Radioactivity doses from the postulated feedwater line rupture are less than those previously presented for the postulated steam line break. All applicable acceptance criteria are therefore met.

15.3 DECREASE IN REACTOR COOLANT SYSTEM FLOW RATE

A number of faults are postulated which could result in a decrease in Reactor Coolant System (RCS) flow rate. These events are discussed in this section. Detailed analyses are presented for the most limiting of these events.

Discussions of the following flow decrease events are presented in Section 15.3:

1. Partial loss of forced reactor coolant flow.

2. Complete loss of forced reactor coolant flow.

3. Reactor coolant pump shaft seizure (locked rotor).

4. Reactor coolant pump shaft break.

Item 1 above is considered to be an American Nuclear Society (ANS) Condition II event, item 2 an ANS Condition III event, and items 3 and 4 ANS Condition IV events. Section 15.0.1 contains a discussion of ANS classifications.

15.3.1 PARTIAL LOSS OF FORCED REACTOR COOLANT FLOW

15.3.1.1 Identification of Causes and Accident Description

A partial loss of coolant flow accident can result from a mechanical or electrical failure in a reactor coolant pump, or from a fault in the power supply to the pump or pumps supplied by a reactor coolant pump bus. If the reactor is at power at the time of the accident, the immediate effect of loss of coolant flow is a rapid increase in the coolant temperature. This increase could result in departure from nucleate boiling (DNB) with subsequent fuel damage if the reactor is not tripped promptly.

Normal power for the pumps is supplied through individual buses connected to the generator. When a generator trip occurs, the buses are automatically transferred to a transformer supplied from external power lines, and the pumps will continue to supply coolant flow to the core. Following any automatic turbine trip where there are no electrical or turbine faults which require tripping the generator from the network, the generator remains connected to the network for approximately 30 seconds. The reactor coolant pump buses remain connected to the network thus ensuring full flow for approximately 30 seconds after the reactor trip before any transfer is made. For a manual turbine trip, or a turbine trip due to certain turbine faults or certain generator protection signals, the generator remains connected to the network for approximately 11.5 seconds. For a complete description of the turbine/generator trip logic, see Figure 7.2-1, Sheet 16 and Figure 10.2-1.

This event is classified as an ANS Condition II incident (a fault of moderate frequency) as defined in Section 15.0.1.

The necessary protection against a partial loss of coolant flow accident is provided by the low primary coolant flow reactor trip signal which is actuated in any reactor coolant loop by two out of three low flow signals. Above Permissive 8, low flow in any loop will actuate a reactor trip. Between approximately 10 percent power (Permissive 7) and the power level corresponding to

Permissive 8, low flow in any two loops will actuate a reactor trip. Above Permissive 7, two or more reactor coolant pump circuit breakers opening will actuate the corresponding undervoltage relays. This results in a reactor trip which serves as a back up to the low flow trip.

15.3.1.2 Analysis of Effects and Consequences

Method of Analysis

This transient (loss of one reactor coolant pump with four loops in operation) is analyzed using two digital computer codes: RETRAN and VIPRE. The RETRAN code (Reference 3) is used to calculate the loop and core flow during the transient, the time of reactor trip based on the calculated flows, the nuclear power transient, and the primary system pressure and temperature transients. The VIPRE code (Reference 4) is then used to calculate the heat flux and DNBR during the transient based on the nuclear power, core inlet enthalpy and flow, and core exit pressure calculated by RETRAN.

Initial Conditions

Initial reactor power, pressurizer pressure, and reactor coolant system (RCS) temperature are assumed to be at their nominal values. Uncertainties in initial conditions are included in the DNBR limit as described in the Revised Thermal Design Procedure (RTDP) (Reference 5). Plant characteristics and initial conditions are further discussed in Section 15.0.3.

Reactivity Coefficients

A conservatively large absolute value of the Doppler coefficient is used. The most positive moderator temperature coefficient is assumed because this results in the maximum core power during the initial part of the transient when the minimum DNBR is reached.

Flow Coastdown

The flow coastdown analysis is based on a momentum balance around each reactor coolant loop and across the reactor core. This momentum balance is combined with the continuity equation, a pump momentum balance and the pump characteristics.

Plant systems and equipment which are available to mitigate the effects of the accident are discussed in Section 15.0.8 and listed in Table 15.0-6. No single active failure in any of these systems or equipment will adversely affect the consequences of this accident.

15.3.1.3 Conclusions

For Units 1 and 2 the analysis shows that the DNBR will not decrease below the limit value at any time during the transient. The DNBR design basis is described in Section 4.4. All applicable acceptance criteria are met.

15.3.2 COMPLETE LOSS OF FORCED REACTOR COOLANT FLOW

15.3.2.1 Identification of Causes and Accident Description

A complete loss of forced reactor coolant flow may result from a simultaneous loss of electrical supplies to all reactor coolant pumps. If the reactor is at power at the time of the accident, the immediate effect of loss of coolant flow is a rapid increase in the coolant temperature. This increase could result in DNB with subsequent fuel damage if the reactor were not tripped promptly.

Normal power for the reactor coolant pumps is supplied through buses from a transformer connected to the generator. When a generator trip occurs, the buses are automatically transferred to a transformer supplied from external power lines, and the pumps will continue to supply coolant flow to the core. Following any automatic turbine trip where there are no electrical or turbine faults which require tripping the generator from the network, the generator remains connected to the network for approximately 30 seconds. The reactor coolant pump buses remain connected to the network, thus ensuring full flow for 30 seconds after the reactor trip before any transfer is made. For a manual turbine trip, or a turbine trip due to certain turbine faults or certain generator protection signals, the generator remains connected to the network for approximately 11.5 seconds. For a complete description of the turbine/generator trip logic, see Figure 7.2-1, Sheet 16 and Figure 10.2-1.

This event is classified as an ANS Condition III incident (an infrequent fault) as defined in Section 15.0.1. However, this transient is analyzed to meet Condition II safety acceptance criteria.

The following signals provide the necessary protection against a complete loss of flow accident:

1. Reactor coolant pump power supply undervoltage or underfrequency.

2. Low reactor coolant loop flow.

The reactor trip on reactor coolant pump undervoltage is provided to protect against conditions which can cause a simultaneous opening of all reactor coolant pump breakers. This function is blocked below approximately 10 percent power (Permissive P-7).

The reactor trip on reactor coolant pump underfrequency is provided to trip the reactor for an underfrequency condition, resulting from frequency disturbances on the power grid. Reference [2] provides analyses of grid frequency disturbances and the resulting Nuclear Steam Supply System protection requirements which are applicable to the Comanche Peak Nuclear Power Plant (CPNPP). The maximum expected frequency decay rate for the Vistra OpCo system power grid is 2.4 Hz./sec. (see Section 8.2.2); thus, the nominal underfrequency setpoint of 57 Hz., as recommended in Reference [2], (which examined grid frequency decay rates as high as 5 Hz./sec.) is appropriate for Comanche Peak.

Due to the rapid decrease in the reactor coolant pump bus frequency following a loss of offsite power, the underfrequency reactor trip function will usually initiate a reactor trip prior to the undervoltage reactor trip function.

The reactor trip on low primary coolant loop flow is provided to protect against loss of flow conditions which affect only one reactor coolant loop. This function is generated by two out of three low flow signals per reactor coolant loop. Above Permissive P-8, low flow in any loop will actuate a reactor trip. Between approximately 10 percent power (Permissive P-7) and the power level corresponding to Permissive P-8, low flow in any two loops will actuate a reactor trip. For a decrease in reactor coolant flow during operation below approximately 10 percent power (Permissive P-7), there is no immediate reactor trip function required. Natural circulation flow in the RCS provides adequate core cooling capability. If the maximum grid frequency decay rate is less than approximately 2.5 Hz./sec., this trip function will protect the core from underfrequency events. This effect is fully described in Reference [2]. In addition, the overtemperature N-16 trip function remains active, and will result in a reactor trip if the core protection limits described in Section 15.0 of the FSAR are approached.

15.3.2.2 Analysis of Effects and Consequences

Method of Analysis

This transient (complete loss of forced reactor coolant flow) is analyzed using two digital computer codes: RETRAN and VIPRE. The RETRAN code (Reference 3) is used to calculate the loop and core flow during the transient, the time of reactor trip based on the calculated flows, the nuclear power transient, and the primary system pressure and temperature transients. The VIPRE code (Reference 4) is then used to calculate the heat flux and DNBR during the transient based on the nuclear power, core inlet enthalpy and flow, and core exit pressure calculated by RETRAN.

The method of analysis and the assumptions made regarding initial operating conditions and reactivity coefficients are similar to those discussed in Section 15.3.1, except that following the loss of power supply to all pumps at power, a reactor trip is actuated by either reactor coolant pump power supply undervoltage or underfrequency.

15.3.2.3 Conclusions

For Units 1 and 2, the analysis performed has demonstrated that for the complete loss of forced reactor coolant flow, the DNBR does not decrease below the limit value at any time during the transient. The design basis for DNBR is described in Section 4.4. All applicable acceptance criteria are met.

