Containment (see Section 3.5.2) has been evaluated for potential missile sources. As a result of this review, the following information concerning potential missile sources and systems which require protection from internally generated missiles inside Containment is provided:

3.5.1.2.1 Missile Selection

1. Equipment Within Westinghouse Scope

The possibility of a catastrophic failure of the reactor vessel, steam generators, pressurizer, reactor coolant pump casings, and piping that can lead to generation of missiles is not considered credible. Massive and rapid failure of these components is not credible because of the material characteristics; inspection; quality control during fabrication, erection, and operation; conservative design; and prudent operation, as applied to the particular component. The reactor coolant pump flywheel is not considered a source of missiles for the reasons discussed in Section 5.4.1. Nuts and bolts are of negligible concern because of their small amount of stored elastic energy.

NSSS components which are considered to have a potential for Missile Generation inside the reactor containment are as follows:

a. control rod drive mechanism (CRDM) housing plug, drive shaft, and the drive shaft and drive mechanism latched together

b. Certain valves

c. Temperatures and pressure sensor assemblies

d. Pressurizer heaters

Gross failure of a CRDM housing sufficient to allow a control rod to be rapidly ejected from the core is not considered credible for the following reasons:

a. Full-length CRDMs are shop tested at 3107 psig (Unit 1) or 3450 psig and 4105 psig, respectively (Unit 2).

b. Unit 1

The mechanism housings are inspected and leak tested as they are installed on the reactor vessel to the head adapters.

Unit 2

The mechanism housings are individually hydrotested to 3107 psig as they are installed on the reactor vessel to the head adapters, and checked during the hydrotest of the completed RCS.

c. Stress levels in the mechanism are not affected by system transients at power, or by thermal movement of the coolant loops.

d. The mechanism housings are made of Type F304LN (Unit 1) or Type 304 (Unit 2) stainless steel. This material exhibits excellent notch toughness at all temperatures encountered.

However, it is postulated that the top plug on the CRDM becomes loose and it is forced upward by the water jet (Unit 2). The following sequence of events is assumed: the drive shaft and control rod cluster are forced out of the core by the differential pressure of 2500 psi across the drive shaft. The drive shaft and control rod cluster, latched together, are assumed to be fully inserted when the accident starts. After approximately 12 ft of travel, the rod cluster control spider hits the underside of the upper support plate. Upon impact, the flexure arms in the coupling, which join the drive shaft and control cluster, fracture and completely free the drive shaft from the control rod cluster. The control cluster is completely stopped by the upper support plate; however, the drive shaft continues to be accelerated upward to hit the missile shield provided. A description of the missile shield is provided in Section 3.5.1.2.4.

a. Valves

Valve stems are not considered credible sources of missiles.

All the isolation valves installed in the RCS have stems with a back seat. This effectively eliminates the possibility of ejecting valve stems even if the stem threads fail. Stems are threaded into a yoke and are locked in place with a locking bar. The actuator assembly around the yoke consists of other structural components as the frame which surrounds the spring adjustment and spring. Failure of the stem below the threaded region would be blocked by these components which are directly above the stem. The stem cannot be ejected sideways due to the fact it would be guided by the bonnet, packing and/or the trim depending on the location of the failure. In addition, the valves have a backseat or stop which will provide another mechanism against the stem being ejected. The backseat or stop would prevent the lower portion of the stem from exiting the valve [12].

Additional interference is encountered with air- and motor-operated valves.

Valves with a nominal diameter larger than 2 in. have been designed against bonnet body connection failure and subsequent bonnet ejection by the following means:

1. By using the design practice of the ASME B&PV Code, Section VIII, which limits the allowable stress of bolting material to less than 20 percent of its yield strength

2. By using the design practice of the ASME B&PV Code, Section VIII for flange design

3. By controlling the load during the bonnet body connection stud tightening process

The pressure-containing parts are designed in accordance with Class 1, 2, or 3 requirements established by the ASME B&PV Code, Section III.

The proper stud-torquing procedures and the use of torque wrench, with indication of the applied torque, restrict the stress of the studs to the allowable limits established in the ASME B&PV Code, Section III. This stress level is far below the material yield. The complete valves are hydrotested in accordance with the ASME B&PV Code, Section III. The stainless steel bodies and bonnets are volumeterically tested and surface-tested to verify soundness.

Valves with a nominal diameter of 2 in. or smaller are forged and have a screwed bonnet with a canopy seal. The canopy seal is the pressure boundary, while the bonnet threads are designed to withstand the hydrostatic and force. The pressure-containing parts are designed in conformance with the criteria established by the ASME B&PV Code, Section III.

While valve missiles are not generally postulated (the reasons are as previously mentioned), the valves in the region where the pressurizer extends above the operating deck are exceptions. Valves in this region are the pressurizer safety valves, the motor-operated isolation valves in the relief line, the air-operated relief valves, and the air-operated spray valves. Although failure of these valves is also considered not credible, failure of the valve bonnet body bolts is nevertheless postulated, and provisions are made to assure integrity of the Containment liner from the resultant bonnet missile.

To the extent practical, all valves are also oriented so that a missile will strike a barrier.

All BOP valves in high energy systems located inside the Containment Building are evaluated.

b. Thermowells

The only credible source of jet-propelled missiles from the reactor coolant piping and piping systems connected to the RCS is that represented by the temperature and pressure sensor assemblies. The resistance temperature sensor assemblies

can be of two types: with well and without well. Two rupture locations have been postulated: around the weld (or thread) between the temperature element assembly and the boss for the without well element, and the weld (or thread) between the well and boss for the with well element.

A temperature sensor is installed on the reactor coolant pumps close to the radial bearing assembly. A hole is drilled in the gasket and sealed on the internal end of the steel plate. In evaluating missile potential, it is assumed that this plate can break and the pipe plug on the external end of the hole can become a missile.

In addition, it is assumed that the welding between the instrumentation well and the pressurizer wall can fail and that the well and sensor assembly can become a jet-propelled missile.

c. Pressurizer Heaters

Finally, it is assumed that the pressurizer heaters can become loose and become jet-propelled missiles.

2. Equipment Outside of Westinghouse Scope

In order to conservatively establish the protection and redundancy requirements for safety-related equipment, credible missile generation from the following sources are evaluated:

a. Valves in high energy systems;

b. Temperature and Sensor Assemblies in high energy systems;

c. Vessels and Compressed Gas Cylinders in high energy systems; and

d. Dynamic Equipment.

3.5.1.2.2 Missile Description

The CRDM Missiles are summarized in Table 3.5-2.

The missile characteristics of the valve bonnets in the region where the pressurizer extends above the operating deck are given in Table 3.5-3 while the missile characteristics of the piping temperature sensor assemblies are given in Table 3.5-4. A 10-degree expansion, half angle water jet is assumed. The missile characteristics of the piping pressure element assemblies are less severe than those of Table 3.5-4.

The missile characteristics of the reactor coolant pump temperature sensor, the instrumentation well of the pressurizer, and the pressurizer heaters are given in Table 3.5-5. A 10-degree expansion, half-angle water jet is assumed.

The missile characteristics of equipment that are in Westinghouse scope are given in Table 3.5-6.

3.5.1.2.3 Missile Protection

Internal missiles which can be generated from pressure-containing components that are part of the RCS or main steam and feedwater systems are considered in the design of the Containment. The entire RCS and parts of the main steam and feedwater system are surrounded by the secondary shield wall and their components, arranged so that a missile generated from one component does not damage any other component whose failure can lead to an offsite radiation dose in excess of that prescribed in 10 CFR Part 100. Equipment that is not in the Westinghouse scope is either surrounded by concrete barriers, provided with redundant counterparts or designed to adequately resist missile generation or external penetration.

Missile barriers and missile resistant structures are of sufficient thickness and strength to prevent emission of secondary missiles when struck by a primary missile.

3.5.1.2.4 The Control Rod Drive Shaft Missile Shield

Unit 1 Missile Shield

Damage to equipment inside the Containment or to the Containment itself caused by missiles generated by the failure of a CRDM housing (as described in Section 3.5.1.2.1) is prevented by an integral steel missile shield. This missile shield is circular with an approximate outside diameter of 134 inches, constructed of an array of W6 x 16 carbon steel beams welded to the top of a 1.5 inch thick carbon steel plate and built to seismic Category I requirements. The missile shield is part of the CRDM cooling plenum assembly and is approximately 5 feet above the top of the CRDM pressure housings. The missile shield's array of W6 x 16 carbon steel beams are bolted to the plenum's carbon steel support column assembilies. These support columns are bolted to plenum's upper ring girder and lower ring girder. The plenum is mounted to the head assembly and is positioned above the seismic support platform and the CRDM and DRPI cable connections. The plenum assembly is attached to the head lift rig via the lift rig extension sections. The plenum missile shield assembly remains installed of the reactor vessel head assembly during refueling.

Unit 2 Missile Shield

Damage to equipment inside the Containment or to the Containment itself caused by missiles generated by the failure of a CRDM housing (as described in Section 3.5.1.2.1) is prevented by a roll-away steel missile shield. (See Figure 3.5-1) This missile shield is approximately 16 ft. square and constructed of 2-inch-thick carbon steel plate and built to seismic Category I requirements (no function after the LOCA is required). The shield which is located over the refueling cavity and is approximately 2 feet above the top of the CRDM housings is mounted on the manipulator rails for ease of removal during refueling. (See Figure 3.5-2.)

The CRDM cooling fans, along with cable trays containing cables which are connected to the CRDMs, are mounted on the missile shield. Neither the fans nor the cables are nuclear-safety-related and therefore do no have to be protected from damage resulting from missile impact on the shield.

During refueling, the cables are removed from the cable trays and the shield is rolled to the far end of the manipulator rail where it is stored throughout refueling. The fans are not removed

from the shield during refueling. When refueling is completed, the shield is positioned over the reactor and the cables are reinstalled in the cable trays.

3.5.1.2.5 Secondary Missiles

As stated in Section 3.5.1 the basic approach to ensure missile protection of safety systems and equipment inside the Containment Building has been the assurance of the design adequacy of equipment against the generation of missiles rather than to try to contain the missile. The precautions taken to prevent missile generation are as described in Section 3.5. In spite of the design precautions, the generation of potential missiles is postulated and the provision for protection against them is described in Section 3.5. It has not been postulated that secondary missiles are generated by impingement of these missiles.

3.5.1.3 Turbine Missiles

3.5.1.3.1 Turbine Placement and Orientation

Turbine missiles have been evaluated not to be a credible threat for the CPNPP design basis.

3.5.1.3.2 Turbine Overspeed Protection

For a detailed description of the operational mechanism for the overspeed protection components of the turbine, refer to Section 10.2.2. The components reliability analysis has been based on the following assumptions:

1. Failure rates for the turbine valves and controls derived primarily from actual operating experience and calculated with a statistical confidence level of 95 percent

2. The turbine valves are tested per the Preventative Maintenance Program. The overspeed protection system is automatically tested periodically during each shift and is verified operational per the Preventative Maintenance Program. The turbine trip block is tested per the Preventative Maintenance Program.

3. An average of one true load rejection per year

4. Consideration of the turbine extraction of common mode failure possibilities in addition to random failures

Thus, the overspeed failure probability has been estimated to be very small (1.37×10^{-5} per turbine-year for a four flow turbine generator) and per the Preventative Maintenance Program turbine valve test interval [15], and subsequently a high degree of component reliability exists.

3.5.1.3.3 Turbine Valve Testing

Periodic testing of the stop and control valves is necessary to insure reliability and continuity of service; therefore, valve testing for all nuclear units is recommended with a manual test or with the aid of an automatic turbine tester (ATT) per the Preventative Maintenance Program.

For high reliability of the electrohydraulic control (EHC), one primary AC power source for valve testing is provided from safeguard bus; two separate DC sources for control circuits are provided from one +24 VDC system with common neutral. For more details of inservice inspection, refer to Section 10.2.3.6.

3.5.1.3.4 Turbine Characteristics

The turbine is a multicasing, tandem compound, four flow, reaction type, 1800-rpm unit with 46-in. last stage blades. For more detailed characteristics, refer to Section 10.2.2.

For major components, rotor materials and their properties, steam environment, and other properties related to the turbine disk integrity, refer to Section 10.2.3.

Turbine operational and transient characteristics are analytically described in Section 10.2.1 (Design Bases).

3.5.1.4 Missiles Generated by Natural Phenomena

The seismic Category I structures are designed for the effects of tornado-generated missiles. The missile characteristics are shown in Table 3.5-8.

Missiles, generated by floods, are not a design consideration as the PMF is lower than grade elevation. The Service Water Intake Structure is designed for tornado-generated missiles, among other loads. This provides adequate protection for any low velocity waterborne object.

The safety-related systems/components and non-safety related 1E components not contained within reinforced concrete buildings or structures are:

1. Service Water traveling screens

2. Diesel fuel oil storage tanks

3. Instruments located in the turbine building

4. Feedwater control and bypass valve appurtenances

5. Auxiliary Feedwater Pump (AFWPT) Exhaust Stack

The safety related Service Water traveling screens are intended for long term protection of the Service Water System from accumulation of debris (ie. CCW Heat Exchanger tube plates) and for short term protection against floating debris, small enough to pass through the trash racks positioned ahead of the screens, but large enough to potentially damage the Service Water Pumps.

In the event that the exposed parts of both screens, are struck by missiles, the only mechanical consequence is that the screens could lose their ability to rotate. The screens are positioned in channels which prevent the screen from collapsing following a postulated missile strike on the non-protected portion.

Local essential lighting for the Service Water System is located within the reinforced concrete service water structure but adjacent to a door not designed to resist damage from a tornado missile. The essential lighting fixtures, fixture primary supports, lamps and bulbs are classified non-nuclear safety grade. Essential lighting systems are discussed in Section 9.5.3.2.

The diesel fuel oil storage tanks and associated piping are located underground adjacent to the diesel building and are protected by a 1 foot 9 inch thick reinforced concrete slab at grade level. Manholes for the tanks are protected by steel plate covers with a minimum thickness of 1 3/4 inches.

Instruments that actuate anticipatory reactor trip on turbine trip are located in the turbine building as shown on Figure 7.1-3, sheet 16. They are included in the design as good engineering practice. The instruments are procured as Class 1E but are not Nuclear Safety Related and are not protected from tornado missiles because their function is anticipatory, not essential. The anticipatory reactor trip on turbine trip is discussed in Section 7.2.1.1.2 item 6.

The electrical appurtances on the Feedwater control and bypass valves, and the cables and junction boxes serving them, are non-safety related, but designated as Class 1E. Credit is taken for these valves in the analysis of the Feedwater Line Breaks and Main Steam Line Breaks inside Containment as non-safety related backup to the Nuclear Safety Related Feedwater Isolation Valves. This equipment is not protected against tornado missiles because these pipe rupture events are not postulated to occur simultaneous with a tornado.

The Turbine Driven AFW Pump steam supply and exhaust stack has been evaluated for tornado-generated missile strikes resulting from missiles as described in Table 3.5-8 originating from all potential directions. Missile strikes on the steam exhaust stack and the flash tank vent pipes were analyzed using the explicit time-history finite element method. The analysis assumed concurrent missile strikes on the exhaust stack and on the two flash tank vents. The analysis determined that the exhaust stack and the two flash tank vents would not crimp shut in a manner that would prevent the turbine driven pump from performing its safety function nor would it adversely impact any plant SSCs required for safe shutdown.

All other safety related equipment is located within reinforced concrete structures.

The SSW discharge piping which extends from the discharge structure is classified as NNS (see Figure 9.2-1) and is not protected from tornado missiles. An analysis of tornado missile impacts on the exposed piping shows that the flow area reduction is acceptable and SSW would be able to perform its safety functions during and after a tornado.

The Refueling Water Storage Tank vents described in Section 6.3.3.7 and the Condensate Storage tank vents described in Section 9.2.6 are classified as non-Nuclear Safety related and, in accordance with ANSI N18.2a, are designed to break away if struck by a tornado missile. The exterior walls and roofs of all building housing safety-related equipment are of reinforced concrete and are designed to protect safety-related equipment against damage from the effects, including tornado missile effects, of the design basis tornado of Region I.

The buildings and structures housing safety-related equipment are shown on FSAR Plot Plan Figure 1.2-1.

Barriers are located at all exterior wall and roof openings of buildings or structures housing safety related equipment to prevent tornado missiles from damaging the contained safety related equipment.