15.3.3 REACTOR COOLANT PUMP SHAFT SEIZURE (LOCKED ROTOR)

15.3.3.1 Identification of Causes and Accident Description

The accident postulated is an instantaneous seizure of a reactor coolant pump rotor such as is discussed in Section 5.4. Flow through the affected reactor coolant loop is rapidly reduced, leading to an initiation of a reactor trip on a low flow signal.

Following initiation of the reactor trip, heat stored in the fuel rods continues to be transferred to the coolant causing the coolant to expand. At the same time, heat transfer to the shell side of the steam generators is reduced, first because the reduced flow results in a decreased tube side film coefficient and then because the reactor coolant in the tubes cools down while the shell side temperature increases (turbine steam flow is reduced to zero upon plant trip). The rapid

expansion of the coolant in the reactor core, combined with reduced heat transfer in the steam generators causes an insurge into the pressurizer and a pressure increase throughout the RCS. The insurge into the pressurizer compresses the steam volume, actuates the automatic spray system, opens the power operated relief valves, and opens the pressurizer safety valves, in that sequence. The two power operated relief valves are designed for reliable operation and would be expected to function properly during the accident. However, for conservatism, their pressure reducing effect as well as the pressure reducing effect of the spray is not included in the analysis.

This event is classified as an ANS Condition IV incident (a limiting fault) as defined in Section 15.0.1. This classification is used in the Chapter 15 safety analysis. However, the results of the analysis for this event meet the safety criteria for a Condition III event. The peak RCS pressure is maintained below 110% of the design pressure, and the peak clad average temperature is well below 2700°F.

15.3.3.2 Analysis of Effects and Consequences

Method of Analysis

This transient (locked rotor) is analyzed using two digital computer codes: RETRAN and VIPRE. The RETRAN code (Reference 3) is used to calculate the loop and core flow transients following the pump shaft seizure, the time of reactor trip based on the loop flow transients, the nuclear power transient, and the primary system pressure and temperature transients. The thermal behavior of the fuel located at the core hot spot is analyzed using the VIPRE code (Reference 4), which uses the core flow and the nuclear power calculated by RETRAN. The VIPRE code includes a film boiling heat transfer coefficient.

Two locked rotor cases are analyzed. The first case maximizes the peak clad temperature (PCT) and peak RCS pressure. The second case maximizes the percentage of fuel rods that experience DNB conditions.

At the beginning of the postulated locked rotor accident for the PCT/peak RCS pressure case, i.e., at the time the shaft in one of the reactor coolant pumps is assumed to seize, the plant is assumed to be in operation under the most adverse steady state operating conditions, i.e., maximum guaranteed steady state thermal power, maximum steady state pressure, and maximum steady state coolant average temperature, with consideration for uncertainties in the measurement and control channels. Plant characteristics and initial conditions are further discussed in Section 15.0.3. The accident as evaluated accounts for a loss of offsite power by assuming power to the unaffected reactor coolant pumps is lost coincident with the reactor trip.

For the peak pressure evaluation, a positive moderator temperature coefficient is assumed and the initial pressure is conservatively estimated as 30 pounds per square inch (psi) above nominal pressure (2250 psia) to allow for errors in the pressurizer pressure measurement and control channels.

This is done to obtain the highest possible rise in the coolant pressure during the transient.

For the rods-in-DNB case, the initial core power is assumed to be at the nominal value consistent with steady-state, full-power operation. The initial pressurizer pressure and vessel average temperature are assumed to be at the respective nominal values, and the reactor coolant flow is

at the minimum measured flow value. Uncertainties in the initial conditions are accounted for in the DNBR limit value as described in Reference 5.

Evaluation of the Pressure Transient

After pump seizure, the neutron flux is rapidly reduced by control rod insertion. Rod motion is assumed to begin one second after the flow in the affected loop reaches 87 percent of nominal flow. No credit is taken for the pressure reducing effect of the pressurizer relief valves, pressurizer spray, steam dump or controlled feedwater flow after plant trip.

Although these operations are expected to occur and would result in a lower peak pressure, an additional degree of conservatism is provided by ignoring their effect.

The pressurizer safety valves are fully open at 2575 psia and their capacity for steam relief is as described in Section 5.4. No water relief through the pressurizer safety valves occurs for the reactor coolant pump locked rotor (and shaft break) events.

Evaluation of PCT and Zirconium-Water Reaction During the Accident

For this evaluation, DNB is assumed to occur in the core at the initiation of the transient in order to conservatively predict the peak clad temperature. Therefore, an evaluation of the consequences with respect to fuel rod thermal transients is performed. Results obtained from analysis of this “hot spot” condition represent the upper limit with respect to clad temperature and zirconium-water reaction.

In the evaluation, the rod power at the hot spot is assumed to be 2.5 times the average rod power (i.e., $F_Q = 2.5$) at the initial core power level.

Film Boiling Coefficient

The film boiling coefficient is calculated using the Bishop-Sandberg-Tong film boiling correlation. The fluid properties are evaluated at film temperature (average between wall and bulk temperatures). The program calculates the film coefficient at every time step based upon the actual heat transfer conditions at the time. The neutron flux, system pressure, bulk density and mass flow rate as a function of time are used as program input.

Fuel Clad Gap Coefficient

The magnitude and time dependence of the heat transfer coefficient between fuel and clad (gap coefficient) has a pronounced influence on the thermal results. The larger the value of the gap coefficient, the more heat is transferred between pellet and clad. Based on investigations on the effect of the gap coefficient upon the maximum clad temperature during the transient, the gap coefficient was assumed to increase from a steady state value consistent with the initial fuel temperature to a conservatively large value at the initiation of the transient. Thus the large amount of energy stored in the fuel because of the small initial value is released to the clad at the initiation of the transient.

Zirconium-Steam Reaction

The zirconium-steam reaction can become significant above 1800°F (clad temperature). The Baker-Just parabolic rate equation shown below is used to define the rate of the zirconium-steam reaction.

$$\frac{d(w^2)}{dt} = 33.3 \times 10^6 \exp(-45,500/1.986T)$$

where

w = amount reacted (mg/cm^2)

t = time (sec)

T = temperature (°K)

The heat of reaction is 1510 cal/gm.

The effect of the zirconium-steam reaction is included in the calculation of the “hot spot” clad temperature transient.

Plant systems and equipment which are available to mitigate the effects of the accident are discussed in Section 15.0.8 and listed in Table 15.0-6. No single active failure in any of these systems or equipment will adversely affect the consequences of the accident.

Evaluation of the Radiological Consequences

An evaluation of the number of rods in DNB was performed in order to assess the radiological consequences of this event. Analysis assumptions were made to maximize the heat flux and thus minimize the DNB, consistent with the current FSAR. The number of rods experiencing DNB is determined from a pin census showing the relative peaking factors of each rod.

Locked Rotor

The doses resulting from a locked rotor accident are based on a conservative fission product release to the reactor coolant of the gap activity shown in sheet 2 of Table 15.0-7 from 15% of the fuel rods in the core. The method follows Regulatory Guide 1.195. Prior to the accident, it is assumed that the plant has been operating with simultaneous fuel defects and steam generator tube leakage for a sufficient amount of time to establish equilibrium levels of activity in the primary and secondary coolants equal to the Table 15.1-4 values.

Following the postulated locked rotor accident, the activity released from the pellet-gap due to the fuel failure is assumed to be instantaneously released to the primary coolant and is assumed to be immediately available for release from the RCS.

The following assumptions are used in the analysis:

1. The initial Reactor Coolant System (RCS) iodine activity is 1.0 uCi/gm DE I-131.

2. The initial RCS noble gas activity is based on 1% fuel defects.

3. The initial secondary coolant iodine activity is 0.1 uCi/gm DE I-131.

4. A radial peaking factor ($F_{\Delta H}$) of 1.65 is applied in the calculation of gap activities released (per Regulatory Guide 1.195).

5. 15% of rods are assumed to undergo clad damage sufficient to release all of their gap activity.

6. The primary to secondary leak rate is 1.0 gpm plant total.

A summary of the parameters used in the analysis is given in Table 15.3-1.

Based on the foregoing model, the thyroid and whole body doses are conservatively calculated to be 2.7 rem and 0.17 rem, respectively, for the exclusion area boundary (EAB), and 5.1 rem and 0.058 rem respectively, for the low population zone (LPZ). These doses are well below the values of 30 rem thyroid and 2.5 rem whole body set forth in Regulatory Guide 1.195.

15.3.3.3 Conclusions

For Units 1 and 2, the following conclusions are made:

1. Because the peak RCS pressure reached during any of the transients is less than that which would cause stresses to exceed the faulted condition stress limits, the integrity of the primary coolant system is not endangered.

2. Because the peak clad surface temperature calculated for the hot spot during the worst transient remains considerably less than 2700°F, the core will remain in place and intact with no loss of core cooling capability.

3. The number of rods experiencing DNB remains less than the number of rods assumed to experience DNB for the radiological analysis (i.e., the radiological doses are below the dose values set forth in 10CFR100).