The types of barriers used are:

1. Door openings - All safety related equipment is protected against damage from tornado missiles by missile resistant steel doors or steel plates completely covering the opening.

2. Ventilation Pressure Barriers - Where openings are provided for blow-out panels, tornado dampers, or air intake louvers, all safety related equipment is protected against damage from tornado missiles either by exterior missile resistant reinforced concrete barriers completely surrounding the opening or by missile resistant concrete barriers inside the building. In cases where a postulated missile is stopped by an interior concrete barrier and could then fall into the structure, a grating is provided.

3. Hatch Openings - All safety related equipment is protected against damage from tornado missiles by missile resistant steel plates completely covering the roof openings. Manhole covers on top of all outdoor seismic Category I tanks are steel plate with a thickness of no less than 1 3/4 inches.

   Tornado missiles are postulated to impact normal to the plant structure with maximum mass and velocity as defined in Table 3.5-8 of the FSAR.

3.5.1.5 Missiles Generated by Events Near the Site

As described in Section 2.2, potential missiles generated by events near the site will not endanger any safety-related facilities.

3.5.1.6 Aircraft Hazards

As discussed in Section 2.2, aircraft missiles are not considered a design basis.

3.5.2 SYSTEMS TO BE PROTECTED

All plant structures, systems, and components whose failure can lead to offsite radiological consequences or which are required to shut down the reactor and maintain it in a safe condition, assuming an additional single failure, are listed in Section 3.2. In general, reinforce concrete floors and internal compartment walls are used as barriers for protection of all essential components and systems against postulated missiles. For arrangement of floors and internal walls, see Figures 3.8-1 through 3.8-4. For general arrangement, see Figures 1.2-1 through 1.2-46.

3.5.3 BARRIER DESIGN PROCEDURES

Only one missile is postulated at a time and is assumed to strike the barrier end-on.

The missiles have two effects on structures, walls, or any other barrier: local effects and overall response. The local effects include penetration, perforation, and spalling or scabbing. The overall response includes the flexural and shear effects.

Reinforced concrete external roofs and walls of seismic Category I structures form barriers against tornado-generated missiles. Buried underground, safety-related duct runs and piping are also protected.

3.5.3.1 Local Effects

The estimate of missile penetration (D) in concrete barriers is based on the Modified Petry Formula [1]. Sufficient thickness of concrete is provided to prevent perforation, and when required, to prevent backface spalling or scabbing. To prevent perforation, a concrete thickness of at least twice the penetration thickness determined for an infinitely thick slab is provided. The thickness (T) of the concrete barrier, to prevent backface spalling or secondary missiles which are injurious to safety-related equipment, is determined by the following equation [1]:

$$T = 2.4D$$

D is the maximum penetration in an infinitely thick slab. A minimum concrete barrier thickness of 30 inches for exterior walls and 21 inches for roofs is provided for protection from tornado-generated missiles. See Section 3.8.4.1.7 for a discussion of the properties of the concrete and typical reinforcement details.

Determination of penetration by missiles into steel plates is in accordance with the Stanford Research Institute Formula [2], or the Ballistic Research Lab Formula [10].

3.5.3.2 Overall Barrier Response

The overall response of structural barriers to missile impact depends upon the available ductility. This ductility is a function of the controlling nature of the structural behavior. Thus, for concrete beams, walls, and slabs, where flexure controls design, the permissible ductility ratio is taken as 0.05/(p - p'), p being the ratio of tension reinforcement and p', the ratio of compression reinforcement. However, the ductility ratio does not exceed 10.0 for beams, walls, and slabs. For beam, walls, and slabs where shear may control design, the ductility ratio is 1.0 when shear is carried by concrete alone, and 1.3 when shear is carried by concrete and stirrups or bent bars. Flexural strength is determined based on ultimate strength theory with the limitations on ductility as follows:

1. For beam-column members where the compressive load does not exceed either 0.1 f'C Ag or one-third of that which would produce balanced conditions, whichever is smaller, the allowable ductility ratio is 10.

2. For beam-column members where the design is controlled by compression, the allowable ductility is 1.3.

3. For members which are between these two values, ductility shall be taken as decreasing linearly from 10 to 1.3.

For steel barriers, the ductility ratio does not exceed 10.0 for flexure, compression or shear. For steel columns proportioned to preclude elastic buckling, (l/r equal to or less than 20) the limiting ductility ratio is 1.3. For steel columns not proportioned to preclude elastic buckling (l/r greater than 20), the limiting ductility ratio is 1.0, where l is the effective length of the member and r is the

least radius of gyration. For steel tension members, the limiting ductility ratio is taken as 0.5 Eu/Ey, where Eu is the ultimate strain and Ey is the yield strain.

The design load, caused by the missile, is based on the absorption of the kinetic energy of the missile by the target at its maximum Deflection [4]. It is limited by the yielding, buckling, crushing, or local failure of the missile.

Missile		Mass (kg)	Dimensions (m)	Velocity (m/sec)	Kinetic Energy (kg-m)
A.	Wood plank	52	.092 x .289 x 3.66	83	18,300
B.	6-in. Schedule 40 pipe	130	.168D x 4.58	52	17,900
C	1-in. steel rod	4	.0254D x .915	51	530
D.	Utility pole	510	.343D x 10.68	55	78,600
E.	12-in. Schedule 40 pipe	340	.32D x 4.58	47	38,300
F.	Automobile	1810	5 x 2 x 1.3	59	321,000

Note:

Vertical velocities of 70 percent of the postulated horizontal velocities are used except for Missile C, which is used to test barrier openings. Missile C is assumed at the same speed in all directions. Kinetic energy for vertical impact is reduced according to missile velocity.

3.6N PROTECTION AGAINST DYNAMIC EFFECTS ASSOCIATED WITH THE POSTULATED RUPTURE OF PIPING

3.6N HAS BEEN DELETED

3.6B PROTECTION AGAINST DYNAMIC EFFECTS ASSOCIATED WITH THE POSTULATED RUPTURE OF PIPING

This section describes the design bases and protective measures used to ensure that all essential structures, systems and components required for a safe shutdown and to maintain the reactor in a cold shutdown condition are adequately protected from the dynamic effects associated with postulated pipe ruptures located inside and outside of the containment. The criteria for protection against pipe ruptures conforms to the requirements of Appendix A of 10 CFR 50 General Design Criterion 1, 2, 4 and 14. The pipe rupture protection criteria also conforms to the guidelines of NRC Regulatory Guide 1.46 [1], Standard Review Plans 3.6.1 and 3.6.2 [2], and Branch Technical Positions APCSB 3-1 [3] and MEB 3-1 [2].

3.6B.1 POSTULATED PIPING FAILURES IN FLUID SYSTEMS

This section sets forth the design bases, description, and safety evaluation for protection and determination of the dynamic effects associated with the postulated rupture of piping in fluid systems both inside and outside containment.

3.6B.1.1 Design Basis

The following design bases are utilized in determining the consequences of pipe failures on essential systems or components important to plant safety or shutdown (see Section 3.6B.1.2) which are located in the vicinity of high or moderate energy piping:

1. Piping systems, valves and components required to achieve a safe shutdown will be protected.

2. Required redundancy will be maintained in the protection system (IEEE Standard 279), Class 1E electric systems (IEEE Standard 308), ESF equipment, cable penetrations and their interconnecting cables.

3. HVAC equipment required for safe shutdown will be protected. Portions of Primary Plant Ventilation and associated chilled water are credited after 72 hours to mitigate the long term effects of HELBs outside containment. This is sufficient time to effect required repairs.

4. Instrumentation required for post accident monitoring will be protected as described in Section 7.5.1.3.1.3.

5. Containment leaktightness will be maintained.

6. LOCA breaks will not propagate to steam and/or feed water line breaks and vice versa.

7. A non-LOCA break will not be allowed to propagate into a LOCA.

8. LOCA break propagation to the unaffected Reactor Coolant System loops will be prevented.

9. LOCA propagation in the affected loop is permitted, but is limited as discussed in Section 3.6B.1.2.2.

10. In-core instrumentation lines will be protected.

The criteria for determining the location of pipe breaks is given in section 3.6B.2.1. A discussion of the effects of pipe failure on each system and typical piping runs with the location of failure points shown on drawings is given in subsection 3.6B.2.5 for high energy systems.

A list of high energy lines that are considered for pipe rupture analysis is included as Table 3.6B-1.

All large bore High Energy Lines in safety related structures are Seismic Category I and II. Small bore High Energy Lines in safety related structures are Seismic Category I or II except for the main steam line drip pot drain lines in the Safeguards Building, Main Steam and Feedwater Penetration Area. See Table 3.6B-1 for applicable line numbers.

3.6B.1.2 Description

Essential systems are defined as those systems that are needed to shut down the reactor and mitigate the consequences of the pipe break for a given postulated piping break.

3.6B.1.2.1 Protection Criteria

Depending upon the type and location of the postulated pipe break, certain safety equipment may not be classified as essential for the particular event. Some safety equipment will be essential for almost all cases. This category includes service water to the ultimate heat sink and the pressurizer level instrumentation. The containment integrity and leak tightness will be maintained for any LOCA break. The effects of a postulated piping failure, including environmental conditions resulting from the escape of contained fluids, will not preclude habitability of the control room or access to surrounding areas important to the safe control of reactor operations needed to cope with the consequences of the piping failure. Accordingly, protection from the effects of pipe rupture will be provided for only that safety-related equipment considered as essential on a case-by-case basis.

The systems or portions of systems and equipment for which protection against postulated pipe failures is required are identified below. However, in general, protection from pipe failure need not be provided if any of the following conditions exists:

1. The piping is physically separated (or isolated) from structures, systems, or components important to safety by protective barriers, or is restrained from whipping.

2. Following a single break, the unrestrained pipe movement of either end of the ruptured pipe about a plastic hinge formed at the location determined by calculation cannot impact any structure, system, or component important to safety.

3. The internal energy level associated with the whipping pipe can be demonstrated to be insufficient to impair the safety function of any structure, system, or component to an unacceptable level.

The following systems or portions of these systems are required to mitigate the consequences of a postulated pipe failure:

1. Auxiliary Feedwater System
2. Chemical and Volume Control System
3. Feedwater System
4. Main Steam System
5. Reactor Coolant System
6. Residual Heat Removal System
7. Safety Injection System
8. Safety Chilled Water System
9. Hydrogen and Nitrogen System
10. Containment Spray System
11. Diesel Generator System
12. Component Cooling Water System
13. Service Water System
14. HVAC Systems required for the operation of other systems
15. Containment Isolation System
16. Control Room Ventilation System
17. Class 1E electrical systems, ac and dc (including switchgear, cables, batteries and distribution systems)

The instrumentation required to mitigate the consequences of a postulated pipe break and/or for accident monitoring is discussed in Sections 7.4, 7.5 and 7.6.12.

The results of the environmental analysis, which discuss the effects of pressure, temperature, humidity, and flooding on safety related equipment, are provided in Sections 3.11 and 3.6B.2.5. The only high-energy lines located near the Control Room are the main steam and feedwater lines which are located outside the Control Room adjacent to the north and south walls. Accordingly, protection is provided as described in Section 3.6B.2.5 so that habitability of the Control Room is not jeopardized by postulated pipe failures.

3.6B.1.2.2 LOCA Break Propagation Criteria

A loss of reactor coolant accident is assumed to occur for a branch line break down to the restraint of the second normally open automatic isolation valve (Case II in Figure 3.6B-10) on outgoing lines and down to and including the second check valve (Case III in Figure 3.6B-10) on incoming lines normally with flow. A pipe break beyond the restraint or second check valve will not result in an uncontrolled loss of reactor coolant if either of the two valves in the line closes.

Accordingly, both of the automatic isolation valves are suitably protected and restrained as close to the valves as possible so that a pipe break beyond the restraint will not jeopardize the integrity and operability of the valves. Further, periodic testing capability of the valves to perform their intended function is essential. This criterion takes credit for only one of the two valves performing its intended function. For normally closed isolation or incoming check valves (Cases I and IV in Figure 3.6B-10) a loss of reactor coolant accident is assumed to occur for pipe breaks on the reactor side of the valve.

Branch lines connected to the Reactor Coolant System are defined as “large” for the purpose of these criteria if they have an inside diameter greater than 4 inches. Rupture of these lines results in a rapid blowdown from the Reactor Coolant System and protection is basically provided by the accumulators and the low head safety injection pumps (residual heat removal pumps).

Branch lines connected to the Reactor Coolant System are defined as “small” if they have an inside diameter equal to or less than 4 inches. This size is such that Emergency Core Cooling System analyses using realistic assumptions show that no clad damage is expected for a break area of up to 12.5 square inches.

In order to assure the design function of essential systems in the event of a LOCA, break propagation within the affected loop shall be limited as follows:

1. Reactor Coolant Loop Piping

   Propagation of damage resulting from rupture of the main reactor coolant loop is permitted to occur but must not exceed the design basis for the containment, environmental qualification of equipment and Emergency Core Cooling System performance.

   The application of Leak-Before-Break technology to CPNPP Unit 1 and 2, discussed in Section 3.6B.2.1.1, has shown that the dynamic effects of main reactor coolant loop rupture, such as loop hydraulic forces, reactor internals reaction loads and primary equipment support loads, can be excluded from the design basis, as allowed by General Design Criterion 4 (Section 3.1.1.4).

2. Large Branch Lines

   In the event of a rupture of a large branch line resulting in a LOCA, propagation of the break in the affected loop must not exceed 20 percent of the flow area of the line which initially ruptured.

3. Small Branch Lines

In the event of a rupture of a small branch line resulting in a LOCA:

a. Break propagation must be limited to the affected leg of the affected loop.

b. Propagation of the break in the affected leg must be limited to a total break area of 12.5 square inches. However, no propagation is permitted when the initiating small break is the high head safety injection line.

c. Propagation of the break to a high head safety injection line connected to the affected leg is prevented if the line break results in a loss of core cooling capability due to a spilling injection line.

3.6B.1.2.3 Environmental Analysis to Determine HELB Temperature Transients for Purposes of Equipment Qualification (Outside Containment)

1. Design Bases

Environmental analyses are performed to model the thermal effects of HELBs on safety related areas and equipment outside containment that are needed for safe shutdown of the plant. This information is used to determine that the plant can be safely shutdown following a high energy line break.

The environmental effects of HELBs are analyzed for those systems where breaks or cracks are required to be postulated that have the potential of releasing steam or flashing water. These systems include Main Steam, Feedwater, Chemical and Volume Control, Steam Generator Blowdown and Auxiliary Steam.

2. Analytical Techniques

The COMPARE/MOD1A computer code is used to model the effects of HELBs. COMPARE is a thermal-hydraulic modeling code that is used for subcompartment transient analyses. It models the physical plant arrangement as a series of volumes and junctions. The volumes are made up of rooms, parts of rooms or groups of rooms that are combined together to form one volume. The junctions are naturally occurring flow paths based on the geometry of the plant.

The COMPARE code has the ability to calculate the transient conditions in up to 100 volumes that are connected by up to 200 junctions. Each volume is assumed to contain a homogeneous mixture of air, steam and water. The volumes may contain heat conduction elements. Mass and energy addition (blowdown) may also be added to a volume.

Mass and energy accounting is performed on each volume for each discrete time step. This then describes the thermodynamic conditions, which are assumed to be constant, from which the new junction flows are calculated. Several options are available to calculate the junction flows. These are a homogeneous equilibrium gas mixture, a two-phase Moody critical flow model or an inertial flow model based on the solution of the

one-dimensional momentum equation with critical flow based on one of the first two methods listed. The third is the option used for the C.P.S.E.S.

Doors whose angular positions are a function of pressure, spring forces, gravity forces or inertia forces can be represented to model the vent flow area.

Heat sinks can be modeled into the volumes and the associated parameters can include density, specific heat, initial conditions, boundary conditions, changes in materials and changes in heat transfer coefficients.

3. Plant Models

Because of the locations of the postulated high energy line breaks outside containment, several detailed computer models of the plant are developed. These models are used to calculate the effects of breaks occurring in the main steam and feedwater penetration areas, the safeguards building, the auxiliary building and the electrical and controls building. The models are based on the physical arrangement of the as-built plant and include door positions, tornado dampers, blowout panels, blowout doors, equipment removal gratings, ventilation transfer grills and physically isolated areas. The door positions are in accordance with those specified by the Tornado Analysis.

For each of the plant models many different kinds of input information is calculated. Some of the calculated input parameters include the room volumes corrected by subtracting the volume occupied by large piping and major equipment, the specific surface areas of the walls, floor and ceiling for input as a heat sink and junction inertial values (L/A) specific to each of the flow paths of the as-built plant. Also the exact free area of the tornado dampers, blowout panels and blowout doors are used, along with the geometry of each to accurately model the swing of each as a function of time and differential pressure.

Sensitivity analyses are performed by changing several input parameters, one at a time, to determine the adequacy of the parameters used in the analysis.

A survey is made of all the compartments in the plant that contain HELBs and the governing worst case break for each of the compartments is determined. Using the plant models mentioned above, each of the individual breaks that is the governing case for its compartment is then analyzed to determine the plant environment.

Using the results of the above analyses, a study is then performed to determine equipment affected by the environment. The affected equipment is then evaluated, on a case by case basis, to determine the equipment required for safe shutdown.

4. The governing results for each room and piece of equipment in terms of temperature, pressures and relative humidities are used as input to Section 3.11.

This input is then used to equate whether the existing demonstrated (maximum) qualification parameters envelope the short duration HELB parameters for temperature, pressure and relative humidity. Where the HELB parameters are not enveloped by the existing environmental qualification parameters, an Engineering Analysis is performed. This analysis is performed in order to justify continued operability during (where required)

and after the HELB event, with no appreciable degradation in performance or qualified life of the affected safety or non-safety related electrical equipment.

5. Break Exclusion Areas

For the main steam piping, the break exclusion region extends to the moment restraint downstream of the main steam isolation valve. The restraint is located next to the main steam isolation valve (at the outside wall of the Safeguards Building). It is designed to withstand the loadings resulting from a postulated piping failure beyond the break exclusion region so that neither isolation valve operability nor the leaktight integrity of the containment will be impaired.

For the main feedwater piping, break exclusion region extends to the moment restraint upstream of the main feedwater control valve. The moment restraint is designed to withstand the loadings resulting from a postulated piping failure beyond the break exclusion region. In addition to the main steam and main feedwater piping, about 10 ft of main feedwater bypass piping connected to each of the four main feedwater piping is also designated as a break exclusion region (Unit 2 only).

The piping in the break exclusion regions is designed to meet the requirements of the ASME B & PV Code, Section III, Subarticle NE-1120 and the additional design requirements specified in Branch Technical Position MEB 3-1.

The combination low stress and fatigue, in combination with augmented inservice inspection, precludes the possibility of pipe breaks or cracks in the break exclusion regions. However, for the purpose of determining environmental qualification requirements for safety related equipment in the break exclusion region, a non-mechanistic one square foot crack is postulated.

Method of Analysis

1. Introduction

A subcompartment multinode pressurization analysis has been performed using the COMPARE - MOD 1A computer code which is described in Reference [27]. The analysis results provide information on environmental effects of cracks in the 32-inch main steam pipe or the 18-inch main feedwater pipe within their respective compartments in the Safeguards Building. In addition, flooding due to the above has also been evaluated.

In accordance with the criteria stated in Section 3.6B.2.1.2, no specific pipe breaks are postulated in the above lines within the Safeguards Building. However, to provide an additional level of assurance of safety-related equipment operability in these compartments, the building structure and safety related equipment were reviewed for the environmental conditions (pressure, temperature and flooding), that would result from a non-mechanistic crack, equal in area to one square foot of either a main steam line or feedwater line. The mass and energy release data assumes that the non-mechanistic crack is independent of the location of the MSIV; that is, the open MSIV on the line with the postulated crack is not required to close on steam line isolation to limit the mass and energy release. This conservative assumption is the only failure of equipment outside the main steam and feedwater compartments or qualified equipment inside the compartment

for this scenario. Thus, no single failure or loss of offsite power need be assumed. In addition, the scenario need not assume that the event causes a loss of offsite power since FSAR Section 8.2.2 provides the results of analyses which show that loss of offsite power due to a reactor trip/turbine trip from 100% power is not probable. It is assumed that jets are not generated and hence jet loads are not considered.

Peak compartment temperatures were found to occur following the onset of a postulated MSLB using blowdown data that includes superheated steam effects. This analysis is detailed in FSAR Section 3.6B.2.5.2 and Tables 3.6B-4A (Unit 1), 3.6B-4B (Unit 2) and 3.6B-5.

The method used for the pressurization analysis of the structural compartments in the Safeguards Building is similar to the method used in the subcompartment analyses of the containment structure (Section 6.2.1.2) except that: (1) no asymmetric loading has been analyzed and (2) the type and size of break is limited to a one square foot non-mechanistic crack.

Analyses have been performed for each unit.

2. Compartment Nodalization

The affected compartments in the Safeguards Building containing the high energy lines are represented in a nodalization scheme by a series of volume nodes. The compartment boundaries are shown in Figure 3.6B-207. The line cracks were postulated in room numbers 108A through 108H for main steam and in room numbers 100A through 100H for feedwater, respectively.

In addition, flooding level calculations were based on a feedwater line crack in room numbers 100A, 100B, 100E and 100F.

The choice of nodal subdivisions was governed by the actual physical subdivision of the structure (natural boundaries) which form flow restrictions.

3. Vent Openings and Flow Obstructions

In determining the maximum levels of pressure and temperature resulting from the postulated cracks, a conservative approach was taken in that no credit was taken for utilizing the various building structures and equipment as heat sinks that would contribute to lowering the calculated pressure and temperature.

Venting between the affected compartments is obtained by the following:

a. Floor openings in main steam compartments nearest the Containment Building (room numbers 108A, 108B, 108C, 108D).

b. The seven-feet by three-feet openings in walls of all the compartments, each opening being located seven-feet above the compartment floor.

c. Pipe sleeve openings.

The total area considered for venting from the main steam and feedwater compartments consists of the following:

a. Pipe sleeve openings through the west wall of the Safeguards Building from room numbers 108E, 108F, 108G, 108H, 100E, 100F, 100G and 100H.

b. Pipe sleeve openings for the safety and relief valve vent stack piping through the roof of room numbers 108A, 108B, 108C and 108D.

Seals for these pipe sleeves are provided for weather protection. They have little strength and will "blow out" at a very low differential pressure. For the purpose of analysis, the seals are discounted. The vent openings are modeled as flow paths (or junctions) between each compartment.

For the purpose of calculating the temperature and pressure inside the main steam and feedwater compartments, flow obstruction is assumed to occur as a result of the failure of HVAC ducts passing between the various main steam and feedwater compartments from the compartments to outside areas. These ducts are assumed to fail in such a way as to block any flow that normally would pass through them. Also, the equipment hatches located on the roof of the main steam isolation valve compartments and the seals provided in the gaps between the Safeguards and Containment Buildings are assumed to remain in place.

Structural Design Margins

The main steam line and feedwater line compartments in the Safeguards Building are designed to withstand the environmental effects (pressure, temperature, humidity and flooding) of a non-mechanistic crack in a main steam or feedwater line with a flow area of one square foot. These effects are not combined with seismic effects and are not factored (the load factor is taken as unity). In addition it is assumed that jets are not generated and hence jet loads are not considered.

Mass and Energy Release Rates

1. Main Steam Line Break

The mass and energy release rates were obtained from Westinghouse. Data for the limiting case (1 ft^2 steam line split at 90% including power uncertainty) is shown in Table 3.6B-4A (Unit 1) and Table 3.6B-4B (Unit 2).

2. Main Feedwater Line Break

The worst case crack in the main feedwater line occurs downstream of the check valve. For Unit 1, the mass and energy release rates were developed using RELAP5/MOD 3 [36].

For Unit 2, the mass and energy release rates were developed based on methodology consistent with ANSI/ANS 58.2, Appendix E (see Table 3.6B-6).

Design Data

The main steam and feedwater isolation valve compartments are located on the two top floors of the Safeguard Building which is situated between the Containment Building and the Electrical and Control Building. Figure 3.6B-207 provides plan and elevation drawings of the Safeguard Building.

The main steam and feedwater piping in this area consists of straight piping runs approximately 40-feet long, extending from the containment penetrations, through the compartments to moment limiting restraints mounted in the Safeguards Building wall through which these lines exit to the outside. The compartments contain the main steam line isolation valves, main steam safety valves, main steam power-operated relief valves, main steam isolation bypass valves, steam supply valves to the auxiliary feedwater turbine pump, feedwater isolation valves, feedwater isolation bypass valves and auxiliary feedwater containment isolation valves. The piping arrangement is shown in Figure 3.6B-208.

Also in the subcompartments are various instruments and controls, cables and branch piping lines for the main steam drain and secondary sampling system.

Environmental Effects

The ability to safely shutdown the plant will not be affected by the release of steam and water in the main steam and feedwater compartments. Plant design allows for loss of one main steam and feedwater loop and associated equipment without jeopardizing the safe shutdown of the plant. The following discussion addresses design, operation and consequences of failure of equipment located inside the main steam and feedwater compartments (See Table 3.6B-5 for detail of equipment qualification for MSLB).

1. Main Steam Isolation Valves (MSIVs) and Bypass Valves

   The MSIVs and their electrical supplies are designed to operate at the maximum environmental conditions resulting from the postulated main steam or feedwater pipe crack. These valves except for the valve in the compartment where the crack is located, are required to close following a main steam line or feedwater line crack in order to limit the blowdown through the crack to one steam generator. The signal to close is derived from steam line pressure transducers located on the main steam line inside the compartment. These instruments are qualified for the above environment.

   The MSIV bypass valves are not required for safe-shutdown. These valves are locked closed manual valves and no failure could cause them to open.

2. Power-Operated Main Steam Relief Valves (PORV's)

   These valves are air-to-open, fail closed. The pressure transducers which provide the signal to open these valves must not fail in a mode which could cause the PORV on an intact steam generator to inadvertently open. The PORVs for the steam generator associated with the crack may fail in either the open or closed position without increasing the severity of the event beyond the present analysis or decreasing the ability to mitigate the event and safely shutdown the unit. The PORVs and pressure transducers have a

demonstrated operability beyond that required for their safety function (See Table 3.6B-5).

3. Auxiliary Feedwater Turbine Steam Supply Valves

The failure mode of the valve in the compartment with the crack due to the accident environment does not prevent safe shutdown of the unit. The valve in the compartments without the crack have a demonstrated operability beyond that required for its safety function.

4. Auxiliary Feedwater Containment Isolation Valves

These valves are motor operated, fail-as-is and are normally open and de-energized. Consequently, the accident environment cannot cause these valves to close. It is not postulated that there is a requirement to close the valve supplying auxiliary feedwater to the faulted steam generator because the auxiliary feedwater pump and flow control valves which are isolated from the break environment would be available to perform this function. The valves have a demonstrated operability beyond that required for their safety function.

5. Auxiliary Feedwater Flow Indicators

These instruments indicate flow in the control room for accident monitoring, but have no control function. Although other indication could perform this function (eg. steam generator level) these instruments must not fail in a manner that could lead operators to defeat or fail to accomplish a required safety function. They have a demonstrated operability beyond that required for the safe plant shutdown.

Flooding Evaluation

The worst flooding will occur as a result of a feedwater line break in any one of the feedwater piping compartments 100A through 100D. The water spills over an opening 7' high and 3' wide into compartments 100E through 100H. The maximum flood height in the break compartment is 9.56’. The maximum flood level in the spill over compartment is 8.06’. The structural integrity of the building will not be impaired as a result of these flood levels concurrent with the maximum pressure developed.

Chronology of Events

During the following events, the maximum temperature occurs inside the compartments during the main steam line crack and the maximum pressure occurs during the feedwater line crack.

1. Main Steam Line Crack

Maximum temperature inside the compartments containing essential equipment is reached within 155 seconds into the event. The time sequence of events for the MSLB with superheat is described in Table 3.6B-4A (Unit 1) and Table 3.6B-4B (Unit 2).

2. Feedwater Line Crack

   Low water level in the affected steam generator causes reactor trip and auxiliary feedwater pump start. Feedwater pumps will continue to deliver feedwater to the crack for approximately two minutes when low water level in the condenser hot wells causes the condensate pumps to trip. Low suction pressure will trip the main feed pumps and consequently pumped flow to the crack will be terminated. At that time steam from all steam generators and from the auxiliary feedwater being added to the faulted loop steam generator will be emitted from the crack. Main steam isolation occurs on low steam pressure or on operator action. Operator action terminates auxiliary feedwater addition to the faulted steam generator. The steam leakage phase of the feedwater line crack accident will increase the environmental temperature to a level which is less than that reached during the main steam line crack accident. The maximum pressure occurs during the water leakage phase of the feedwater line crack accident.

3.6B.1.3 Safety Evaluation

The results of the pipe whip and jet impingement analyses, which verify that the consequences of failures of high energy lines do not affect the ability to safely shut down the plant, are provided in the corresponding FSAR sections for the systems listed in Section 3.6B.1.2.1. Incorporated in the analyses are the results of the failure modes and effects analysis, which are described in the safety evaluation section for each system.

Specific design features utilized for the protection of essential systems are identified in Section 3.6B.2.5. Protection for essential structures and components to ensure that their minimum required function can be accomplished following a postulated pipe rupture is provided by one or more of the following methods:

1. Separation and remote location of piping from essential structures and components. Separation is achieved by physical plant arrangements that provided sufficient distances between essential structures, components and piping such that the effects of postulated pipe ruptures cannot impair the structural integrity or operability of the essential structure or component.

2. Barriers, shields and enclosures. Barriers, shields or enclosures are provided for piping or, alternatively, protection of components within structures or compartments is provided. These elements are designed to withstand and contain the effects of the postulated pipe ruptures.

3. Pipe whip restraints. Where physical separation, shields or enclosures are not feasible, protection of essential systems and components is attained by the use of pipe whip restraints and barriers. Alternatively, essential systems and components may be designed to withstand the effects of the postulated pipe rupture.

The design criteria for the restraints are given in Section 3.6B.2.3.

No protection or restraints are provided when it is determined that the piping failure will not cause unacceptable damage to essential systems.

Each longitudinal or circumferential break in high-energy fluid system piping is considered separately as a single postulated initial event occurring during normal plant conditions.

In analyzing the effects of postulated piping failures, the following assumptions are considered with regard to the operability of systems and components:

1. Offsite power is assumed to be unavailable if a trip of the turbine-generator system or reactor protection system is a direct consequence of the postulated piping failure.

2. A single active failure is assumed in systems used to mitigate consequences of the postulated piping failure and to shut down the reactor, except as noted in (3) below. The single active component failure is assumed to occur in addition to the postulated piping failure and any direct consequences of the piping failure, such as unit trip and loss of offsite power.

3. Where the postulated piping failure is assumed to occur in one of two or more redundant trains of a dual-purpose moderate-energy essential system, (i.e., one required to operate during normal plant conditions as well as to shut down the reactor and mitigate the consequences of the piping failure), single failures in the other train or trains of that system are not assumed provided the following conditions are met:

   a. The system is designed to seismic Category I Standards.

   b. The system is powered from both offsite and onsite sources.

   c. The system is constructed, operated, and inspected to quality assurance, testing, and in-service inspection standards appropriate for nuclear safety systems.

4. All available systems, including those actuated by operator actions, are employed to mitigate the consequences of a postulated piping failure. In judging the availability of systems, account is taken of the postulated failure and its direct consequences such as unit trip and loss of offsite power, and of the assumed single active failure and its direct consequences.

5. Operator action credited to mitigate the consequences of the postulated pipe failure is analyzed for each specific event. In general, no operator action is considered to mitigate the consequences of a postulated pipe failure for 30 minutes.

   However, if detection and termination of blowdown can be accomplished in the control room, then an operator action of 10 minutes is credited.

6. A whipping pipe has insufficient energy to cause loss of structural (pressure retaining) integrity in target piping systems of equal or larger nominal pipe size and wall thickness and has sufficient energy to cause through-wall leakage cracks in target piping systems of equal or larger nominal pipe size but with less wall thickness. Any whipping pipe has sufficient energy to cause loss of function of active components such as valves, pumps and motors.

7. Unless it is determined by appropriate calculations or tests, a jet emanating from either a circumferential or a longitudinal break of a high energy system has sufficient energy to

cause loss of structural integrity in piping systems of smaller diameter, through wall leakage cracks in larger pipes with lesser wall thickness, and loss of function in active components such as valves, pumps and motors. Check valves that have equal or larger nominal pipe size and wall thickness than the pipe containing the break shall remain operable.