15.3.4 REACTOR COOLANT PUMP SHAFT BREAK

15.3.4.1 Identification of Causes and Accident Description

The accident is postulated as an instantaneous failure of a reactor coolant pump shaft, such as discussed in Section 5.4. Flow through the affected reactor coolant loop is rapidly reduced, though the initial rate of reduction of coolant flow is greater for the reactor coolant pump rotor seizure event. With a failed shaft, the impeller could conceivably be free to spin in the reverse direction instead of being fixed in position. The effect of such reverse spinning is a slight decrease in the end point (steady state) core flow.

The analysis presented in Section 15.3.3 represents the limiting condition, assuming a locked rotor for forward flow but a free-spinning shaft for reverse flow in the affected loop.

15.3.4.2 Conclusions

The conclusions of Section 15.3.3.3 apply for the Reactor Coolant Pump Shaft Break event.

15.4 REACTIVITY AND POWER DISTRIBUTION ANOMALIES

A number of faults have been postulated which could result in reactivity and power distribution anomalies. Reactivity changes could be caused by control rod motion or ejection, boron concentration changes, or addition of cold water to the Reactor Coolant System (RCS). Power distribution changes could be caused by control rod motion, misalignment, or ejection, or by static means such as fuel assembly mislocation. These events are discussed in this section. Detailed analyses are presented for the most limiting of these events.

Discussions of the following incidents are presented in Section 15.4:

1. Uncontrolled rod cluster control assembly bank withdrawal from a subcritical or low power startup condition.

2. Uncontrolled rod cluster control assembly bank withdrawal at power.

3. Rod cluster control assembly misalignment.

4. Startup of an inactive reactor coolant pump at an incorrect temperature.

5. A malfunction or failure of the flow controller in a BWR loop that results in an increased reactor coolant flow rate. (Not applicable to the Comanche Peak Nuclear Power Plant (CPNPP).)

6. Chemical and Volume Control System malfunction that results in a decrease in the boron concentration in the reactor coolant.

7. Inadvertent loading and operation of a fuel assembly in an improper position.

8. Spectrum of rod cluster control assembly ejection accidents.

Items 1, 2, 4, and 6 above are considered to be American Nuclear Society (ANS) Condition II events, item 7 an ANS Condition III event, and item 8 an ANS Condition IV event. Item 3 entails both Condition II and III events. Section 15.0.1 contains a discussion of ANS classifications.

15.4.1 UNCONTROLLED ROD CLUSTER CONTROL ASSEMBLY BANK WITHDRAWAL FROM A SUBCRITICAL OR LOW POWER STARTUP CONDITION

15.4.1.1 Identification of Causes and Accident Description

A rod cluster control assembly (RCCA) withdrawal accident is defined as an uncontrolled addition of reactivity to the reactor core caused by withdrawal of one or more RCCA banks resulting in a power excursion. Such a transient could be caused by operator action or by a malfunction of the reactor control or rod control systems. This could occur with the reactor subcritical, at hot zero power or at power. The “at power” case is discussed in Section 15.4.2.

The RCCA drive mechanisms are wired into preselected bank configurations which are not altered during reactor life. These circuits prevent the RCCAs from being automatically withdrawn in other than their respective banks. Power supplied to the banks is controlled such that no more than two banks can be withdrawn at the same time and in their proper withdrawal sequence. The

RCCA drive mechanisms are of the magnetic latch type and coil actuation is sequenced to provide variable speed travel. The maximum reactivity insertion rate analyzed in the detailed plant analysis is greater than that occurring with the simultaneous withdrawal of the combination of two sequential control banks having the maximum combined worth at maximum speed.

This event is classified as an ANS Condition II incident (a fault of moderate frequency) as defined in Section 15.0.1.

The neutron flux response to a continuous reactivity insertion is characterized by a very fast rise terminated by the reactivity feedback effect of the negative Doppler coefficient. This self limitation of the power excursion is of primary importance since it limits the power to a tolerable level during the delay time for protective action. Should a continuous RCCA withdrawal accident occur, the transient will be terminated by the following automatic features of the Reactor Protection System:

1. Source range high neutron flux reactor trip

   Actuated when either of two independent source range channels indicates a neutron flux level above a preselected manually adjustable setpoint. This trip function may be manually bypassed only after an intermediate range flux channel indicates a flux level above a specified level. It is automatically reinstated when both intermediate range channels indicate a flux level below a specified value.

2. Intermediate range high neutron flux reactor trip

   Actuated when either of two independent intermediate range channels indicates a flux level above a preselected manually adjustable setpoint. This trip function may be manually bypassed only after two out of the four power range channels are reading above approximately 10 percent of full power and is automatically reinstated when three out of the four channels indicate a power level below this value.

3. Power range high neutron flux reactor trip (low setting)

   Actuated when two out of the four power range channels indicate a power level above approximately 25 percent of full power. This trip function may be manually bypassed when two out of the four power range channels indicate a power level above approximately 10 percent of full power and is automatically reinstated only after three out of the four channels indicate a power level below this value.

4. Power range high neutron flux reactor trip (high setting)

   Actuated when two out of the four power range channels indicate a power level above a preset setpoint. This trip function is always active.

5. High nuclear flux rate reactor trip

   Actuated when the positive rate of change of neutron flux on two out of four nuclear power range channels indicates a rate above the preset setpoint. This trip function is always active.

In addition, control rod stops on high intermediate range flux level (one out of two) and high power range flux level (one out of four) serve to discontinue rod withdrawal and prevent the need to actuate the intermediate range flux level trip and the power range flux level trip, respectively.

15.4.1.2 Analysis of Effects and Consequences

Method of Analysis

The analysis of the uncontrolled RCCA bank withdrawal from subcritical accident is performed in three stages. First, a spatial neutron kinetics computer code, TWINKLE (Reference 4), is used to calculate the core average nuclear power transient, including various core feedback effects, i.e., Doppler and moderator reactivity. Next, the FACTRAN computer code (Reference 5) uses the average nuclear power calculated by TWINKLE and performs a fuel rod transient heat transfer calculation to determine the core average heat flux and hot spot fuel temperature transients. Finally, the core average heat flux calculated by FACTRAN is used in the VIPRE computer code (Reference 6) for DNBR calculations.

Plant characteristics and initial conditions are discussed in Section 15.0.3. In order to give conservative results for a startup accident, the following assumptions are made:

1. The magnitude of the power peak reached during the initial part of the transient for any given rate of reactivity insertion is strongly dependent on the Doppler-only power defect. Therefore, a conservatively low absolute value is used to maximize the nuclear power transient.

2. Contribution of the moderator reactivity coefficient is negligible during the initial part of the transient because the heat transfer time between the fuel and the moderator is much longer than the neutron flux response time. However, after the initial neutron flux peak, the succeeding rate of power increase is affected by the moderator reactivity coefficient. The most positive value of the moderator temperature coefficient is used in the analysis to yield the maximum peak heat flux.

3. The reactor is assumed to be at hot zero power. This assumption is more conservative than that of a lower initial system temperature. The higher initial system temperature yields a larger fuel-water heat transfer coefficient, larger specific heats, and a less negative (smaller absolute magnitude) Doppler coefficient, all of which tend to reduce the Doppler feedback effect thereby increasing the neutron flux peak. The initial effective multiplication factor is assumed to be 1.0 since this results in the worst nuclear power transient.

4. Reactor trip is assumed to be initiated by power range high neutron flux (low setting). The most adverse combination of instrument and setpoint errors, as well as delays for trip signal actuation and RCCA release, is taken into account. A 10 percent increase is assumed for the power range flux trip setpoint raising it from the nominal value of 25 percent to 35 percent. Since the rise in the neutron flux is so rapid, the effect of errors in the trip setpoint on the actual time at which the rods are released is negligible. In addition, the reactor trip insertion characteristic is based on the assumption that the highest worth RCCA is stuck in its fully withdrawn position. See Section 15.0.5 for RCCA insertion characteristics.

5. Reactivity insertion rates are assumed to bound the maximum positive reactivity insertion rate that would result from the simultaneous withdrawal of the combination of the two sequential control banks having the greatest combined worth at maximum speed (45 inches/minute). Control rod drive mechanism design is discussed in Section 4.6.

6. The most limiting axial and radial power shapes, associated with having the two highest combined worth banks in their high worth position, are assumed in the DNB analysis.

7. The initial power level was assumed to be below the power level expected for any shutdown condition (10^{-9} of nominal power). The combination of highest reactivity insertion rate and lowest initial power produces the highest peak heat flux.

8. Two reactor coolant pumps are assumed to be in operation.

9. The RCS pressure is below nominal pressure by 30 psi.

Plant systems and equipment which are available to mitigate the effects of the accident are discussed in Section 15.0.8 and listed in Table 15.0-6. No single active failure in any of these systems or equipment will adversely affect the consequences of the accident.