8. Credit is taken, where possible for automatic valves which fail in the safe position.

9. Essential components which are qualified or can be demonstrated to operate in an adverse environment due to a pipe failure are not protected.

The protective measures utilized, as described in this section, will not prevent the access required to conduct the inservice examinations specified in the ASME Boiler and Pressure Vessel Code, Section XI, Division 1, “Rules for Inspection and Testing of Components in Light-Water Cooled Plants.”

All essential systems, components, piping, component enclosures, protective structural barriers and structures supporting pipe whip restraints are designed to seismic Category I requirements, with the following exceptions. The moderate energy spray shields have structural supports that are designed to Seismic Category I, however, the shielding is constructed of a plastic type material and as such has no seismic pedigree. Architectural features (e.g. doors), tornado dampers, HELB mitigation dampers, ductwork, penetration seals, and backwater valves of the floor drain system are non-seismic category I. (Although some backwater valves are credited to operate for the mitigation of postulated piping failures, a seismic event is not assumed in the analysis of these failures.) Primary plant ventilation (Section 9.4.3) supply (Figure 9.4-9, Sh. 3) and associated chilled water (Section 9.4E) are non-seismic category I. Also see Section 7.6.12 for detection and mitigation equipment exceptions.

3.6B.2 DETERMINATION OF BREAK LOCATIONS AND DYNAMIC EFFECTS ASSOCIATED WITH THE POSTULATED RUPTURE OF PIPING (INSIDE AND OUTSIDE CONTAINMENT)

The design bases for locating postulated breaks and cracks in piping inside and outside of the Containment, the procedure used to define the jet thrust reaction at the break or crack location and the jet impingement loading on adjacent structures, equipment, systems, and components are described as follows.

3.6B.2.1 Criteria Used To Define Break And Crack Location And Configuration

This section provides criteria for the location and configuration of postulated pipe breaks in high energy piping systems.

3.6B.2.1.1 Reactor Coolant System (RCS) Main Loop Piping

The generic Leak-Before-Break technology described in NUREG-1061 Volume 3 [18] has been applied to the CPNPP Units 1 and 2 RCS main loop piping.

This application of Leak-Before-Break methodology, allowed under the modified GDC-4, is discussed in reference [19].

The analyses show that the probability of RCS main loop piping breaks is extremely low, thus the dynamic effects of these breaks are not considered in the design basis of CPNPP. CPNPP leak-before-break was developed from detailed analysis of the following factors [19]:

1. The loads, material properties, transients, and geometry for CPNPP Units 1 and 2 RCS primary loop are enveloped by the Westinghouse generic leak-before-break analyses.

2. Stress corrosion cracking is precluded by use of fracture resistant materials in the piping system and controls on reactor coolant chemistry, temperature, pressure, and flow during normal operation.

3. Water hammer is precluded in the RCS primary loop piping because of system design, testing, and operational considerations.

4. The effects of low and high cycle fatigue on the integrity of the primary piping are negligible.

5. Ample margin exists between the leak rate of the reference flaw and the criteria of Reg. Guide 1.45. (See FSAR Sections 1A(B) and 5.2.5).

6. Ample margin exists between the reference flaw chosen for leak detectability and the “critical” flaw.

7. Ample margin exists in the material properties used to demonstrate end-of-life (relative to aging) stability of the reference flaw.

The reference flaw will be stable throughout reactor life because of the ample margins in e, f, and g, above and will leak at a detectable rate which will assure a safe plant shutdown.

Although the dynamic effects of the RCS main loop piping breaks are not considered in the design basis, GDC 4 (FSAR Section 3.1.1.4) requires that primary coolant piping breaks be included in the design of the reactor containment, the ECCS, and in environmental qualification. In order to comply with this requirement, main loop breaks are postulated as discussed in Sections 6.2, 6.3 and 3.11 respectively.

The new Leak Before Break (LBB) leak rate calculation methodology for Alloy 82/182 welds with Structural Weld Overlay (SWOL), has been approved by the Nuclear Regulatory Commission for use in Pressurizer Surge Line (PSL) LBB analysis at the Waterford nuclear power plant. This methodology is applicable for CPNPP and has been utilized for the LBB analysis for Alloy 82/182 welds with SWOL for the pressurize surge line nozzle.

3.6B.2.1.2 High Energy Piping Other Than The RCS Main Loop

High energy fluid systems are those systems that during normal plant conditions are either in operation or maintained pressurized under conditions where either or both of the following are met:

Maximum operating temperature exceeds 200°F

Maximum operating pressure exceeds 275 psig.

It is noted that systems which operate within the pressure and temperature conditions specified for high energy fluid systems for less than two percent (2%) of the time are considered moderate energy. Breaks for these systems are postulated as described in Section 3.6B.2.1.4. A list of high energy lines is given in Table 3.6B-1.

Design basis break locations and types are postulated in accordance with NRC Regulatory Guide 1.46 and Branch Technical Position MEB 3-1. Where required, postulated pipe breaks are selected as described below and analyzed to demonstrate the capability for a safe shutdown of the plant.

Application of leak before break methodology justifies the elimination of postulated pipe ruptures in 10 inch and larger RCS branch lines. This analysis demonstrates the piping integrity and serves as the basis for excluding from consideration the dynamic effects associated with postulated pipe ruptures.

1. ASME Section III, Code Class 1 Piping (Excluding Primary Reactor Coolant Loop Piping)

   For high energy piping in the RC, CVC, RHR, and SI systems, the 1977 Edition up to and including Summer 1979 Addenda of ASME B&PV Code Section III, Code Class 1 will be used to postulate pipe breaks. For all other high energy piping the 1974 Edition up to and including Winter 1975 Addenda is applicable. The pipe breaks are postulated to occur at terminal ends and at all intermediate locations in the piping system where none of the following criteria is met:

   a. The primary plus secondary stress intensity range (equation (10) of ASME III Subparagraph NB-3653) derived on an elastically calculated basis under loadings associated with the OBE and normal and upset plant conditions does not exceed 2.4 S_m or

   b. The primary plus secondary stress intensity range derived on an elastically calculated basis under loadings associated with the OBE and normal and upset plant conditions exceeds 2.4 S_m but is less than 3.0 S_m, and the cumulative usage factor is less than 0.1 or

   c. The primary plus secondary stress intensity range derived on an elastically calculated basis under loadings associated with the OBE and normal and upset plant conditions exceeds 3.0 S_m but the stress ranges computed by Equations (12) and (13) of Subparagraph NB-3653 of ASME III are less than 2.4 S_m and the cumulative usage factor is less than 0.1.

2. ASME Section III, Code Class 2 and 3 Piping

   ASME B&PV Code, Section III, Class 2 and Class 3 piping breaks are postulated to occur at terminal ends and intermediate locations in each piping run or branch run. Breaks at intermediate locations are selected by either of the following criteria:

   a. At each location where the stresses associated with normal and upset plant conditions and an OBE event, calculated by the sum of Equations (9) and (10) of paragraph NC-3652 of the ASME B&PV Code, Section III, exceed 0.8(1.2 S_h+S_A).

b. Certain pipe runs contain Class 2 piping extensions to Class 1 lines up to the first anchor point beyond the Class 1/Class 2 boundary. For these pipe runs a break is postulated at the Class 2 terminal end. Breaks are not postulated in the Class 2 portion if the stresses in the Class 1 portion, calculated using Equation (10) of NB-3653, are above 2.4 S_m and the sum of the stresses in the Class 2 portion calculated using Equations (9) and (10) of NC- 3652, are below 0.8 (1.2 S_h + S_A).

3. Non-Nuclear Piping

Breaks are postulated to occur in non-nuclear piping systems at the locations as specified for ASME Section III, Class 2 and 3 piping in accordance with Section B criteria above when a seismic stress analysis is performed.

Breaks in non-nuclear piping systems are postulated at terminal ends and at intermediate points, such as fittings (elbows, tees, reducers, etc.), welded attachments and valves in each run or branch run where a stress analysis is not performed.

4. Fluid System Piping Between Containment Isolation Valves

There are no ASME Section III, Class I piping penetrations. The piping between containment Isolation valves is ASME B&PV Code, Section III, Class 2 piping.

Breaks are not postulated in the break exclusion areas of high energy fluid system piping from the inside containment process pipe-to-penetration weld to and including the outside containment isolation valve moment restraint forging as shown on Figures 3.6B-15, 16, 17, 18, 23, 25, 26, 27, 28, 29, 30, 42, 82, 85, 87 and 88. Moment restraints/forgings are provided to protect the containment isolation valves, process pipes and penetrations within the break exclusion areas. A typical moment restraint/forging, including the boundaries of the break exclusion area, is shown in Figure 3.6B-5.

The following stress limits of Branch Technical Positions APCSB 3-1 [3] and MEB 3-1 [2] for ASME B&PV Code, Section III, Class 2 piping are met within the break exclusion areas:

a. The maximum stress ranges as calculated by the sum of Equations (9) and (10), paragraph NC-3652 of the ASME B&PV Code, Section III, considering normal and upset plant conditions (i.e., sustained loads, occasional loads, and thermal expansion), and an OBE event do not exceed 0.8 ($1.2S_h$+ S_A).

b. The maximum stress, as calculated by Equation (9), paragraph NC-3652 of the ASME B&PV Code, Section III, under the loadings resulting from a postulated piping failure beyond the break exclusion area, does not exceed 1.8 S_h. The moment restraint forging is permitted higher stresses outboard of the restrained locations provided a plastic hinge is not formed.

Welded attachments, for pipe supports or other purposes, to these portions of piping are avoided except where detailed stress analyses or tests are performed to demonstrate compliance with the limits defined in 4.a and 4.b above. In

addition, the number of circumferential and longitudinal piping welds and branch connections is minimized. Guard pipes are not used.

The length of these portions of piping is reduced to the minimum length practical. The design of pipe anchors or restraints (e.g., connections to Containment penetrations and pipe whip restraints) does not require welding directly to the outer surface of the piping (e.g., flued-integrally forged pipe fittings are used). If welded attachments are required, such welds are 100-percent volumetrically examinable in service, and a detailed stress analysis shall be performed to demonstrate compliance with the limits defined in 4.a and 4.b above.

3.6B.2.1.3 Type of Breaks Postulated in Fluid System Piping Other Than the RCS Main Loop

Circumferential and longitudinal breaks are postulated in piping systems at locations previously discussed. The following are definitions and criteria used to determine the type of break to be considered:

1. Circumferential Pipe Breaks

Circumferential breaks are defined as a full cross section area break, with at least one diameter lateral displacement of the ruptured pipe. Circumferential breaks are postulated in piping with nominal size greater than 1", unless the break separation is physically limited by piping restraints, by structural members, or by piping stiffness as demonstrated by inelastic limit analysis. Circumferential breaks are perpendicular to the pipe axis, and the break area is equivalent to the internal cross-sectional area of the ruptured pipe. Dynamic forces at the break location are based on a calculated fluid pressure as modified by an analytically or experimentally determined thrust coefficient. These forces separate the piping axially causing the ruptured pipes to move in the direction of the thrust force. The ruptured pipe is assumed to whip in the plane defined by the piping geometry and configuration causing the pipe to move in the direction of the jet reaction.

Only circumferential breaks are postulated at terminal points, whether or not the piping is seamless. For a terminal point at an equipment or vessel nozzle, a circumferential break is postulated at the pipe-to-nozzle weld. If the terminal point is at a normally closed valve pressurized on one side, the circumferential break is at the pipe-to-valve weld on the high energy side. For a terminal point where a fitting is installed, a circumferential pipe break is postulated only at terminal-to-fitting weld. The pipe-to-fitting weld (the second weld on fitting) may be used as an intermediate pipe break if required by stress level.

2. Longitudinal Pipe Breaks

Longitudinal breaks are assumed to result in an axial split of the pipe without severance. Splits are oriented (but not concurrently) at two diametrically opposed points on the piping circumference so that a jet reaction causing out-of-plane bending of the piping configuration results. Alternatively, a single split may be assumed at the section of highest tensile stress as determined by an elastic stress analysis.

Longitudinal breaks in high energy fluid system piping are postulated in nominal pipe sizes 4-inches and larger. Longitudinal breaks are not postulated at terminal ends. The provision for longitudinal breaks at terminal points applies not only to anchored points, but

also to terminal points at branch connections and at the point immediately outboard of the break exclusion area. Longitudinal breaks are also not postulated at intermediate locations where the criterion for the minimum number of breaks as described in Sections 3.6B.2.1.2.1 and 3.6B.2.1.2.1 is satisfied.

If a detailed stress analysis or test is performed the results may be used to predict the most probable rupture location(s) for the longitudinal breaks. Without the benefit of the stress analysis report, longitudinal breaks will be postulated to occur on each side of a fitting.

Only one type of break need be postulated at a location based on the stresses as identified by a stress analysis. If the primary plus secondary stress in the axial direction is found to be at least 1.5 times that in the circumferential direction for the most severe normal plus upset loading combination, then only a circumferential break need be postulated. Conversely, if the primary plus secondary stress in the circumferential direction is found to be at least 1.5 times that in the axial direction for the most severe loading combination noted above, then only a longitudinal break need be postulated.

The dynamic force of the fluid jet discharge is based on a circular break area equal to the effective cross-sectional flow area of the pipe at the break location and on a calculated fluid pressure modified by an analytically or experimentally determined thrust coefficient as determined for a circumferential break at the same location.

Piping movement is assumed to occur in the direction of the jet reaction unless limited by structural members, piping restraints, or piping stiffness as demonstrated by inelastic limit analysis.

3.6B.2.1.4 Moderate Energy Piping

Moderate-energy fluid systems are the fluid systems that during normal plant conditions are either in normal operation or maintained pressurized under conditions where both of the following are met:

Maximum operating temperature is 200°F or less

Maximum operating pressure is 275 psig or less

Through-wall leakage cracks are postulated for moderate energy piping systems inside and outside the containment in accordance with the following criteria:

1. Through wall leakage cracks are postulated either at any location in moderate energy piping larger than 1 inch, where essential equipment may be affected by the environmental effects from fluid spray and flooding or only where the stresses associated with normal and upset plant conditions and an OBE event as calculated by the sum of equations (9) and (10) of paragraph NC-3652 of the ASME B&PV Code, Section III exceed .4 ($1.2\ S_h + S_a$).

2. Fluid flow from a crack is based on a circular opening of area equal to that of a rectangle which is one-half pipe internal diameter in length and one-half pipe wall thickness in width.

3. Cracks instead of breaks are postulated in the piping of those fluid systems that qualify as high energy fluid systems for only short operational periods, but qualify as moderate energy fluid systems for the major operational period.

   An operational period is considered short if the fraction of time that the system operates within the pressure-temperature conditions specified for high energy fluid systems is less than two percent (2%) of the time that the system operates as a moderate energy fluid system.

   Where through wall leakage cracks are postulated in one of two or more redundant trains of a dual-purpose moderate-energy essential system (i.e., one train required to operate during normal plant conditions as well as to shut down the reactor and mitigate the consequences of the piping failure), single failures of components in the other train or trains of that system are not assumed provided the system is designed to seismic Category I standards, is powered from both offsite and onsite power sources, and is constructed, operated, and inspected to quality assurance, testing, and inservice inspection standards appropriate for nuclear safety systems.

3.6B.2.1.5 Definition of Plant Operating Conditions

Plant operating conditions which are used in calculating the stresses for ASME Section III piping to establish pipe break locations are as follows:

1. Normal Plant Conditions

   Plant operating conditions during reactor startup, operation at power, hot standby, or reactor cooldown to cold shutdown condition.

2. Upset Plant Conditions

   Plant operating conditions during system transients that may occur with moderate frequency during plant service life and are anticipated operational occurrences, but not during system testing.

3.6B.2.2 Analytical Methods to Define Forcing Functions and Response Models

The analytical methods used to define the forcing functions and the response models are described in the following sections.

3.6B.2.2.1 Reactor Coolant System Main Loop Piping

In order to determine the thrust and reactive force loads to be applied to the reactor coolant loops during the postulated loss of coolant accident (LOCA), it is necessary to have a detailed description of the hydraulic transient. Hydraulic forcing functions are calculated for the ruptured and intact reactor coolant loops as a result of a postulated LOCA. These forces result from the transient flow and pressure histories in the RCS. The calculation is performed in two steps. The

first step is to calculate the transient pressure, mass flow rates, and thermodynamic properties as a function of time. The second step uses the results obtained from the hydraulic analysis along with input of areas and direction coordinates and calculates the time history of forces at appropriate locations in the reactor coolant loops.

The hydraulic model represents the behavior of the coolant fluid within the entire RCS. Key parameters calculated by the hydraulic model are pressure, mass flow rate, and fluid density. These are input to the thrust calculation, with appropriate plant layout information, to determine the time-dependent loads exerted by the fluid on the loops. In evaluating the hydraulic forcing functions during a postulated LOCA, the pressure and momentum flux terms are dominant. The inertia and gravitational terms are taken into account in evaluation of the local fluid conditions in the hydraulic mode.

The blowdown hydraulic analysis is required to provide the basic information concerning the dynamic behavior of the reactor core environment for the loop forces, reactor kinetics and core cooling analysis. This requires the ability to predict the flow, quality, and pressure of the fluid throughout the reactor system. The SATAN-IV code [11] was developed with a capability to provide this information.

1. Unit 1

   The MULTIFLEX 3.0 [42] computer code was developed with this capability, which is an enhancement and extension of MULTIFLEX 1.0 [37] NRC reviewed and approved computer code developed for the space-time dependent analysis of nuclear power plants. The MULTIFLEX 3.0 features which differ from MULTIFLEX 1.0 are primarily related to vessel forces. The loop forcing functions do not differ significantly from those generated using the NRC approved MULTIFLEX 1.0 model. MULTIFLEX 3.0 has been accepted by the NRC for several other applications [38, 39, 40 and 41] and also has been extensively used for the LOCA analyses of reactor internals components of numerous other 2, 3, and 4 loop nuclear power plants.

   MULTIFLEX is a digital computer program for calculation of pressure, velocity and force transients in reactor primary coolant systems during the subcooled, transition and the early saturation portion of blowdown caused by a LOCA. During this phase of the accident, large amplitude rarefaction waves are propagated through the system with the velocity of sound causing large differences in local pressures. As local pressures drop below saturation, causing the formation of steam, the amplitudes and velocities of these waves drastically decrease. Therefore, the largest forces across the loop piping due to wave propagation occur during the subcooled portions of the blowdown transient. MULTIFLEX includes mechanical structure models and their interaction with the thermal-hydraulic system, although these features are only involved in the vessel and steam generator modeling.

2. Unit 2

The SATAN-IV code performs a comprehensive space time-dependent analysis of a LOCA and is designed to treat all phases of the blowdown. The stages are:

1. A subcooled stage where the rapidly changing pressure gradients in the subcooled fluid exerts an influence upon the RCS internals and support structures

2. A two phase depressurization stage

3. The saturated stage.

The code employs a one dimensional analysis in which the entire RCS is divided into control volumes. The fluid properties are considered uniform and thermodynamic equilibrium is assumed in each element. Pump characteristics, pump coastdown and cavitation, core and steam generator heat transfer, including the W-3 departure from nucleate boiling (DNB) correlation, and reactor kinetics are incorporated in the code.

The THRUST (Unit 1) or STHRUST (Unit 2) computer programs [12] were developed to compute the transient (blowdown) hydraulic loads resulting from a LOCA.

The blowdown hydraulic loads on primary loop components are computed from the equation

$$F = 144A\left[\frac{(P - 14.7) + (m^2)}{144\rho\ g\ A^2 m}\right]$$

which includes both the static and dynamic effects. The symbols and units are:

F = force (lb_f)

A = aperture area (ft^2)

P = system pressure (psig)

m = mass flow rate (lbm/sec)

ρ = density (lb_m/ft^3)

g = gravitational constant (32.174 ft-$lb_m/lb_f sec^{2)}$

A_m = mass flow area (ft^2)

In the model to compute forcing functions the reactor coolant loop system is represented by a similar model as employed in the blowdown analysis. The entire loop layout is described in a global coordinate system. Each node is fully described by blowdown hydraulic information and the orientation of the streamlines of the force nodes in the system. These include flow area and projection coefficients along the three axes of the global coordinate system. Each node is modeled as a separate control volume, with one or two flow apertures associated with it. Two apertures are used to simulate a change in flow direction and area. Each force is divided into its x, y, and z components using the projection coefficients. The force components are then summed over the total number of apertures in any one node to give a total x force, total y force, and total z force. These thrust forces serve as input to the piping/restraint dynamic analysis described in Section 3.9N.14.

3.6B.2.2.2 High-Energy Piping Other Than RCS Main Loop

The time dependent function representing the thrust forces caused by the jet flow from a postulated pipe break or crack includes the combined effects of the thrust impulse resulting from the sudden pressure drop at the initial moment of pipe rupture, the thrust transient resulting from wave propagation and reflection, and the blowdown thrust resulting from buildup of the discharge flow rate which may reach steady state if there is a fluid energy reservoir having sufficient capacity to develop a steady jet for a significant interval. Alternatively, in a simplified method, the jet thrust force is represented by a steady state function. This function, representing the force, would have a magnitude not less than:

$$F_{ss} = C_t PA$$

where:

F_{ss} = steady state thrust force (lb_f)

P = system pressure prior to pipe break (lb_f/in^2)

A = pipe break area (in^2)

C_t = steady state thrust coefficient

The steady state thrust coefficient C_t is dependent on the fluid state and the frictional loss terms. The value of steady state thrust coefficient and the time to reach steady state flow conditions are calculated from references [15], [16] and [22].

The rigorous time dependent blowdown forces resulting from a postulated pipe rupture are determined using the RELAP-5 computer code [6 or 34] except where STEHAM [28] is used as part of the alternative dynamic methodology for postulated main steam line breaks described later in this section. RELAP-5 is a thermal/hydraulic program commonly used in the nuclear industry to evaluate the behavior of water cooled reactor systems during postulated accidents such as pipe ruptures. The program is acceptable (see Reference [7]) as a means of determining the hydraulic forcing function at the pipe break. CALPLOTF-III [20] or REPIPE [29] or other post processor programs to the RELAP program are used to develop the break force time-history plots.

The RELAP-5 program solves the transient energy, momentum, and fluid state equations to determine the system flow, pressure, and thermodynamic conditions. The break force is computed using the one-dimensional momentum equation and the appropriate density, internal energy, and pressure values. The rupture load is the summation of the pressure, momentum, and change in momentum terms at the time interval in question.

RELAP-5 has the capability of solving the fluid state equation for subcooled water, flashing water, two-phase steam/water mixtures, and superheated steam. The ASME steam tables [9] have been incorporated into RELAP-5 so that the fluid state properties are accurately determined. RELAP-5 has a provision for modeling components such as valves, check valves, pumps, heat exchangers, and reactors along with the associated piping.

Transients can be initiated by the control card added to the program which is used to describe leaks (pipe breaks), valves opening and closing, check valve pressure drop-flow-characteristics, pump coastdowns, and so forth.

The flow system is described as a series of volumes connected by flow paths or junctions. RELAP-5 requires input data that completely describe the thermodynamic conditions and physical data of the system being analyzed. Pressure, temperature, and flow conditions along with physical dimensions, flow areas, friction characteristics must all be specified as initial conditions. The break area can be reduced by an analytically or experimentally derived discharge coefficient. However, in lieu of such data it is conservatively assumed that the discharge coefficient is 1.0 for both longitudinal and circumferential breaks. In a similar manner, the break area is assumed to open within one millisecond (0.001 second).

Rigorous time dependent blowdown forces and pipe segment forces resulting from the postulated breaks were also determined by using the STEHAM computer program. The analysis is based on the method of characteristics with finite difference approximations both in space and in time. STEHAM calculates the one-dimensional transient flow responses and the flow-induced forcing functions in a piping system caused by rapid operational changing of piping components, such as the stop valve and the safety/relief valve which are used to represent pipe break. Flow characteristics of piping components are mathematically formulated as boundary condition and frictional effects are appropriately taken into consideration in this computer program. Output from STEHAM consists of time-histories of flow pressures, flow densities, flow velocities, inertia, and momentum functions. CHPLOT [32] program is used to plot the force time-history data developed by STEHAM. These data are used as input to the LIMITA3 structural computer program.

The piping dynamic responses resulting from a postulated pipe rupture are determined using the PIPERUP [13], SHPLAST 2267 [24], ABAQUS [21], ANSYS [30 or 35] or LIMITA3 [31] computer codes. The programs are adaptations of the finite element method to the requirements of pipe rupture analyses. They perform a dynamic, nonlinear, elastic-plastic analysis of piping systems subjected to time-history forcing functions. These forces result from fluid jet thrust at the location of a postulated longitudinal or circumferential rupture of high energy piping and ensuing acoustic disturbances within the piping.

The piping is mathematically modeled in the PIPERUP, SHPLAST 2267, ABAQUS, ANSYS or LIMITA3 program as an assembly of weightless structural members connecting discrete nodal points. A typical pipe whip mathematical model is shown in Figure 3.6B-6. Weight of the system, including distributed weight of the piping and concentrated weights (e.g., valves), is lumped at selected mass points (lumped parameter analysis model). Nodal points are placed in such a manner as to isolate particular types of piping elements such as straight runs of pipe, valves, elbows, etc. for which force-deformation characteristics may be determined. Nodal points are also placed at all discontinuities such as piping restraints, branch lines, and changes in cross-section. Piping restraints are modeled with an initial gap and in PIPERUP with a bilinear stiffness curve, or, in SHPLAST 2267, ABAQUS, ANSYS and LIMITA3 with multilinear stiffness curve. A typical piping stress-strain curve is shown in Figure 3.6B-7. The first stiffness represents linear elastic behavior and the second stiffness models linear strain hardening behavior. All five programs utilize a direct step-by-step integration method to determine the time history response of the ruptured piping system. A typical restraint impact curve is shown in Figure 3.6B-8. An incremental procedure is used to account for the nonlinear deformation and elastic-plastic effect of the pipe and restraints.

3.6B.2.3 Dynamic Analysis Methods to Verify Integrity and Operability

3.6B.2.3.1 Reactor Coolant System Main Loop

The leak-before-break technology has been applied to CPNPP Units 1 and 2 to exclude from the design basis the dynamic effects of postulated ruptures in the RCS main loop piping. This applies, in particular, to jet impingement loads on components and supports.

Jet loads from large branch nozzle breaks are addressed in Section 3.6B.2.3.2.

3.6B.2.3.2 High-Energy Piping Other than the RCS Main Loop

Pipe beaks are postulated in high-energy piping in accordance with the criteria in Section 3.6B.2.1.2. The analyses for determining the dynamic effects of pipe break are as follows:

1. Jet Impingement

   A circumferential or longitudinal break in a high energy line results in a jet of fluid emanating from the break point. For subcooled high energy lines where the fluid temperature is less than its saturation temperature at the surrounding environmental pressure, the discharge jet is characterized by a nearly constant diameter jet approximately equal to the break diameter. Since the fluid temperature is below saturation it will not flash but instead will form an incompressible fluid jet.

   In general, most of the high energy line breaks result in a two-phase choked (critical) flow at the break exit plane. Fluid pressure at the exit plane is in general at some pressure greater than ambient. As the fluid leaves the pipe break area, it expands as the jet pressure decreases from the higher exit (break) plane pressure to the atmospheric pressure surrounding the jet.

   A jet discharging from a saturated steam line will accelerate and expand due to the pressure differential, and it will partially condense to a low-moisture wet steam with the liquid phase in the form of dispersed, entrained water droplets. A jet discharging from a subcooled or saturated hot water line (greater than 212°F) will flash to a low quality wet steam. The flashing will cause the jet diameter to expand very rapidly.

   ANSI/ANS-58.2-1988 [22] provides an acceptable basis (including conservative analytical models) for the evaluation of jet impingement loads. The CPNPP jet impingement methodologies and models are consistent with ANSI/ANS 58.2-1988, as briefly described in the following sections:

   a. Jet Category and Geometry

      The area of the break is assumed to be equal to the flow area of the ruptured pipe. All the high energy line break jets can be summarized into the following three categories:

      1. Category I Jets - Non-Expanding Jets

For the liquid jets whose temperature is below the saturation temperature at ambient pressure, the initial free expansion does not occur. Incompressible liquid jets are assumed to travel with no increase in jet area. However, for target identification a conservative zone of influence of two diameters is utilized. The pressure is assumed to be uniform throughout the jet area.

2. Category II Jets - Steam and Flashing Water Jets which meet the Criteria of NUREG/CR-2913[25]:

The high energy two-phase jet is a complicated multidimensional flow phenomena. The high pressure and high temperature fluid that exits the break expands with supersonic velocities downstream of the break. Upon encountering a target (or obstacle) a shock wave forms in the flow field, and it is the thermodynamic properties downstream of this shock that determine the pressure field and load on the target. A multidimensional analysis, such as demonstrated in NUREG/CR-2913 [25], more realistically evaluates the thermodynamic properties of these jets. The jet cone shape for these Category II jets is a function of the break initial conditions (i.e., temperature and pressure). These jet shapes are determined by using the NUREG/CR-2913 contour curves and are used to establish the jet zone of influence for target identification. The NUREG/CR-2913 model provides a method for calculating target loads for initial pipe rupture fluid conditions of pressure between 60 and 170 bars (870 psia -2466 psia) and with subcooling of 0°C (0°F) to 70°C (126°F). Note that, for Category II jets, the jet shape from the break exit to the jet core region is not defined in NUREG/CR-2913 [25] and should be computed from ANSI/ANS-58.2-1988 [22] (see next section).

3. Category III Jets - All other steam and flashing water jets:

Category III jets are assumed to expand as a three region cone defined in Figure 3.6B-96A for circumferential breaks and Figure 3.6B-96B for longitudinal breaks [22].

(a) Circumferential Break with Full Separation:

Jet Region 1 ($L < L_c$). Region 1 includes a cone-shaped region containing the jet core and the remainder of the jet. This geometry is shown in Figure 3.6B-96C.

The jet core length is related to the jet subcooling at the jet break plane and has been correlated using the following expression

$$L_c/D_e = 0.26 \quad (\Delta T_{sub})^{1/2} + 0.5 \qquad (1)$$

where:

L_c = core length

D_e = pipe inside diameter

T_{sub} = jet subcooling at stagnation conditions in °F at the break plane

Figure 3.6B-96D can be used to relate jet stagnation subcooling at the break plane to stagnation conditions in the vessel supplying the jet flow, accounting for irreversible losses in the blowdown line.

In Region 1, for $0 < L < L_c$, the jet core diameter, D_c, is given by

$$D_c/D_e = (C^*_{Te})^{1/2} (1-L/L_c) \quad (2)$$

where:

C^*_{Te} = 2.0 for $\Delta T_{sub} > 0$

1.26 for $\Delta T_{sub} = 0$

L = distance from break plane to target

Jet Region 2 ($L_c < L < L_a$). In Region 2, the jet expands to its asymptotic area which can be calculated as:

$$A_a/A_e = G_e^2/(g_c \rho P_{ma} C_T P_o) \quad (3)$$

where:

A_a = jet area at the asymptotic plane

A_e = break plane area

C_T = steady-state thrust coefficient (as defined in ANSI/ANS-58.2 [22])

G_e = mass flow rate per unit area from the break plane

g_c = gravitational constant

P_o = initial total (stagnation) pressure in the vessel

ρ_{ma} = asymptotic plane density. If two-phase, density will be given by

ρ_{ma} = $1/\lfloor x/\rho_g + (1-x)/\rho_f \rfloor$

x = mixture vapor mass fraction i.e. quality, at the asymptotic plane pressure, Pa, and stagnation enthalpy

ρ_f = saturated liquid density at the asymptotic plane pressure

ρ_g = saturated vapor density at the asymptotic plane pressure

[Note: Figure 3.6B-96E may be used in place of Equation (3)]

The jet pressure at the asymptotic plane, Pa can be expressed as the following expression

$$(Pa)/P_{amb} = 1 - 0.5\,(1 - 2P_{amb}/P_o) f(h_o) \qquad (4)$$

where:

P_{amb} = ambient pressure

Pa = asymptotic plane static pressure

$$f(h_o) = \begin{cases} [0.1 + (h_o - h_f)/h_{fg}]^{1/2} & \text{for } (h_o - h_f)/h_{fg} > -0.1 \\ 0 & \text{for } (h_o - h_f)/h_{fg} < -0.1 \end{cases}$$

h_o = stagnation enthalpy in the vessel[(a)]

h_f, h_{fg} = saturated liquid enthalpy and heat of vaporization in the vessel

---

a) h_o in the vessel and at the break plane are assumed to be equal.