15.4.1.3 Conclusions

For Units 1 and 2, in the event of an RCCA withdrawal accident from the subcritical condition, the core and the RCS are not adversely affected, since the combination of thermal power and the coolant temperature result in a DNBR greater than the limit value. The DNBR design basis as described in Section 4.4; is met.

15.4.2 UNCONTROLLED ROD CLUSTER CONTROL ASSEMBLY BANK WITHDRAWAL AT POWER

15.4.2.1 Identification of Causes and Accident Description

Uncontrolled RCCA bank withdrawal at power results in an increase in the core heat flux. Since the heat extraction from the steam generator lags behind the core power generation until the steam generator pressure reaches the relief or safety valve setpoint, there is a net increase in the reactor coolant temperature. Unless terminated by manual or automatic action, the power mismatch and resultant coolant temperature rise could eventually result in DNB.

Therefore, in order to avert damage to the fuel clad the Reactor Protection System is designed to terminate any such transient before the DNBR falls below the limit value.

This event is classified as an ANS Condition II incident (a fault of moderate frequency) as defined in Section 15.0.1.

The automatic features of the Reactor Protection System which prevent core damage following the postulated accident include the following:

1. Power range neutron flux instrumentation actuates a reactor trip if two out of four channels exceed an overpower setpoint.

2. Reactor trip is actuated if any two out of four N-16 channels exceed an Overtemperature N-16 setpoint. This setpoint is automatically varied with axial power imbalance, coolant temperature and pressure to protect against DNB.

3. Reactor trip is actuated if any two out of four N-16 channels exceed an Overpower N-16 setpoint. This setpoint can be automatically varied with axial power imbalance to ensure that the allowable heat generation rate (kW/ft) is not exceeded.

4. A high pressurizer pressure reactor trip actuated from any two out of four pressure channels, which is set at a fixed point. This set pressure is less than the set pressure for the pressurizer safety valves.

5. A high pressurizer water level reactor trip actuated from any two out of three level channels when the reactor power is above approximately 10 percent (Permissive-7).

6. Reactor trip is actuated if any two of four power range neutron flux high positive rate channels exceed a setpoint to protect against exceeding the Reactor Coolant System pressure limits.

In addition to the above listed reactor trips, there are the following RCCA withdrawal blocks:

1. High neutron flux (one out of four power range).

2. Overpower N-16 (two out of four).

3. Overtemperature N-16 (two out of four).

The manner in which the combination of Overpower and Overtemperature N-16 trips provide protection over the full range of RCS conditions is described in Chapter 7. Figure 15.0-1 presents allowable reactor coolant loop T_{cold} and power for the design power distribution and flow as a function of primary coolant pressure. The boundaries of operation defined by the Overpower N-16 trip and the Overtemperature N-16 trip are represented as “protection lines” on this diagram. The utility of this diagram is in the fact that the limit imposed by any given DNBR can be represented as a line. The DNB lines represent the locus of conditions for which the DNBR equals the limit value. All points below and to the left of a DNB line for a given pressure have a DNBR greater than the limit value. The diagram shows that DNB is prevented for all cases if the area enclosed with the maximum protection lines is not traversed by the applicable DNBR line at any point.

The area of permissible operation (power, pressure and temperature) is bounded by the combination of reactor trips: high neutron flux (fixed setpoint); high pressure (fixed setpoint); low pressure (fixed setpoint); Overpower and Overtemperature N-16 (variable setpoints).

15.4.2.2 Analysis of Effects and Consequences

Method of Analysis

This transient is analyzed for Units 1 and 2 using the RETRAN computer code (Reference 10).

Multiple cases (with varying reactivity insertion rates) at initial power levels of 100%, 60% and 10% of rated thermal were analyzed.

Plant characteristics and initial conditions are discussed in Section 15.0.3. In order to obtain conservative results for an uncontrolled rod withdrawal at power accident, the following assumptions are made:

1. The initial core power, pressurizer pressure and vessel average temperature are assumed to be at the respective nominal values, and the reactor coolant flow is at the minimum measured flow value. Uncertainties in the initial conditions are accounted for in the DNBR limit value as described in Reference 11.

2. Reactivity coefficients - two feedback conditions are analyzed:

   a. Minimum reactivity feedback

      A least negative or positive value of the moderator temperature coefficient of reactivity is assumed corresponding to the beginning of core life. A conservatively small (in absolute magnitude) value of the Doppler coefficient is assumed.

   b. Maximum reactivity feedback

      A conservatively large positive moderator density coefficient and a large (in absolute magnitude) negative Doppler coefficient are assumed.

3. The reactor trip on high neutron flux is assumed to be actuated at a conservative value of 115 percent of nominal full power. The N-16 trips include allowances for all adverse instrumentation and setpoint errors; the delays for trip actuation are assumed to be the maximum values.

4. The RCCA trip insertion characteristic is based on the assumption that the highest worth assembly is stuck in its fully withdrawn position.

5. The maximum positive reactivity insertion rate is greater than that for the simultaneous withdrawal of the combinations of the two control banks having the maximum combined worth at maximum speed.

The effect of RCCA movement on the axial core power distribution is accounted for by causing a decrease in Overtemperature N-16 trip setpoint proportional to a decrease in margin to DNB. For conservatism, this feature is not credited in the analysis of the uncontrolled RCCA bank withdrawal at power event.

Plant systems and equipment which are available to mitigate the effects of the accident are discussed in Section 15.0.8 and listed in Table 15.0-6. No single active failure in any of these systems or equipment will adversely affect the consequences of the accident.

15.4.2.3 Conclusions

For Units 1 and 2, all relevant event acceptance criteria are satisfied. The reactor is tripped sufficiently fast during the RCCA withdrawal at power transient to ensure that the ability of the

primary coolant to remove heat from the fuel rods is not reduced. Thus, the fuel cladding temperature does not rise significantly above its initial value during the transient.

The high neutron flux, Overtemperature N-16 and Overpower N-16 trip channels provide adequate protection over the entire range of possible reactivity insertion rates; i.e., the minimum value of DNBR is always larger than the limit value.

15.4.3 ROD CLUSTER CONTROL ASSEMBLY MISALIGNMENT (SYSTEM MALFUNCTION OR OPERATOR ERROR)

15.4.3.1 Identification of Causes and Accident Description

Rod cluster control assembly (RCCA) misoperation accidents include:

1. One or more dropped RCCAs within the same group,

2. A dropped RCCA bank,

3. Statically misaligned RCCA,

4. Withdrawal of a single RCCA.

Each RCCA has a position indicator channel which displays the position of the assembly. The displays of assembly positions are grouped for the operator's convenience. Fully inserted assemblies are further indicated by a rod at bottom signal, which actuates an alarm and a control room annunciator. Group demand position is also indicated.

Full length RCCAs are moved in preselected banks, and the banks are moved in the same preselected sequence. Each control bank of RCCAs is divided into two groups. The rods comprising a group operate in parallel through multiplexing thyristors. The two groups in a bank move sequentially such that the first group is always within one step of the second group in the bank. A definite schedule of actuation (or deactuation of the stationary gripper, movable gripper, and lift coils of a mechanism) is required to withdraw the RCCA attached to the mechanism. Since the stationary gripper, movable gripper, and lift coils associated with the four RCCAs of a rod group are driven in parallel, any single failure which would cause rod withdrawal would affect a minimum of one group. Mechanical failures are in the direction of insertion, or immobility.

The dropped RCCA assemblies, dropped RCCA assembly bank, and statically misaligned RCCA assembly events are classified as ANS Condition II incidents (incidents of moderate frequency) as defined in Section 15.0.1. The single RCCA withdrawal incident is classified as an ANS Condition III event (i.e., an infrequent fault), as discussed below.

No single electrical or mechanical failure in the rod control system could cause the accidental withdrawal of a single RCCA from the inserted bank at full power operation. The operator could withdraw a single RCCA in the control bank since this feature is necessary in order to retrieve an assembly should one be accidentally dropped. The event analyzed must result from multiple wiring failures (probability for single random failure is of the order of 10^{-4}/year; refer to Section 7.7.2.2) or multiple significant operator errors and subsequent and repeated operator

disregard of event indication. The probability of such a combination of conditions is considered sufficiently low that the limiting consequences may include slight fuel damage.

Thus, consistent with the philosophy and format of ANSI N18.2, the event is classified as a Condition III event. By definition “Condition III occurrences include incidents, any one of which may occur during the lifetime of a particular plant”, and “shall not cause more than a small fraction of fuel elements in the reactor to be damaged...”

The selection of this criterion is in accordance with GDC 25 which states, “The protection system shall be designed to assure that specified acceptable fuel design limits are not exceeded for any single malfunction of the reactivity control systems, such as accidental withdrawal (not ejection or dropout) of control rods.” (Emphases have been added). It has been shown that single failures resulting in RCCA bank withdrawals do not violate specified fuel design limits. Moreover, no single malfunction can result in the withdrawal of a single RCCA. Thus, it is concluded that the criterion established for the single rod withdrawal at power accident is appropriate and in accordance with GDC 25.

A dropped RCCA or RCCA bank is detected by:

1. Sudden drop in the core power level as seen by the Nuclear Instrumentation System,

2. Asymmetric power distribution as seen on out-of-core neutron detectors or core exit thermocouples,

3. Rod at bottom signal,

4. Rod deviation alarm, or

5. Rod position indication.

Misaligned RCCAs are detected by:

1. Asymmetric power distribution as seen on out-of-core neutron detectors or core exit thermocouples,

2. Rod deviation alarm, or

3. Rod position indicators.

Rod position is displayed in 6 step increments with an accuracy of ±4 steps. Deviation of any RCCA from its group by twice this distance (12 steps) will not cause power distributions worse than the design limits. The deviation alarm alerts the operator to rod deviation with respect to the group position in excess of 6 steps. If the rod deviation alarm is not operable, the operator is required to take action as required by the Technical Requirements Manual (TRM).

If one or more rod position indicator channels should be out of service, detailed operating instructions shall be followed to assure the alignment of the non-indicated RCCAs. The operator is also required to take action as required by the technical specifications.

In the extremely unlikely event of simultaneous electrical failures which could result in single RCCA withdrawal, rod deviation and rod control urgent failure would both be displayed on the plant annunciator, and the rod position indicators would indicate the relative positions of the assemblies in the bank. The urgent failure alarm also inhibits automatic rod motion in the group in which it occurs. Withdrawal of a single RCCA by operator action, whether deliberate or by a combination of errors, would result in activation of the same alarm and the same visual indications. Withdrawal of a single RCCA results in both positive reactivity insertion tending to increase core power, and an increase in local power density in the core area associated with the RCCA. Automatic protection for this event is provided by the Overtemperature N-16 reactor trip, although due to the increase in local power density it is not possible in all cases to provide assurance that the core safety limits will not be violated.

Plant systems and equipment which are available to mitigate the effects of the various control rod misoperations are discussed in Section 15.0.8 and listed in Table 15.0-6. No single active failure in any of these systems or equipment will adversely affect the consequences of the accident.

15.4.3.2 Analysis of Effects and Consequences

1. Dropped RCCAs, dropped RCCA bank, and statically misaligned RCCA.

   Method of Analysis

   a. One or more dropped RCCAs from the same group.

      For evaluation of the dropped RCCA event, the transient system response is calculated using the LOFTRAN computer code (Reference 7) with the methodology described in Reference 8.

      Statepoints are calculated and nuclear models are used to obtain a hot channel factor consistent with the primary system conditions and reactor power. By incorporating the primary conditions from the transients and the hot channel factor from the nuclear analysis, the DNB basis can be shown to be met using dropped rod limit lines developed with the VIPRE computer code (Reference 6).

      Single or multiple dropped RCCAs within the same group result in a negative reactivity insertion. If the worth of the dropped rod(s) is sufficiently large, and if the turbine load is constant, a reactor trip may occur on low pressurizer pressure due to the mismatch between the reactor power and the turbine power. The core is not adversely affected during this period since power is decreasing rapidly. Following reactor trip, normal shutdown procedures are followed. The operator may manually retrieve the RCCA by following approved operating procedures.

      For those dropped RCCAs which do not result in a reactor trip, power may be reestablished either by reactivity feedback or control bank withdrawal. Following a dropped rod event in manual rod control, the plant will establish a new equilibrium condition. The equilibrium process without control system interaction is monotonic, thus removing power overshoot as a concern, and establishing the automatic rod control mode of operation as the limiting case.

For a dropped RCCA event in the automatic rod control mode, the Rod Control System detects the drop in power and initiates control bank withdrawal. Power overshoot may occur due to this action by the automatic rod controller after which the control system will insert the control bank to restore nominal power. Uncertainties in the initial conditions are included in the DNB evaluation. In all cases, the minimum DNBR remains above the limit value.

b. Dropped RCCA Bank

A dropped RCCA bank typically results in a negative reactivity insertion greater than 500 pcm. Due to the relatively large worth of the dropped bank, and if the turbine load is constant, a reactor trip may occur on low pressurizer pressure due to the mismatch between the reactor power and the turbine power. The core is not adversely affected during this period, since power is decreasing rapidly. Following reactor trip, normal shutdown procedures are followed to further cool down the plant. Any action required of the operator to maintain the plant in a stabilized condition will be in a time frame in excess of ten minutes following the incident.

c. Statically Misaligned RCCA

No transient analysis is performed, rather steady state power distributions are analyzed using the ANC computer code (Reference 9 and beginning with Unit 2 Cycle 19 and Unit 1 Cycle 22, Reference 9 and Reference 12). The peaking factors are then compared to peaking factor limits developed using the VIPRE computer code (Reference 6), which are based on meeting the DNB design criterion.

The most severe misalignment situations with respect to DNBR at significant power levels arise from cases in which one RCCA is fully inserted, or where bank D is fully inserted with one RCCA fully withdrawn. Multiple independent alarms, including a bank insertion limit alarm, alert the operator well before the postulated conditions are approached. The bank can be inserted to its insertion limit with any one assembly fully withdrawn without the DNBR falling below the limit value.

The insertion limits in the technical specifications may vary from time to time depending on a number of limiting criteria. It is preferable, therefore, to analyze the misaligned RCCA case at full power for a position of the control bank as deeply inserted as the criteria on minimum DNBR and power peaking factor will allow. The full power insertion limits on control bank D must then be chosen to be above that position and will usually be dictated by other criteria. Detailed results will vary from cycle to cycle depending on fuel arrangements.

For this RCCA misalignment, with bank D inserted to its full power insertion limit and one RCCA fully withdrawn, DNBR does not fall below the limit value. This case is analyzed assuming the initial reactor power, and RCS pressure and temperature are at their nominal values including uncertainties but with the increased radial peaking factor associated with the misaligned RCCA.

DNB calculations have not been performed specifically for RCCAs missing from other banks; however, power shape calculations have been done as required for the RCCA ejection analysis. Inspection of the power shapes shows that the DNB and peak kw/ft situation is less severe than the bank D case discussed above assuming insertion limits on the other banks equivalent to a bank D full-in insertion limit.

For RCCA misalignments with one RCCA fully inserted, the DNBR does not fall below the limit value. This case is analyzed assuming the initial reactor power, and RCS pressure and temperature are at their nominal values, including uncertainties but with the increased radial peaking factor associated with the misaligned RCCA.

DNB does not occur for the RCCA misalignment incident and thus the ability of the primary coolant to remove heat from the fuel rod is not reduced. The peak fuel temperature corresponds to a linear heat generation rate based on the radial peaking factor penalty associated with the misaligned RCCA and the design axial power distribution. The resulting linear heat generation is well below that which would cause fuel melting.

Following the identification of a RCCA group misalignment condition by the operator is required to take action as required by the plant technical specifications and operating instructions.

2. Single RCCA Withdrawal

Method of Analysis

Power distributions within the core are calculated using the ANC computer code (Reference 9 and beginning with Unit 2 Cycle 19 and Unit 1 Cycle 22, Reference 9 and Reference 12). The peaking factors are then used by the VIPRE computer code (Reference 6) to calculate the DNBR for the event. The case of the worst rod withdrawn from bank D inserted at the insertion limit, with the reactor initially at full power, is analyzed. This incident is assumed to occur at the initial core power, pressurizer pressure and vessel average temperature are assumed to be at the respective nominal values, and the reactor coolant flow is at the minimum measured flow value. Uncertainties in the initial conditions are accounted for in the DNBR limit value as described in Reference 11.

For the single rod withdrawal event, two cases are considered as follows:

a. If the reactor is in the manual control mode, continuous withdrawal of a single RCCA results in both an increase in core power and coolant temperature, and an increase in the local hot channel factor in the area of the withdrawing RCCA. In terms of the overall system response, this case is similar to those presented in Section 15.4.2; however, the increased local power peaking in the area of the withdrawn RCCA results in lower minimum DNBRs than for the withdrawn bank cases. Depending on initial bank insertion and location of the withdrawn RCCA, automatic reactor trip may not occur sufficiently fast to prevent the minimum DNBR from falling below the limit value. Evaluation of this case at the power and

coolant conditions at which the Overtemperature N-16 trip would be expected to trip the plant shows that an upper limit for the number of fuel rods with a DNBR less than the limit value is 5 percent of the total rods in the core.

b. If the reactor is in the automatic control mode, the multiple failures that result in the withdrawal of a single RCCA will result in the immobility of the other RCCAs in the controlling bank. The transient will then proceed in the same manner as Case a described above.

For such cases as above, a reactor trip will ultimately ensue, although not sufficiently fast in all cases to prevent a minimum DNBR in the core of less than the limit value. Following reactor trip, normal shutdown procedures are followed. No single failure of the Reactor Trip System will negate the protection functions required for the single RCCA withdrawal accident, or adversely affect the consequences of the accident.

15.4.3.3 Conclusions

For Units 1 and 2, it is confirmed that the DNBR remains greater than the limit value for all cases of dropped RCCAs and dropped banks; therefore the DNB design basis is met. It is shown for all cases which do not result in reactor trip that the DNBR remains greater than the limit value and, therefore, the DNB design is met.