The distance from the break plane to the asymptotic plane is defined by:

$$L_a/D_e = 1/2\left[(A_a/A_e)^{1/2} - 1\right] \qquad (5)$$

The jet area at any location from the break plane to the asymptotic plane (Regions 1 and 2) may be calculated from the following relationship:

$$A_j/A_{je} = \left[1 + L/L_a\,(A_a/A_{je} - 1)\right], \qquad (6)$$

where:

A_j = jet area

A_{je} = jet area at break plane

Jet Region 3 ($L \geq L_a$). In Region 3, the jet area is given by

$$A_j A_a = (1 + (2(L - L_a)/D_a)(\tan 10°))^2 \quad (7)$$

where:

D_a = jet diameter at the asymptotic plane

(b) Longitudinal Break

The jet shape for longitudinal breaks, as shown in Figure 3.6B-96B shall be assumed to be the same as the circumferential break defined in 3.6B.2.3.2.1.a.3.a. A jet diameter for a circular break of the same area may be used and the jet direction taken to be perpendicular to the axis of the pipe.

2. Effective Target Distance

a. Category II Jets

For steam and flashing water jets within the limits of NUREG/CR-2913 [i.e., stagnation pressure from 60 bars (870 psia) to 170 bars (2466 psia) and subcooling of 0°C (0°F) to 70°C (126°F)] the effective target distance is taken as ten (10) times the inside diameter of the ruptured pipes [25].

b. Category I & III Jets

For all other high energy line break jets, jets are assumed to travel until impact with a target or a barrier.

3. Jet Force and Pressure

a. Category I Jets

The generalized momentum equation that describes the jet blowdown force, F_b, is;

$$F_b = G^2{}_e A_e/\rho_e g_c + A_e(P_e - P_{amb}) \quad (8)$$

where:

P_e = fluid pressure at the break flow area

ρ_e = fluid density at the break flow area

And for calculating target loads a conservative quasi-steady-state jet force, F_j, is used:

$$F_j = A_e (C_T P_o - P_{amb}) - C_T P_o A_e \quad (9)$$

However, the above equation for F_j is modified as follows:

1. For jets where $\Delta T_{sub} > 0$, C_T is multiplied by $(2.0/C_{Te})$ in region 1, where $C_{Te} = C_T$ based on FL/D=O and the break plane stagnation condition.

2. Unless otherwise justified, F_j is not to be less than the initial jet force based on equation (8).

For liquid jets whose temperature is below the saturation temperature at ambient pressure, a uniform pressure over the jet cross-section can be assumed, which is consistent with the jet area and the total jet force as defined by equation (8) or (9).

b. Category II Jets

In NUREG/CR-2913 [25], an advanced two-dimensional computer code (CSQ) was used to develop a two-phase jet load data base. The results showed that the jet force/pressure can be expressed as functions of four independent variables:

$F_j = F_j(r/D_e, L/D_e, P_o, T_o, \text{or } X_o)$ and

$P_j = P_j(r/D_e, L/D_e, P_o, T_o, \text{or } X_o)$

where:

r = radial distance from the jet center line

T_o = stagnation temperature in the vessel

X_o = stagnation quality in the vessel

P_j = radial pressure distribution on and an area perpendicular to the jet centerline

The values of F_j and P_j corresponding to some specific conditions of r/D_e, L/D_e, P_o, T_o or X_o can be found in NUREG/CR-2913 [25].

c. Category III Jets

The total jet force defined by Equations (8) and (9) can also be applied to Category III Jets. However, it should be recognized that typical Category III Jets (except low pressure jets which are discussed later) are under expanded, which means that the jet pressure at the break plane is greater than the ambient pressure. The jet expands rapidly as it leaves the break and comes to equilibrium with the surrounding pressure. Therefore, the jet impingement pressure decreases in a radial direction, away from the jet centerline. According to ANSI/ ANS-58.2-1988, the radial pressure distributions in the different jet regions are given below.

1. For Region 1, defined as $0 < L < L_c$, the jet pressure in the core and outside the core is given by

   Jet Core; for $0 < r < D_c/2$,

$$P_j = P_{oe} = \frac{F_j}{A_{je}} \quad = \text{stagnation pressure at the break} \tag{11}$$

   Outside Core; for $D_c/2 < r < D_j/2$,

$$\frac{P_j}{P_{oc}} = \left(\frac{D_j - 2r}{D_j - D_c}\right)\left[1 - \frac{2[D_j^2 + D_j D_c + D_c^2 - 3D_c^2\ C^*_{Te}\ ]}{(D_j^2 - D_c^2\ )}\right] \tag{12a}$$

$$\text{if}\left[(D_j/D_e)^2 + 2(D_j\ D_c/D_e^2\ ) + 3(D_c/D_e)^2\right] > 6C^*_{T_e} \text{ then}$$
$$\frac{P_j}{P_{oe}} = \left(\frac{D_j - 2r}{D_j - D_c}\right)^2\left[\frac{6(D_e^2\ C^*_{T_e} - D_c{}^2)}{(D_j - D_c)(D_j + 3\ D_c)}\right] \tag{12b}$$

2. For Region 2, defined as $L_c < L < L_a$, the jet pressure is given by

$$\frac{P_j}{P_{jc}} = \left(1 - \frac{2r}{D_j}\right)\left[1 - 2\left(\frac{2r}{D_j}\right)\left[1 - 3C_{Te}\left(\frac{D_e}{D_j}\right)^2\left(\frac{P_{oe}}{P_{jc}}\right)\right]\right] \tag{13}$$

   where

$$\frac{P_{jc}}{P_{oe}} = \left[F_c - 3C_{Te}\left(\frac{D_e}{D_a}\right)^2\right]\frac{L_a(L - L_c)}{L(L_a - L_c)} \quad \begin{array}{l}\text{= Jet centerline}\\ \text{pressure for}\\ (L_c<L<L_a)\end{array} \tag{14}$$

   F_c = 1.0 for $(D_j/D_e)^2 < 6C_{Te}^*$ at $L=L_c$

F_c = 6 CTe* $(D_e/D_j)^2$ for $(D_j/D_e)^2 > 6$ C_{Te}* at $L=L_c$

C_{Te} = Steady-state thrust coefficient defined at break plane conditions

3. For Region 3, defined as $L \geq L_a$, the jet pressure is given by

$$\frac{P_j}{P_{jc}} = \frac{D_j - 2r}{D_j} \quad (15)$$

where

Pjc = 3 F_j/A_j, jet centerline pressure for ($L > L_a$) (16)

It should be noted that the above pressure distribution can only be applied to large targets on the jet center line and underexpanded jets. For a small target which is not on the jet center line, judgement should be made to decide if the impingement load can be computed using the jet radial pressure distribution. This is particularly true at the outer edge of the jet where the jet flow may be away from the jet center line and not parallel to it. Additionally, if the stagnation pressure at the break flow area is sufficiently close to the ambient pressure (low pressure jets), the core length, L_c, calculated by equation (1) may be greater than the distance to the asymptotic surface La, calculated by equation (5). For this bounding case, the core length may be set to zero (L_c =0) and the jet pressure distribution assumed to be uniform over the jet cross section and equal to F_j/A_j.

4. Jet Impingement Force

The jet impingement force which is applied to a given target is a function of the fraction of the jet which is intercepted by the target. If the entire jet is intercepted, then the entire jet force is applied to the target.

$$F_{jt} = F_j \quad (17)$$

If the target intercepts a fraction of the jet, but not the entire jet, the jet pressure distribution over the target must be integrated to obtain the jet force.

$$F_{jt} = \int P_j \, dA_t \quad (18)$$

where

P_j = radial jet pressure distribution at the impingement plane, as described in 3.6B.2.3.2.3 above.

A_t = Target area

The impingement load may be estimated from the jet axial force and an approximate correction factor,

$$F_{imp} = K\varphi\ F_{jt}(DLF) \quad (19)$$

where

F_{imp} = impingement force on the target, as a function of time

$K\varphi$ = the shape factor, a measure of the target's potential for changing the momentum of the jet, as described in Appendix D of Reference 22

DLF = Dynamic Load Factor [26]

5. Pipe Whip Dynamic Analysis Criteria

An analysis of the pipe run or branch is performed for each longitudinal and/or circumferential postulated rupture at the break locations determined in accordance with the criteria of Section 3.6B.2.1.2. The loading condition of a pipe run or branch prior to postulated rupture, in terms of internal pressure, temperature and stress state, is assumed to be the condition associated with the normal plant operating condition.

For a circumferential rupture, pipe whip dynamic analyses are only performed for that end (or ends) of the pipe or branch that is connected to a contained fluid energy reservoir having sufficient capacity to develop a jet stream. Dynamic analytical methods used for calculating the piping and piping/restraint system response to the jet thrust developed after a postulated rupture adequately account for the effects of the following:

a. Translational masses (and rotational masses for major components) and stiffness properties of the piping system, restraint system, major components and support walls.

b. Transient forcing function(s) acting on the piping system and jet thrusts on affected structures.

c. Elastic and inelastic deformation of piping and/or restraint.

A 10 percent increase of minimum specified design yield strength (S_y) is used to account for strain rate effects in inelastic nonlinear analyses.

3.6B.2.3.3 Pipe Whip Restraint Design Criteria

1. Design Bases

Pipe whip restraints function primarily as a load carrying member for the low probability occurrence of a pipe break. The restraints are designed for one time use only and function to control the movement of the ruptured pipe. The design basis for the pipe

break event is that of a faulted condition. The restraints and the structure which supports them are analyzed accordingly.

2. Functional Requirements

High-energy pipe whip restraints are designed to ensure that the pipe whip will be eliminated or minimized. On the other hand, the restraints are designed to permit the predicted thermal and seismic movements of the pipes.

3. Design Parameters

After the pipe restraint locations are identified, the following design parameters are determined:

a. Jet thrust force

b. Pipe seismic displacements

c. Pipe thermal displacements

d. Pipe insulation thickness

e. Minimum allowable tolerance between restraint and pipe insulation.

f. Maximum allowable pipe movement.

The jet thrust force and maximum allowable pipe movement are used in the analysis process. Tolerance, insulation, and seismic and thermal movements are used in determining the minimum gap between the restraint and pipe surfaces.

The pipe whip restraints used for the CPNPP project are U-bar, crushable pipe, crushable pad (honeycomb), and elastic hard restraints as shown in Figures 3.6B-1 through 3.6B-4. Existing pipe supports may also be considered as additional hardware capable of providing protection when their use can be analytically justified.

4. Analysis and Design

The maximum allowable design limits for the restraints are as follows:

a. The permanent strain in the metallic ductile materials is limited to fifty percent of the minimum ultimate uniform strain (strain corresponding to the maximum stress point on the appropriate engineering stress-strain curve) based on restraint material tests and/or ASME Code [4].

b. The design limit for crushable pipe restraints longer than three outside pipe diameters is 50 percent of energy absorbing capacity (crushed to 70 percent of inside diameter of pipe).

c. The permissible diameter deformations limit for crushable pipe restraints shorter than two outside pipe diameters is the lesser of D/2 or ASTM where;

D = initial outside diameter of the crushable pipe

ASTM = maximum flattening limit for A106 Gr. B carbon steel pipe as prescribed by ASTM A 530-76.

d. If a crushable material, such as honeycomb, is used, the allowable capacity of crushable material shall be limited to 80% of its rated energy dissipating capacity as determined by dynamic testing, at loading rates within + 50% of the specified design loading rate. The rated energy dissipating capacity shall be taken as not greater than the area under the load-deflection curve. The portion of the curve in which the value of load vs. deflection has departed from the essentially horizontal portion shall not be used.

Typical characteristics of pipe whip restraint components are as follows:

a. Energy absorption members of yielding type restraints are those which, under the influence of the whipping pipe, absorb energy by significant plastic deformation. U-bars, crushable pipe, and crushable pad assemblies, designed with materials having high ultimate strain and relatively high energy absorption capacity, are used in CPNPP.

b. Elastic pipe whip restraints are also used. They are essentially plane frames or space frames. Upon rupture, the energy of the whipping pipe is completely absorbed by the steel restraint structure. Movement of the ruptured pipe is controlled by permitting deformation of the elements of the structural restraints within the elastic range of the material. Existing pipe supports activated during pipe rupture are governed by the criteria applicable to their faulted design rating or other acceptable limits which assures protection is provided such that the effects of the break are mitigated.

c. Restraint connecting members are components which form a direct link between the plastic yielding restraint members and the structure (e.g., clevises, brackets, and pins of a U-bar restraint).

d. Restraint connecting member structural attachments are fasteners which provide the means of securing the restraint connecting members of the structure (e.g., weld attachments and bolts).

e. Structural and civil components are steel and concrete structures which ultimately carry the restraint load (e.g., walls, frames, columns, and beams). A dynamic load factor is considered in the design of these structural and civil components. This factor depends on the natural frequency of these components and the restraint force time history. It is evaluated for each postulated break affecting a specific structural or civil component.

f. The design of the pipe whip restraint is for one time usage.

In designing a restraint, the following three loading conditions are considered:

a. An in-plane (the plane of the U-bar) impact loading at an angle up to 45 degrees from the axis of the U-bar.

b. An out-of-plane (the plane of the U-bar) impact loading at an angle up to 10 degrees from the axis of the U-bar.

c. An impact loading at an angle up to 10 degrees from the normal to the crushable pad/pipe axis.

The materials used in restraint design are selected to ensure ductile behavior. The U-bars are made of SA 479 type 304 annealed stainless steel. The crushable pipes are made of SA 106 Grade B carbon steel. The crushable pads are metallurgically bonded type 304 stainless steel sheets. The elastic restraints are made of ASTM A-588 Grade 50 steel. The other restraint components, such as pins, bolts, and anchors, are designed to remain within their elastic limits.

3.6B.2.4 Guard Pipe Assembly Design Criteria

The CPNPP containment is of single barrier design. Guard pipes are not used in the penetration design.

3.6B.2.5 Material to be Submitted for the Operating License Review

This section presents a summary of the dynamic analyses applicable to high-energy piping systems resulting from postulated pipe breaks. The following information is provided for the various high energy systems in the subparagraphs of this Section:

1. Implementation of the stress criteria as outlined in Section 3.6B.2.1

2. The type, number, and location of postulated breaks on which the dynamic analyses are based.

3. The number and locations of pipe whip restraints required to protect essential systems.

4. The results of the jet thrust, impingement functions, and pipe break analysis as described in Section 3.6B.2.2 and 3.6B.2.3 consistent with Reference [5], where the stress intensity ranges and/or usage factors exceed the criteria of 2.4 Sm and 0.2, respectively.

5. The design adequacy of essential systems and components to ensure that their design-intended functions will not be impaired to an unacceptable level of integrity or operability as the result of high-energy pipe breaks.

6. Description of protective enclosures provided to protect safety-related equipment from the effects of a possible rupture in a high energy fluid piping system, including openings in these enclosures.

The implementation of criteria for inservice inspection is discussed in Section 6.6.8.

3.6B.2.5.1 Reactor Coolant System Main Loop Piping

Table 3.6B-2 and Figure 3.6B-9 identify the RCS main loop break locations. The eight main loop piping and three large branch nozzle break locations (breaks 1 to 11 in Table 3.6B-2 and Figure 3.6B-9) are included in the CPNPP design basis for containment design, ECCS and environmental qualification requirements. These eleven postulated breaks are not part of the design basis for dynamic effects, as discussed in Sections 3.6B.2.1.1 and 3.6B.2.1.2. The two remaining branch nozzle breaks (breaks 12 and 13 in Table 3.6B-2 and Figure 3.6B-9) are included in the design basis for dynamic effects.

Design loading combinations and applicable criteria for ASME Class 1 components and supports are provided in Section 3.9N. The forces associated with rupture of the branch nozzles (12 and 13, Table 3.6B-2) to the reactor coolant loop piping systems are considered in combination with normal operating loads and earthquake loads for the reactor coolant loop design in order to assure continued integrity of vital components and engineered safety features. Pipe rupture loads include not only the jet thrust forces acting on the piping but also jet impingement loads on the primary equipment supports.