For all cases of any RCCA fully inserted, or bank D inserted to its rod insertion limits with any single RCCA in that bank fully withdrawn (static misalignment), the DNBR remains greater than the limit value.

For the case of the accidental withdrawal of a single RCCA, with the reactor in the automatic or manual control mode and initially operating at full power with bank D at the insertion limit, an upper bound of the number of fuel rods experiencing DNB is 5 percent of the total fuel rods in the core.

15.4.4 STARTUP OF AN INACTIVE REACTOR COOLANT PUMP AT AN INCORRECT TEMPERATURE

15.4.4.1 Identification of Causes and Accident Description

If the plant is operating with one pump out of service, there is reverse flow through the inactive loop due to the pressure difference across the reactor vessel. The cold leg temperature in an inactive loop is identical to the cold leg temperature of the active loops (the reactor core inlet temperature). If the reactor is operated at power, and assuming the secondary side of the steam generator in the inactive loop is not isolated, there is a temperature drop across the steam generator in the inactive loop and, with the reverse flow, the hot leg temperature of the inactive loop is lower than the reactor core inlet temperature.

CPNPP technical specifications require all four reactor coolant loops to be in operation while at power or in startup conditions (Modes 1 and 2). Since by definition, the event can only occur during power operations (Mode 1 and 2) when a loop is out of service, a detailed analysis of this event is not presented.

15.4.5 A MALFUNCTION OR FAILURE OF THE FLOW CONTROLLER IN A BWR LOOP THAT RESULTS IN AN INCREASED REACTOR COOLANT FLOW RATE

This section is not applicable to the CPNPP.

15.4.6 CHEMICAL AND VOLUME CONTROL SYSTEM MALFUNCTION THAT RESULTS IN A DECREASE IN THE BORON CONCENTRATION IN THE REACTOR COOLANT

15.4.6.1 Identification of Causes and Accident Description

One of the two principal means of positive reactivity insertion to the core is the addition of unborated, primary grade water from the Demineralized and Reactor Makeup Water System (RMWS) into the RCS through the reactor makeup portion of the Chemical and Volume Control System (CVCS). Boron dilution with these systems is a manually initiated operation under strict administrative controls requiring close operator surveillance with procedures limiting the rate and duration of the dilution. A boric acid blend system is available to allow the operator to match the makeup's boron concentration to that of the RCS during normal charging.

A comprehensive review of the primary system showed that a single failure in the NaOH spray system would not result in a boron dilution of the Reactor Coolant System and that the CVCS malfunction represents the most limiting potential source of dilution. Based on this review, it is clear that the analysis results presented below bounds all potential sources of inadvertent dilution under all modes of operation.

The principal means of causing an inadvertent boron dilution are the opening of the primary water makeup control valve and failure of the blend system, either by controller or mechanical failure. The CVCS and RMWS are designed to limit, even under various postulated failure modes, the potential rate of dilution to values which, with indication by alarms and instrumentation, will allow sufficient time for automatic or operator response (depending on the mode of operation) to terminate the dilution. An inadvertent dilution from the RMWS may be terminated by closing the primary water makeup control valve. All expected sources of dilution may be terminated by closing isolation valves in the CVCS, 1,2-LCV-112B and C. The lost shutdown margin (SDM) may be regained by the opening of isolation valves to the RWST, 1,2-LCV-112D and E, thus allowing the addition of borated water to the RCS.

The rate at which unborated water can be added to the RCS is limited by the design of the CVCS and RMWS. Alarms in the CVCS are available to alert the reactor operators to high flow rates. In addition, the makeup flow is limited to a maximum dilution flow rate of 167 gpm for Cold Shutdown, Hot Shutdown and Hot Standby.

Generally, to dilute, the operator must perform two distinct actions:

1. Switch control of the makeup from the automatic makeup mode to the dilute mode, and

2. Turn the RCS makeup actuation handswitch to the "on" position.

Failure to carry out either of the above actions prevents initiation of dilution. Also during normal operation the operator may add borated water to the RCS by blending boric acid from the boric acid storage tanks with primary grade water. This requires the operator to determine the

concentration of the addition and to set the blended flow rate and the boric acid flow rate. The makeup controller will then limit the sum of the boric acid flow rate and primary grade water flow rate to the blended flow rate after turning the RCS system makeup actuation switch to the “on” position (i.e., the controller determines the primary grade water flow rate).

The status of the RCS makeup is continuously available to the operator by:

1. Indication of the boric acid and blended flow rates,

2. CVCS and RMWS pump status lights,

3. Deviation alarms if the boric acid or blended flow rates deviate by ± 1 gpm or ± 8 gpm, respectively, from the preset values,

4. High charging flow rate alarm,

5. Volume control tank high and high-high water level and high pressure alarms,

6. Letdown divert valve position alarm,

7. Source Range Neutron Flux - when reactor is subcritical;

    a. High Flux at Shutdown Alarm,

    b. Indicated Source Range Neutron Flux count rates,

    c. Audible Source Range Neutron Flux count rate, and

    d. Source Range Neutron Flux - Doubling Alarm.

8. With the reactor critical

    a. Axial Flux Difference Alarm (reactor power ≥ 50% RTP),

    b. Control Rod Insertion Limit Low and Low-Low Alarms,

    c. Overtemperature N-16 Alarm (at power),

    d. Overtemperature N-16 turbine runback (at power),

    e. Overtemperature N-16 Reactor Trip, and

    f. Power Range Neutron Flux - High, both high and low setpoint Reactor Trips.

This event is classified as an ANS Condition II incident (a fault of moderate frequency) as defined in Section 15.0.1.

15.4.6.2 Analysis of Effects and Consequences

To cover all phases of plant operation, boron dilution during Refueling, Cold Shutdown, Hot Shutdown, Hot Standby, Startup, and Power modes of operation are considered in this analysis. Conservative values for necessary parameters were used, i.e., high RCS critical boron concentrations, high boron worths, minimum shutdown margins, and lower than actual RCS volumes. These assumptions result in conservative determinations of the time available for operator or system response after detection of a dilution transient in progress.

Dilution During Refueling

An uncontrolled boron dilution transient cannot occur during this mode of operation. Inadvertent dilution is prevented by administrative controls which isolate the RCS from the potential source of unborated water. Either valve 1,2CS-8455 or valves 1,2CS-8560, 1,2FCV-111B, 1,2CS-8441, 1,2CS-8453 and 1,2CS-8439 in the CVCS will be locked closed during refueling operations. These valves block all flow paths that could allow significant rates of unborated makeup water to reach the RCS. Any makeup which is required during refueling will be borated water supplied from the RWST.

Dilution During Cold Shutdown, Hot Shutdown and Hot Standby

The Technical Specifications require the reactor to be shutdown by the amount specified in the Core Operating Limits Report when the unit is operating in Mode 5 (Cold Shutdown), Mode 4, or 3, (Hot Shutdown or Hot Standby). The following conditions are assumed for the analysis of the inadvertent boron dilution event while in these operating modes:

1. An assumed dilution flow rate of 157.5 gpm is used. This value corresponds to the high charging flow rate alarm plus a 5% allowance for uncertainties.

2. The following minimum RCS water volumes are used while in these operating modes:

Mode(s)	RCS Water Volume (ft^3)	Assumption Used to Minimize RCS Water Volume
3, 4, & 5 (filled)	9903.7 (Unit 1) 8594.1 (Unit 2)	The volumes for the pressurizer, surge line and reactor vessel upper head were excluded.
5 (drained)	4513.0 (Units 1 & 2)	The RCS water level is drained down to the mid-plane of the hot legs.

3. If no reactor coolant pump is in operation, all dilution sources are isolated or under administrative control.

Dilution During Startup

Startup is a transitory mode of operation. In this mode the plant is being taken from one long term mode of operation, Hot Standby, to another, Power. The plant is maintained in the Startup mode only for the purpose of startup testing at the beginning of each cycle. During this mode of operation the plant is in manual control, i.e., T_{avg}/ rod control is in manual. All normal actions required to change power level, either up or down, require operator initiation. The Technical

Specifications require a SDM of at least 1.3% ΔK/K and four reactor coolant pumps operating. Other conditions assumed are:

1. Dilution flow rate is limited by the design of the CVCS and RMWS. The makeup flow rate is limited to a maximum of 157.5 gpm for startup, which corresponds to the high charging flow alarm plus uncertainties.

2. A minimum RCS water volume of 11072 (Unit 1) and 9762 (Unit 2) ft^3. These very conservative estimates of the active RCS volume exclude the pressurizer and surge line volumes.

Dilution During Full Power Operation

The plant may be operated at power two ways, automatic T_{avg}/rod control or under manual (operator) rod control. The Technical Specifications require an available shutdown margin as specified in the Core Operating Limits Report and four reactor coolant pumps operating. With the plant at power and the RCS at pressure, the dilution rate is limited by the capacity of the centrifugal charging pumps (analysis is performed assuming two charging pumps are in operation even though normal operation is with one pump). Conditions assumed for this mode are:

1. Dilution flow rate is limited by the design of the CVCS and RMWS. The makeup flow rate is limited to a maximum of 157.5 gpm, which corresponds to the high charging flow alarm plus uncertainties. When the pressurizer level control is in manual, the maximum assumed dilution flow rate is 157.5 gpm and when in automatic pressurizer level control, the dilution is limited to the maximum letdown flow rate (approximately 125 gpm).

2. A minimum RCS water volume of 11072 (Unit 1) and 9762 (Unit 2) ft^3. These very conservative estimates of the active RCS volume exclude the pressurizer and surge line volumes.

15.4.6.3 Conclusions

Dilution During Refueling

Dilution during this mode has been precluded through administrative control of valves in the possible dilution flow paths (see Section 15.4.6.2).

Dilution During Cold Shutdown, Hot Shutdown, or Hot Standby

In Modes 3, 4, or 5, the reactor operators are relied upon to detect and recover from an inadvertent boron dilution event. Numerous alarms from the CVCS and RMWS and in the Nuclear Instrumentation System are available to provide assistance to the reactor operator in the detection of an inadvertent boron dilution event. In the analyses of the event initiated from Mode 3, 4, or 5, the VCT high water level alarm (at 70% span) is credited as the initial alarm. The time required to perform the VCT/RWST valve swap-over and to purge the charging lines of dilute water are included in the calculation of the time available to the reactor operators to initiate corrective actions. For both units, in Modes 3, 4 and 5, analyses have demonstrated that the

reactor operators have at least 15 minutes in which to initiate actions to terminate the dilution and initiate boration of the RCS.

Dilution During Startup

This mode of operation is a transitory mode to go to power and is the operational mode in which the operator intentionally dilutes and withdraws control rods to take the plant critical. During this mode the reactor is in manual rod control with the operator required to maintain a very high awareness of the plant status. For a normal approach to criticality the operator must manually initiate a limited dilution and subsequently manually withdraw the control rods, a process that takes several hours. The plant Technical Specifications require that the operator determine the estimated critical position of the control rods prior to approaching criticality thus assuring that the reactor does not go critical with the control rods below the insertion limits. Once critical, the power escalation must be sufficiently slow to allow the operator to manually block the Source Range reactor trip after receiving P-6 from the Intermediate Range. Too fast a power escalation (due to an unknown dilution) would result in reaching P-6 unexpectedly, leaving insufficient time to manually block the Source Range reactor trip. Failure to perform this manual action results in a reactor trip and immediate shutdown of the reactor.

However, in the event of an unplanned approach to criticality or dilution during power escalation while in the Startup mode, the plant status is such that minimal impact will result. The plant will slowly escalate in power to a reactor trip on the Power Range Neutron Flux - High, low setpoint (nominally 25% RTP). After reactor trip there is at least 15 minutes for operator action prior to return to criticality. The required operator action is the opening of valves 1,2-LCV-112D and E to initiate boration and the closing of valves 1,2-LCV-112B and C to terminate dilution.

Dilution During Full Power Operation

With the reactor under manual rod control and no operator action taken to terminate the transient, the power and temperature rise will cause the reactor to reach the Overtemperature N-16 trip setpoint resulting in a reactor trip. After reactor trip there is at least 15 minutes for operator action prior to return to criticality. The required operator action is the opening of valves 1,2-LCV-112D and E and the closing of valves 1,2-LCV-112B and C. The boron dilution transient in this case is essentially equivalent to an uncontrolled rod withdrawal at power. A reactor trip occurs when either the Hi Neutron Flux or the Overtemperature N-16 setpoint is reached. The maximum reactivity insertion rate for a boron dilution transient is conservatively estimated to be within the range of insertion rates analyzed for uncontrolled rod withdrawal at power.

It should be noted that prior to reaching the Overtemperature N-16 reactor trip the operator will have received an alarm on Overtemperature N-16 and an Overtemperature N-16 turbine runback. With the reactor in automatic rod control the pressurizer level controller will limit the dilution flow rate to the maximum letdown rate, approximately 125 gpm. If a dilution rate in excess of the letdown rate is present, the pressurizer level controller will throttle charging flow down to match the letdown rate.

Thus, with the reactor in automatic rod control, a boron dilution will result in a power and temperature increase such that the rod controller will attempt to compensate by slow insertion of the control rods. This action by the controller will result in at least three alarms to the operator:

1. rod insertion limit - low level alarm,

2. rod insertion limit - low-low level alarm if insertion continued after (1) above, and

3. axial flux difference alarm (ΔI outside of the target band).

Given the many alarms, indications, and the inherent slow process of dilution at power, the operator has sufficient time for action. For example, the operator has at least 15 minutes from the rod insertion limit low-low alarm until the shutdown margin is completely eroded at beginning-of-life. The time would be significantly longer at end-of-life, due to the low initial boron concentration, when shutdown margin is a concern.

The above results demonstrate that in all modes of operation an inadvertent boron dilution is precluded, or sufficient time is available for operator action to terminate the transient. Following termination of the dilution flow and initiation of boration, the reactor is in a stable condition with the operator regaining the required shutdown margin.

15.4.7 INADVERTENT LOADING AND OPERATION OF A FUEL ASSEMBLY INTO AN IMPROPER POSITION

15.4.7.1 Acceptance Criteria

This event is classified as a Condition III event. Condition III events are defined as those events that do not cause more than a small fraction of fuel rods to fail, although sufficient fuel damage might occur to preclude immediate resumption of operation. The specific acceptance criteria for this even are as follows:

a. To meet the requirements of General Design Criteria 13, plant operating procedures should include a provision requiring that reactor instrumentation be used to search for potential fuel loading errors after fueling operations.

b. In the event the error is not detectable by the instrumentation system and fuel rod failure limits could be exceeded during normal operation, the offsite consequences should be a small fraction of the 10 CFR Part 100 guidelines.

15.4.7.2 Identification of Causes and Accident Description

The Inadvertent Loading Event comprises core misloading scenarios such as the loading of one or more fuel assemblies into improper positions, the loading of a fuel rod during manufacture with one or more pellets of the wrong enrichment, or the loading of a full fuel assembly during manufacture with pellets of the wrong enrichment. In addition to these scenarios, misloading events involving burnable absorbers are theoretically possible, scenarios such as the placement of a cluster of 20 burnable absorbers into a core location slated to have 24 burnable absorbers. All of these misloading scenarios potentially result in a core reactivity distribution that differs from the intended core reactivity distribution. As a result, the core power distribution and peaking factors may differ from predictions. Specifically, misloading errors can lead to increased local power peaking at the location of the misloading if the misloading results in a local reactivity increase relative to the intended pattern. If the misloading results in a local reactivity decrease, power peaking increases away from the location of the misloading are possible due to

unintended power tilts. These kinds of increases, however, are generally distributed over a large core volume and are small relative to those where the local reactivity is increased.

Fuel misloads are prevented by the manufacturing controls employed to build the fuel and the core loading controls used to assemble the core. The manufacturing controls include checks on fuel rod weight to confirm the uranium loading in the fuel rod, active and passive gamma scans of individual fuel rods to confirm fuel enrichments, pellet stack lengths, pellet types, and the absence of pellet gaps during fuel manufacturing, and bar coding of each fuel rod to confirm its proper placement in the fuel assembly.

To reduce the probability of core loading errors during fuel loading, each fuel assembly and core component is marked with an identification number and loaded in accordance with a core loading diagram. During core loading, the fuel identification numbers are checked before each assembly is moved into the core. Identification numbers read during fuel movement are subsequently recorded on the loading diagram as a further check on proper placement after the loading is completed. The correct type of insert is also confirmed for each location. These procedures make the likelihood of core misloadings very small.

The severity and detectability of fuel misloads are influenced by several factors: the local reactivity perturbation relative to the intended core loading pattern, the core position of the misload, the local environment of the misloaded fuel assembly, and the number of operable incore detector locations and their proximity to the misload location. Should misloadings occur, the incore system of movable flux detectors, which is used to verify power distributions during startup and throughout the operating cycle, is capable of revealing enrichment errors or misloadings which would cause the kind of substantial power distribution perturbation that would be necessary to induce large numbers of fuel rod failures. In addition, thermocouples and excore detectors can provide additional indications of power distribution anomalies. This instrumentation, along with the startup testing performed each cycle, make the detection of severe misloadings highly likely.

15.4.7.3 Evaluation

The incore moveable detector system is used to search for potential fuel misloads at the start of each operating cycle. Following fuel loading and low power physics testing, an initial core power distribution measurement is made. The core power level of this initial flux map is typically between ~30% and ~50% of rated thermal power. This initial power distribution measurement is used to confirm that the measured power distribution is consistent with the predicted power distribution. Observed flux map deviations in excess of the flux map review criteria (see Table 1) would prompt an investigation of a possible core anomaly. This satisfies the first acceptance criterion given above.