Barriers and layout are used to provide protection from pipe whip, blowdown jet and reactive forces. Some of the barriers utilized for protection against pipe whip are as follows. The steam generator compartment walls serve as a barrier between the reactor coolant loops and the containment liner. In addition, the refueling cavity walls, various structural beams, the operating floor, and the steam generator compartment walls enclosed each reactor coolant loop into a separate compartment, thereby preventing an accident, which may occur in any loop, from affecting another loop or the containment liner. The portion of the steam and feedwater lines within the containment have been routed behind barriers which separate these lines from all reactor coolant piping. The barriers described above will withstand loadings caused by jet forces and pipe whip impact forces.

Other than for the Emergency Core Cooling System lines, which must circulate cooling water to the vessel, the engineered safety features are located outside of the steam generator compartment walls. The Emergency Core Cooling System lines which penetrate the steam generator compartment walls are routed around and outside the walls to penetrate the walls in the vicinity of the loop to which they are attached.

3.6B.2.5.2 High-Energy Piping Other Than RCS Main Loop

In this section, a summary is presented giving the results of the detailed stress analysis and, describing methods of protection employed to protect essential equipment against the effects of pipe breaks for the high energy systems outlined in Section 3.6B.1.2.1.

1. Main Steam System

   a. General Description

      The main steam piping inside containment is carbon steel ASME SA-155, Grade KCF 70 material designed in accordance with the ASME Code, Section III, Class 2 criteria. The main steam system inside containment consists of four 32 inch OD (1.25 inch minimum wall thickness) lines running from each steam generator to the containment penetrations.

The main steam piping outside containment from the containment penetrations to the main steam isolation valve moment restraints is the same as the main steam piping inside containment. The piping from the MSIV moment restraints to the high pressure turbine is carbon steel ASME SA-155 Grade KC 70 material designed in accordance with ANSI B31.1 as non-nuclear class piping. These lines are 34 inch OD (1.25 inch minimum wall thickness). The piping connected to the main steam drip pots are of carbon steel material with portions designed in accordance with ANSI B31.1 and ASME Code, Section III, Class 2 criteria. The Class 2 portion of the system consists of ASME SA-333 Grade 6, two inch schedule 80 pipe and the non-nuclear portion of the system consists of ASME SA-106 Grade B, two inch schedule 80 pipe. The location and configuration of the main steam lines with respect to structures, equipment, and other piping are shown on Figures 1.2-8, 1.2-14 and 1.2-25. The criteria described above and as follows is applicable for both Units 1 and 2.

b. Pipe Whip Analysis

Isometrics of the main steam lines inside Containment indicating the location of the highest stress node points, postulated breakpoints, and restraints are provided in Figures 3.6B-11 through 3.6B-14 and 3.6B-100 through 3.6B-103. The systems and equipment necessary to mitigate the consequences of a main steam line break are described in Section 3.6B.1. Breakpoints were postulated at the terminal ends of the piping run and at inter-mediate locations in accordance with the criteria out-lined in Section 3.6B.2.1. The steam generator nozzles and the flued heads at the containment penetrations are considered terminal ends. A circumferential break is postulated to occur at any one of these points. Restraints are provided on each line to prevent impact on essential components. The pipe whip restraints are designed to prevent plastic hinge formation and thereby preclude adverse pipe whip effects.

Isometrics of the main steam lines outside containment indicating the location of postulated breakpoints and restraints are provided in Figures 3.6B-15 through 3.6B-18, and 3.6B-104 through 3.6B-107. Since these lines consist of non-nuclear piping, pipe breaks are postulated at each fitting, valve, or welded attachment. Since these lines are greater than 4 inches in diameter, circumferential or longitudinal breaks are postulated. Pipe whip restraints are provided as necessary that are designed to prevent plastic hinge formation and thereby preclude adverse pipe whip effects. A portion of the main steam lines between the containment penetrations and isolation valves, are designed in accordance with the criteria in Section 3.6B.2.1.2. Therefore, circumferential pipe breaks are not postulated in the regions between the penetrations and the moment restraints after the isolation valves. However, a 1.0 ft^2 crack is postulated and evaluated for environmental effects, in accordance with the criteria in BTP ASB 3-1. As shown on Figures 3.6B-25 and 3.6B-119 through 3.6B-122, pipe breaks are postulated in the main steam blowdown lines outside containment. Since these lines consist of non-nuclear piping, break points are postulated at terminal ends and at each intermediate fitting, valve or welded attachment with the exception of the four break exclusion areas as shown.

Review of the piping layout and plant arrangement showed that breaks in portions of the main steam lines could adversely impact the safeguards, switchgear, electrical and controls and turbine buildings. Accordingly, these lines are restrained as necessary to protect the structures. The pipe whip restraints are designed to prevent plastic hinge formation and thereby preclude adverse pipe whip effects on the structures. Since there are no essential systems or components in the turbine building, protection is primarily provided to protect the structures noted above from a main steam pipe break.

c. Jet Impingement Analysis

The jet impingement analysis for this system is performed to determine the effects of jet impingement loading on essential components (as defined in Section 3.6B.1.2.1), associated supports and building structures.

In those cases where the analysis shows that the component or structure is not capable of withstanding the load then protection is required. Protection consists of either relocating the target, or installing jet shield or barriers to protect the target.

In piping tunnels that contain break exclusion regions of main steam lines, the safety-related equipment in these tunnels are designed to withstand the environmental effects of a non-mechanistic crack with a flow area of 1.0 ft^2. Jets are not generated, and hence jet Loads are not considered in break exclusion regions (superpipe areas).

A small quantity of essential cables is located in the superpipe areas; however, these cables service equipment that because of their function, are appropriately located in these areas. Other essential cables are not located in and do not transit through these areas. The low concentrations of the essential cables located in these areas does not violate the NRC staff's pipe break separation goal for break exclusion areas.

d. Environmental Analysis

The safety-related systems required to mitigate the consequences of a main steam line break inside Containment are designed to perform their safety function under the environmental conditions resulting from a LOCA or MSLB as discussed in Section 3.11.

The penetration area is isolated from the rest of the Safeguards Building by the seismic gap seal between the Safeguards Building and the containment wall, fast closing isolation dampers in the interconnecting HVAC ducts and the pressure resisting watertight doors. These features preclude this crack from producing any detrimental environmental effects on the rest of the plant.

Any one of the main steam lines is postulated to develop a 1 ft^2 crack in the penetration area outside Containment. This crack is postulated to be the most severe break for all rooms, based on the impact to equipment in rooms outside the

break area, the amount of energy released, and the generation of the highest peak. The postulation of this crack is in accordance with Branch Technical Position ASB 3-1.

The only equipment that could be required to operate and that could be in the room where the break occurs are the ventilation dampers. These dampers close on pressure differential; pressure helps keep these dampers closed. The temperature spike will not degrade the ability of these dampers to close and remain closed.

Mass and energy release data were calculated for 100% including power uncertainty, 90%, 80%, 70% and 50% power. Full power including power uncertainty with the 1.0 ft^2 break provided the worst environmental results, i.e., the highest peak temperature. Table 3.6B-4A (Unit 1) and Table 3.6B-4B (Unit 2) provide the mass and energy release data. Mass/energy releases were calculated using a modified version of the LOFTRAN code [33], and it and the related blowdown analysis are plant-specific to CPNPP. LOFTRAN was modified to model the heat transfer which may occur in the uncovered portion of the tube bundle of a steam generator and to calculate the resulting superheated steam mass and energy release. Conservative assumptions were made in order to lead to early tube bundle uncovery, and as a result the earliest superheat initiation time. Primary system temperatures were maximized to increase the primary-to-secondary heat transfer, promoting earlier tube bundle uncovery and maximizing the superheat steam enthalpy following tube bundle uncovery. Table 3.6B-4A and Table 3.6B-4B also provides the time sequence of events based on a 1.0 ft^2 break and an initial power level of 90% including power uncertainty. The environmental analysis used to determine the temperature transient due to this break is described in Section 3.6B.1.2.3.

An Equipment Qualification review of Class 1E equipment in the affected compartment has been performed and Class 1E items have been determined to be qualified for the environment. The Class 1E cables located in the areas affected by the crack are those cables required to support the Class 1E equipment in the same areas. All of these cables are qualified for the LOCA/MSLB inside containment. As such, these cables will remain fully operational throughout this event. Cable separation in these areas meets the requirements of Regulatory Guide 1.75. See Table 3.6B-5 for the remaining safety-related equipment located in the area affected by the steam line break with superheat.

2. Feedwater System

a. General Description

The main feedwater lines inside containment are carbon steel ASME SA-333, Grade 6 material designed in accordance with the ASME Code, Section III, Class 2 criteria. Due to the Unit RSG installation the 18” x 16” reducing elbow material at the RCS nozzle inlet is now SA-508, Grade 2, Class 1. Each of the lines consists of an 18 inch schedule 80 seamless pipe running from the Containment penetration to each steam generator. The main feedwater piping

outside Containment from the containment penetration to the feedwater containment isolation valve is the same as the feedwater piping inside Containment. The piping from the feedwater containment isolation valve to the feedwater control valve moment restraint is also the same as the feedwater piping inside containment, except that these lines are 18 inch schedule 140 seamless pipe. The main feedwater lines from the feedwater control valve moment restraint connect to the main feedwater header combining into one main feedwater line which originates from the feedwater heater in the turbine building. The feedwater lines to the main feedwater header and the feedwater control valve by-pass lines are carbon steel ASME SA-106, Grade B material designed in accordance with ANSI B31.1 as non-nuclear class piping. These lines consist of 18 inch schedule 140 and eight inch schedule 120 pipe. The main feedwater header and feedwater line in the turbine building are carbon steel ASTM A155 Gr KC 60 material designed in accordance with ANSI B31.1 as non-nuclear class piping. These lines are 30 inch OD (2.125 inch minimum wall thickness) pipe. The location and configuration of the feedwater lines with respect to structures, equipment, and other piping are shown in Figures 1.2-8, 1.2-13 and 1.2-25.

The criteria described above and as follows is applicable for both Units 1 and 2.

b. Pipe Whip Analysis

Isometrics of the main feedwater lines inside Containment indicating the location of the highest stress node points, postulated breakpoints, and restraints are provided in Figures 3.6B-19 through 3.6B-22 and 3.6B-108 through 3.6B-111. The systems and equipment necessary to mitigate the consequences of a main feedwater line break are described in Section 3.6B.1. Breakpoints were postulated at the terminal ends of the piping run and at intermediate locations in accordance with the criteria outlined in Section 3.6B.2.1. The flued heads at the containment penetrations and the steam generator nozzles are considered terminal ends. A circumferential break is postulated to occur at any one of these points. Pipe whip restraints are provided as required to prevent impact on essential components. The pipe whip restraints are designed to prevent plastic hinge formation and thereby preclude adverse pipe whip effects. Existing pipe supports were also activated in the pipe whip analysis as additional existing hardware capable of mitigating the effects of the break.

Isometrics of the main feedwater lines outside containment, indicating the location of postulated breakpoints and restraints, are provided in Figures 3.6B-23, 3.6B-24 and 3.6B-112 through 3.6B-118. Since these lines consist largely of non-nuclear piping, pipe breaks are postulated at each fitting, valve, or welded attachment. For all lines, circumferential or longitudinal breaks are postulated. Pipe whip restraints are provided to prevent unacceptable damage to essential components and building structures. The pipe whip restraints are designed to prevent plastic hinge formation to preclude adverse pipe whip effects. A portion of the main feedwater lines between the containment penetrations and the feedwater control valves, is designed in accordance with the criteria in Section 3.6B.2.1.2. Therefore, pipe breaks are not postulated in the regions between the penetrations and the moment restraints after the control valves. However, a one square foot

crack is postulated and evaluated for environmental effects in accordance with the criteria in BTP ASB 3-1.

Review of the piping layout and plant arrangement showed that breaks in portions of the main feedwater lines could adversely impact the safeguards, switchgear, electrical and controls and turbine buildings. Accordingly, these lines are restrained as necessary to protect the structures. The pipe whip restraints are designed to prevent plastic hinge formation and thereby preclude adverse pipe whip effects on the structures. Since there are no essential systems or components in the turbine building, protection is primarily provided to protect the structures noted above from a feedwater line break.

c. Jet Impingement Analysis

The jet impingement analysis for this system is performed to determine the effects of jet impingement loading on essential components (as defined in Section 3.6B.1.2.1), associated supports and building structures.

In those cases where the analysis shows that the component or structure is not capable of withstanding the load then protection is required. Protection consists of either relocating the target, or installing jet shield or barriers to protect the target.

Jet Loads are not considered in break exclusion regions (superpipe areas). A small quantity of essential cables is located in the superpipe areas; however, these cables service equipment that because of their function, are appropriately located in these areas. Other essential cables are not located in and do not transit through these areas. The low concentrations of the essential cables located in these areas does not violate the NRC staff's pipe break separation goal for break exclusion areas.

d. Environmental Analysis

The safety-related systems required to mitigate the consequences of a main feedwater line break inside Containment are designed to perform their safety function under the environmental conditions resulting from a LOCA or MSLB as discussed in Section 3.11.

Any one of the main feedwater lines is postulated to develop a 1 ft^2 crack in the penetration area outside Containment. The postulation of this crack is in accordance with Branch Technical Position ASB 3-1.

The penetration area is isolated from the rest of the safeguards building by the seismic gap seal between the safeguards building and the containment wall, fast closing isolation dampers in the interconnecting HVAC ducts and the pressure resisting watertight doors. These features preclude this crack from producing any detrimental environmental effects on the rest of the plant. High energy flooding is evaluated in the same manner as moderate energy flooding per Section 3.6B.2.5.3.

3. Auxiliary Feedwater System

a. General Description

The Auxiliary Feedwater System lines are carbon steel, ASME SA 106, Grade B and SA 333, Grade 6 material designed in accordance with ASME Code Section III, Class 2 or 3 criteria as applicable. The suction lines of the auxiliary feedwater pumps consist of 10, 8 and 6 inch category 152 piping which is schedule 40, with design pressure of 150 psig. These lines run from the condensate storage tank and service water piping to the suction of each auxiliary feedwater pump. The discharge lines of the auxiliary feedwater pumps consist of 6, 4 and 3 inch category 2002 (category 2003, directly after the isolation valve) piping which is schedule 160 up to 3 inches, and schedule 120 for sizes above 3 inches. The design pressure is 1800 psig. The piping that connects to the main feedwater piping after the last auxiliary feedwater isolation valves is category 1303 which is schedule 80, with a design pressure of 1200 psig to match the main feedwater piping. The discharge lines of the auxiliary feedwater pumps connect to the main feedwater lines. The turbine driven auxiliary feedwater pump discharge piping up to isolation check valves AF-078, AF-106, AF-086, and AF-096 is classified as moderate energy piping since operation as a high energy fluid system is for a limited period as prescribed by 3.6B.2.1.4. The location and configuration of the auxiliary feedwater lines with respect to structures, equipment and other piping are shown in Figure 1.2-10. The criteria described above and as follows are applicable for both Units 1 and 2.

b. Pipe Whip Analysis

Isometrics of the Auxiliary Feedwater System lines indicating the location of the highest stress node points, postulated breakpoints and restraints are provided in Figures 3.6B-26 through 3.6B-33 and 3.6B-124 through 3.6B-130. The systems and equipment necessary to mitigate the consequences of a Auxiliary Feedwater System line break are described in Section 3.6B.1. Breakpoints were postulated at the terminal ends of the piping run and at intermediate locations in accordance with the criteria outlined in Section 3.6B.2.1. Intermediate breaks are postulated as shown. A circumferential break is postulated to occur at each of these points. Pipe whip restraints are provided as required to prevent impact on essential components. The pipe whip restraints are designed to prevent plastic hinge formation and thereby preclude adverse pipe whip effects.

c. Jet Impingement Analysis

The jet impingement analysis for this system is performed to determine the effects of jet impingement loading on essential components (as defined in Section 3.6B.1.2.1), associated supports and building structures.

In those cases where the analysis shows that the component or structure is not capable of withstanding the load then protection is required. Protection consists of either relocating the target, or installing jet shield or barriers to protect the target.

d. Environmental Analysis

The environmental conditions resulting from a break in an Auxiliary Feedwater System line do not affect the operation of safety-related systems required to mitigate the consequences of the accident.

The Auxiliary Feedwater System is high energy only on the basis of the system pressure. During the AFW System operation, for breaks upstream of isolating check valves 1AF-093, 1AF-101, 1AF-083, 1AF-075, 2AF-093, 2AF-101, 2AF-083 and 2AF-075, cold water jets are developed. For breaks downstream of these check valves there exist jets that can produce a steam atmosphere in the feedwater tunnel area. These high temperature jets originate from feedwater during plant warm-up (up to 250°F maximum) (Unit 2 only). The resultant pressure and temperature from these breaks are less severe than those analyzed for this area due to the non-mechanistic one square foot crack of the feedwater piping.

High energy flooding is evaluated in the same manner as moderate energy flooding per Section 3.6B.2.5.3.

4. Auxiliary Steam System

a. General Description

The Auxiliary Steam System Piping is comprised of non-nuclear safety related carbon steel, ASME SA-106 Grade B material. The auxiliary steam system supplies steam to both Units 1 and 2 components.

The steam supply piping to the floor drain waste evaporator package, WPS waste evaporator package, BRS recycle evaporator package and CVCS boric acid batching tank, all located in the Auxiliary Building, are 10, 6, 4 and 2 inch, schedule 40 category 152 Class 5 piping with a design pressure of 150 psig. These lines run from the auxiliary steam header of the components described above and are seismically supported. The return lines of the above components are 2, 1-1/2 and 3/4 inch schedule 40, category 152 Class 5 piping with a design pressure of 150 psig. The return lines are connected to the auxiliary steam drain tank. The location and configuration of the auxiliary steam lines with respect to structures, equipment and other piping are shown in Figures 1.2-31 and 1.2-32.

b. Pipe Whip Analysis

Isometric drawings of the Auxiliary Steam System Piping indicating the locations of the highest stresses, postulated breakpoints and restraints are provided in Figures 3.6B-58 through 3.6B-63. The systems and equipment necessary to mitigate the consequences of an Auxiliary Steam System line break are described in Section 3.6B.1. Break locations were postulated at the terminal ends of the piping run and at intermediate locations in accordance with the criteria outlined in Section 3.6B.2.1. A circumferential break is postulated to occur at each of these points. Pipe whip restraints are provided as required to prevent impact on

essential components. The pipe whip restraints are designed to prevent plastic hinge formation and thereby preclude adverse pipe whip effects.

c. Jet Impingement Analysis

The jet impingement analysis for this system is performed to determine the effects of jet impingement loading on essential components (as defined in Section 3.6B.1.2.1), associated supports and building structures.

In those cases where the analysis shows that the component or structure is not capable of withstanding the load then protection is required. Protection consists of either relocating the target, or installing jet shield or barriers to protect the target.

d. Environmental Analysis

The environmental conditions resulting from a break in an Auxiliary Steam System line do not affect the operation of safety-related systems required to mitigate the consequences of the accident.

The most significant environmental conditions generated by breaks in the auxiliary steam system are the various elevated temperatures. The pressure transients are very slight and do not pose a threat to the safe operation or the structure of the plant. The temperature transients caused by any of the auxiliary system breaks do not affect the safe shutdown of the plant because: 1) equipment required for safe shutdown is located in an area not affected by the break; 2) the equipment is qualified to parameters higher than those experienced during the break; 3) the equipment fails in a safe position; or 4) the equipment has been analyzed to show that the short-duration increased temperatures will not cause appreciable degradation in performance or qualified life.

Blowdown from any of the postulated auxiliary steam system line breaks is terminated automatically. The transients were analyzed for the full period of the blowdown.

Details of the instrumentation required to mitigate the blowdown is in Section 7.6.12.

5. Steam Generator Blowdown Cleanup System

a. General Description

The Steam Generator Blowdown Cleanup System Piping is comprised of non-nuclear safety related, carbon steel ASME SA-106 Grade B material, or non-nuclear safety related stainless steel ASTM A-312 TP 304 or 316 material.

The blowdown lines from each steam generator up to the isolation valve moment restraints are 2", 3" or 4" safety class 2, Schedule 80, category 1303 piping with a design pressure of 1200 psig. The piping connecting the 8-inch header of the steam generator blowdown heat exchanger to the pressure reducing

valve PV-5180 is schedule 80, category 1302, Class 5, with a design pressure of 1200 psig. The portion of the blowdown piping on the Switchgear Building roof is category 1302G, and not seismically supported. The piping from valve PV-5180 up to valve SB-170 is 8-inch, category 302, Class 5, schedule 40, with a design pressure of 450 psig. The piping from valve SB-170 to the filters and demineralizers is 6-inch, category 301, Class 5, schedule 40S with a design pressure of 370 psig. The piping that connects the discharge of relief valve SB020 to the condenser is 4 and 8 inch, category 302, Class 5, Schedule 40, with a design pressure of 450 psig. The piping downstream of the filters is moderate energy piping. The location of the steam generator blowdown cleanup system with respect to structures and equipment are shown in Figures 1.2-31 and 1.2-35.

b. Pipe Whip Analysis

Isometrics of the Steam Generator Blowdown Cleanup System Piping indicating the locations of the highest stresses postulated breakpoints and restraints are provided in Figures 3.6B-38 through 3.6B-45 and 3.6B-136 through 3.6B-144. The systems and equipment necessary to mitigate the consequences of a Steam Generator Blowdown Cleanup System line break are described in Section 3.6B.1. Break locations were postulated at the terminal ends of the piping run and at intermediate locations in accordance with the criteria outlined in Section 3.6B.2.1 except for category 1302G piping, where breaks are postulated at terminal ends and at each intermediate fitting, valve or welded attachment. A circumferential break is postulated to occur at each of these points. Pipe whip restraints are provided as required to prevent impact on essential components. The pipe whip restraints are designed to prevent plastic hinge formation and thereby preclude adverse pipe whip effects.

c. Jet Impingement Analysis

The jet impingement analysis for this system is performed to determine the effects of jet impingement loading on essential components (as defined in Section 3.6B.1.2.1), associated supports and building structures.

In those cases where the analysis shows that the component or structure is not capable of withstanding the load then protection is required. Protection consists of either relocating the target, or installing jet shield or barriers to protect the target.

d. Environmental Analysis

The environmental conditions resulting from a break in a Steam Generator Blowdown System line do not affect the operation of safety-related systems required to mitigate the consequences of the accident.

All equipment required for mitigating the consequences of the accident are located in areas that are isolated from the pipe break event by the automatic closure of HVAC dampers. The leakage that occurs prior to the closure of the dampers has been analyzed and the effects of temperature, pressure and

humidity intrusion evaluated. A total of 20 dampers, 2 in each HVAC duct, are installed and designed to close in a short time after the pipe break occurrence (less than 5 seconds). The dampers are qualified for the transient environmental conditions of the break.

Blowdown from any of the postulated blowdown line breaks is terminated automatically. The transients were analyzed for the full period of the blowdown.

Details of the instrumentation required to mitigate the blowdown is in Section 7.6.12.

High energy flooding is evaluated in the same manner as moderate energy flooding per Section 3.6B.2.5.3.

6. Chemical & Volume Control System

a. General Description

The Chemical and Volume Control System lines are of stainless steel ASME SA-312, TP 304 material or stainless steel ASME SA-312 TP 304 material or stainless steel ASME SA-376 TP 304 material designed in accordance with ASME Code Section III, Class 1, 2 or 3 criteria as applicable. The letdown line from the cold leg of the RCS to the letdown orifices consists of 3 and 2 in category 2501 schedule 160 piping with a design pressure of 2485 psig. The letdown orifices on the low pressure letdown valve PCV-131 is 2 and 3 inch category 601, schedule 40S piping with a design pressure of 700 psig. The letdown line from the low pressure letdown valve to the demineralizers and RHT of the BRS is 3 inch category 301, Schedule 40S, with a design pressure of 370 psig. The suction lines of the charging pumps consist of 1, 2, 3, 4 and 6 inch category 151, schedule 40S piping with a design pressure of 150 psig. These lines run from the volume control tank, CVCS boric acid tank and chemical mixing tank to the suction of the charging pumps. The discharge lines of the charging pumps consist of 4, 3 and 2 inch category 2501 schedule 160 piping, with a design pressure of 2485 psig. These lines run from the charging pumps to the cold leg of the RCS and the RCP seals. The location and configuration of the CVCS lines with respect to structures and equipment are shown in Figures 1.2-11, 1.2-12, 1.2-17, 1.2-18 and 1.2-32.

b. Pipe Whip Analysis

Isometrics of the CVS system piping indicating location of the highest stresses, postulated breakpoints and re-straints are provided in Figures 3.6B-70 through 3.6B-88 and 3.6B-183 through 3.6B-206. The systems and equipment necessary to mitigate the consequences of a CVC system line break are described in Section 3.6B.1. Breakpoints were postulated at the terminal ends of the piping run and at intermediate locations in accordance with the criteria outlined in Section 3.6B.2.1. A circumferential break is postulated to occur at each of these points. Pipe whip restraints are provided as required to prevent impact on essential components. The pipe whip restraints are designed to prevent plastic hinge formation and thereby preclude adverse pipe whip effects.

c. Jet Impingement Analysis

The jet impingement analysis for this system is performed to determine the effects of jet impingement loading on essential components (as defined in Section 3.6B.1.2.1), associated supports and building structures.

In those cases where the analysis shows that the component or structure is not capable of withstanding the load then protection is required. Protection consists of either relocating the target, or installing jet shields or barriers to protect the target.

d. Environmental Analysis

The environmental conditions resulting from a break in an CVC System line do not affect the operation of safety-related systems required to mitigate the consequences of the accident.

The most significant environmental conditions generated by breaks in the CVC system are the various elevated temperatures. The pressure transients are small and do not pose a threat to the safe operation or the structure of the plant. The temperature transients caused by any of the CVCS system breaks do not affect the safe shutdown of the plant because: 1) equipment required for safe shutdown is located in an area not affected by the break; 2) the equipment is qualified to parameters higher than those experienced during the break; 3) the equipment fails in a safe position; or 4) the equipment has been analyzed to show that the short-duration increased temperatures will not cause appreciable degradation in performance or qualified life.

Details of the instrumentation required to mitigate the blowdown is in Section 7.6.12.

High energy flooding is evaluated in the same manner as moderate energy flooding per Section 3.6B.2.5.3.

7. Residual Heat Removal System

a. General Description

The Residual Heat Removal System piping from the RCS hot leg of loop 1 and 4 to the second isolation valve are of stainless steel, ASME SA-376 TP 316 material designed in accordance with ASME Code Section III, Class 1 criteria. These lines consist of 12 inch category 2501, schedule 140 piping with a design pressure of 2485 psig. The piping from the second isolation valve to the containment penetrations is of stainless steel ASME SA-312 TP 304 material designed in accordance with ASME Code section III, Class 2 criteria. These lines are 12 inch category 601, schedule 40S piping with a design pressure of 600 psig. The piping from the containment penetration to the suction of the RHR pumps is of stainless steel ASME SA-358, Class 1. These lines are 16 inch (0.5 inch minimum wall thickness) category 601 with a design pressure of 600 psig. The discharge lines of the Residual Heat Removal pumps are of stainless steel, ASME SA-312

TP 304 material designed in accordance with ASME Code Section III, Class 2 criteria. These lines consist of 8, 10 and 12 inch category 601, schedule 40S piping with a design pressure of 600 psig. The discharge lines of the residual heat removal pumps connect to safety injection system cold leg injection headers. The location of the Residual Heat Removal System piping with respect to structures and equipment is shown in Figures 1.2-10 and 1.2-16.

b. Pipe Whip Analysis

Isometric drawings of the RHR System piping indicating the locations of the highest stresses postulated breakpoints and restraints are provided in Figures 3.6B-64, 3.6B-172 and 3.6B-173. The systems and equipment necessary to mitigate the consequences of a RHR system line break are described in Section 3.6B.1. Breakpoints were postulated at the terminal ends of the piping run and at intermediate locations in accordance with the criteria outlined in Section 3.6B.2.1. A circumferential break is postulated to occur at each of these points. Pipe whip restraints are provided as required to prevent impact on essential components. The pipe whip restraints are designed to prevent plastic hinge formation and thereby preclude adverse pipe whip effects.

c. Jet Impingement Analysis

The jet impingement analysis for this system is performed to determine the effects of jet impingement loading on essential components (as defined in Section 3.6B.1.2.1), associated supports and building structures.

In those cases where the analysis shows that the component or structure is not capable of withstanding the load then protection is required. Protection consists of either relocating the target, or installing jet shield or barriers to protect the target.

d. Environmental Analysis

The RHR System is considered a moderate energy system outside containment in accordance with Branch Technical Position MEB 3-1.

Moderate energy flooding is evaluated in accordance with Section 3.6B.2.5.3.

8. Safety Injection System

a. General Description

The Safety Injection System Piping from the discharge header of the charging pumps to the Reactor Coolant System loop cold legs are stainless steel, ASME SA-376 TP 304 or TP 316 material, designed in accordance with ASME Code Section III, Class 1 or 2 criteria, as applicable. These lines consist of 1, 1-1/2, 2, 3, 4 and 6 inch category 2501, schedule 160 piping with a design pressure of 2485 psig. The piping from the accumulators to the Reactor Coolant System loop cold legs is stainless steel, ASME SA-376 TP 304 or TP 316 material, designed in accordance with ASME Code Section III, Class 1 or 2

criteria, as applicable. These lines are 10 inch category 2501 schedule 140 piping with a design pressure of 2485 psig.

The safety injection pump discharge piping up to the isolation valves outside the containment are stainless steel ASME SA-312 TP 304 or TP 316 material, designed in accordance with ASME Code Section III, Class 2 criteria. These lines consist of 3 and 4 inch category 1501, Schedule 80S piping with a design pressure of 1860 psig. The safety injection pump discharge piping from the isolation valves outside the containment to the Reactor Coolant System hot legs and Safety Injection System cold legs is stainless steel ASME SA-376 TP 304 or TP 316 material, designed in accordance with ASME Code Section III, Class 1 or 2 criteria as applicable. These lines consist of 3/4, 2, 4, 6, 8 and 10 inch category 2501, schedule 160 or 140 piping, as applicable, with a design pressure of 2485 psig. The safety injection pump suction piping is of stainless steel, ASME SA-312, TP 304 or TP 316 material, designed in accordance with ASME Code Section III, Class 2 criteria. These lines consist of 6 and 8 inch category 151 schedule 40S piping with a design pressure of 150 psig. The location of the Safety Injection System piping with respect to structures and equipment are shown in Figures 1.2-10, 1.2-11, 1.2-16 and 1.2-17.

b. Pipe Whip Analysis

Isometric drawings of the Safety Injection System lines indicating the locations of the highest stresses postulated breakpoints and restraints are provided in Figures 3.6B-48 through 3.6B-57 and 3.6B-147 through 3.6B-169. The systems and equipment necessary to mitigate the consequences of a Safety Injection System line break are described in Section 3.6B.1. Breakpoints were postulated at the terminal ends of the piping run and at intermediate locations in accordance with the criteria outlined in Section 3.6B.2.1. A circumferential break is postulated to occur at each of these points. Pipe whip restraints are provided as required to prevent impact on essential components. The pipe whip restraints are designed to prevent plastic hinge formation and thereby preclude adverse pipe whip effects.

c. Jet Impingement Analysis

The jet impingement analysis for this system is performed to determine the effects of jet impingement loading on essential components, associated supports and building structures.

In those cases where the analysis shows that the component or structure is not capable of withstanding the load then protection is required. Protection consists of either relocating the target, or installing jet shield or barriers to protect the target.

d. Environmental Analysis

The environmental conditions resulting from a break in an SI System line do not affect the operation of safety-related systems required to mitigate the consequences of the accident.

Those portions of the Safety Injection System which are considered high energy, outside the containment, are based on the system pressure. The piping is considered as containing cold water so a break in a line cannot generate a steam atmosphere.

High energy flooding is evaluated in the same manner as moderate energy flooding per Section 3.6B.2.5.3.

3.6B.2.5.3 Moderate Energy Piping

In evaluating the effects of a moderate energy system piping failure, the postulated failure is a crack which results in neither pipe whip nor jet impingement but rather in spraying water streams. As such, the consequences are of an environmental/flooding nature. The effects of cracks, as postulated in Section 3.6B.2.1.4, are evaluated for all essential equipment on a case by case basis.

If it is determined that an essential component is not qualified or cannot be demonstrated to operate under the adverse conditions caused by the crack then the essential component is protected. Protection is accomplished either by relocating the component, installing a barrier or curb or by designing a shield.