In Reference 1, a large number of misloads were evaluated for representative core designs employing current fuel types and fuel features. The simulated misloads, involving one or two fuel assemblies, covered a wide range of local reactivity perturbations and core positions. The resulting hot full power (HFP) $F\Delta H$ peaking factors ranged from benign to very severe. Severe misloads with peaking factors that exceed the $F\Delta H$ limit for DNB at normal operation conditions have the potential for fuel failure if they remain undetected. The simulated misloads were assessed with respect to severity and detectability.

The detectability assessments of Reference 1 demonstrated that the incore detector system is very robust with respect to detection of misloads severe enough to fail fuel during normal operation. By examining a large number of moveable detector thimble patterns, the detectability assessments considered the effect of inoperable moveable detector thimbles on misload detectability. Even when the minimum number of operable detector locations allowed per the plant licensing bases was assumed, the incore detector system was capable of reliably detecting misloads severe enough to fail fuel during normal operation.

Fuel misloads involving a single fuel rod or fuel pellet were not evaluated as part of Reference 1. Such misloads, in general, will not be detectable using the incore detector system due to the very small power distribution perturbation. In terms of increased peaking factors and reduced DNBR values, however, the consequences of such misloads will be very small and limited to the affected fuel rod and the immediately adjacent fuel rods.

Detection of fuel misloads is, in part, a function of the number of available incore detector locations. Reference 1 demonstrated that the flux map review criteria of Table 1 are effective in detecting fuel misloads that could lead to fuel failures during normal operation. To enhance the probability that significant misloads will be detected, tighter review criteria are employed when the number of available detector locations is reduced.

The detectability assessments of Reference 1 confirm that the moveable detector system can reliably detect fuel misloads that could fail fuel during normal operation when the Table 1 review criteria are employed. Specifically, Reference 1 demonstrated that only a small fraction of 1% of misloads severe enough to fail fuel during normal operation would be undetected at startup using these limited review criteria. Furthermore, it was judged that even these “undetected” misloads would very likely be detected if other attributes of the startup power distribution measurement (e.g., tilts and reaction rate error contours) were considered along with the results of low power physics testing. Given that detection of >99% of misloads severe enough to fail fuel is expected using these review criteria, a radiological consequences analysis is deemed unnecessary. Failures in fresh fuel during startup would have negligible radiological consequences since there is only a small fission product inventory. Following startup, any fuel rod failures would occur gradually and would be detected by coolant activity monitoring. Since the number of potential fuel rod failures due to a core misload would be extremely small and such failures would occur gradually, any coolant activity releases would initially be well within the cleanup capacity of the plant. Any trend in increased coolant activity would warrant further investigation and evaluation. Therefore, the second acceptance criterion for this event would be satisfied since failures would be gradual, detectable, and the operations would be maintained within Technical Specification coolant activity guidelines.

15.4.7.4 Conclusion

Fuel misloads are prevented by manufacturing controls and core loading controls. In the unlikely event that a fuel misload should occur, the incore moveable detector system is capable of reliably detecting misloads that could fail fuel at normal operation conditions. Exceeding the review criteria herein would initiate an investigation to identify potential core anomalies. Any failures associated with an undetected fuel misload would be gradual, detectable, and the operations would be maintained within Technical Specification coolant activity guidelines.

15.4.8 SPECTRUM OF ROD CLUSTER CONTROL ASSEMBLY EJECTION ACCIDENTS

15.4.8.1 Identification of Causes and Accident Description

This accident is defined as the mechanical failure of a control rod mechanism pressure housing resulting in the ejection of a RCCA and drive shaft. The consequence of this mechanical failure is a rapid positive reactivity insertion together with an adverse core power distribution, possibly leading to localized fuel rod damage.

15.4.8.1.1 Design Precautions and Protection

Certain features in the CPNPP pressurized water reactors are intended to preclude the possibility of a rod ejection accident, or to limit the consequences if the accident were to occur. These include a sound, conservative mechanical design of the rod housings, together with a thorough quality control (testing) program during assembly, and a nuclear design which lessens the potential ejection worth of RCCAs, and minimizes the number of assemblies inserted at high power levels.

Mechanical Design

The mechanical design is discussed in Section 4.6. Mechanical design and quality control procedures intended to preclude the possibility of a RCCA drive mechanism housing failure are listed below:

1. Each full length control rod drive mechanism housing is completely assembled and shop tested at 4100 psi.

2. The mechanism housings are individually hydrotested after they are attached to the head adapters in the reactor vessel head, and are checked during the hydrotest of the completed reactor coolant system.

3. Stress levels in the mechanism are not affected by anticipated system transients at power, or by the thermal movement of the coolant loops. Moments induced by the design earthquake can be accepted within the allowable primary working stress range specified by the American Society of Mechanical Engineers (ASME) Code, Section III, for Class 1 components.

4. The latch mechanism housing and rod travel housing are each a single length of forged Type 304 stainless steel. This material exhibits excellent notch toughness at all temperatures which will be encountered.

A significant margin of strength in the elastic range together with the large energy absorption capability in the plastic range gives additional assurance that gross failure of the housing will not occur. The joints between the latch mechanism housing and head adapter, and between the latch mechanism housing and rod travel housing, are threaded joints reinforced by canopy type rod welds. Administrative regulations require periodic inspections of these (and other) welds.

Nuclear Design

Even if a rupture of a RCCA drive mechanism housing is postulated, the operation of a plant utilizing chemical shim is such that the severity of an ejected RCCA is inherently limited. In general, the reactor is operated with the RCCAs inserted only far enough to permit load follow. Reactivity changes caused by core depletion and xenon transients are compensated by boron changes. Further, the location and grouping of control RCCA banks are selected during the nuclear design to lessen the severity of a RCCA ejection accident. Therefore, should a RCCA be ejected from its normal position during full power operation, only a minor reactivity excursion, at worst, could be expected to occur.

However, it may be occasionally desirable to operate with larger than normal insertions. For this reason, a rod insertion limit is defined as a function of power level. Operation with the RCCAs above this limit guarantees adequate shutdown capability and acceptable power distribution. The position of all RCCAs is continuously indicated in the Control Room. An alarm will occur if a bank of RCCAs approaches its insertion limit or if one RCCA deviates from its bank. Operating instructions when the LO-LO alarm is received requires the shutdown margin to be verified within limits or to take actions to restore the shutdown margin in accordance with the Technical Specifications.

Reactor Protection

The reactor protection in the event of a rod ejection accident is provided by the high neutron flux trip (high and low setting) and the high rate of neutron flux increase trip. These protection functions are described in detail in Section 7.2.

Effects on Adjacent Housings

Disregarding the remote possibility of the occurrence of a RCCA mechanism housing failure, investigations have shown that failure of a housing due to either longitudinal or circumferential cracking would not cause damage to adjacent housings. The full length control rod drive mechanism is described in Section 3.9N.4.

Effects of Rod Travel Housing Longitudinal Failures

If a longitudinal failure of the rod travel housing should occur, the region of the position indicator assembly opposite the break would be stressed by the reactor coolant pressure of 2250 psia. The most probable leakage path would be provided by the radial deformation of the position indicator coil assembly, resulting in the growth of axial flow passages between the rod travel housing and the hollow tube along which the coil assemblies are mounted.

If failure of the position indicator coil assembly should occur, the resulting free radial jet from the failed housing could cause it to bend and contact adjacent rod housings. If the adjacent housings were on the periphery, they might bend outward from their bases. The housing material is quite ductile; plastic hinging without cracking would be expected. Housings adjacent to a failed housing, in locations other than the periphery, would not be bent because of the rigidity of multiple adjacent housings.

Effect of Rod Travel Housing Circumferential Failures

If circumferential failure of a rod travel housing should occur, the broken-off section of the housing would be ejected vertically because the driving force is vertical and the position indicator coil assembly and the drive shaft would tend to guide the broken-off piece upwards during its travel. Travel is limited by the missile shield, thereby limiting the projectile acceleration. When the projectile reached the missile shield it would partially penetrate the shield and dissipate its kinetic energy. The water jet from the break would continue to push the broken-off piece against the missile shield.

If the broken-off piece of the rod travel housing were short enough to clear the break when fully ejected, it would rebound after impact with the missile shield. The top end plates of the position indicator coil assemblies would prevent the broken piece from directly hitting the rod travel housing of a second drive mechanism. Even if a direct hit by the rebounding piece were to occur, the low kinetic energy of the rebounding projectile would not be expected to cause significant damage.

Possible Consequences

From the above discussion, the probability of damage to an adjacent housing must be considered remote. However, even if damage is postulated, it would not be expected to lead to a more severe transient since RCCAs are inserted in the core in symmetric patterns, and control rods immediately adjacent to the worst ejected rods are not in the core when the reactor is critical. Damage to an adjacent housing could, at worst, cause that RCCA not to fall on receiving a trip signal; however this is already taken into account in the analysis by assuming a stuck rod adjacent to the ejected rod.

Summary

The considerations given above lead to the conclusion that failure of a control rod housing, due either to longitudinal or circumferential cracking, would not cause damage to adjacent housings that would increase the severity of the initial accident.

15.4.8.1.2 Limiting Criteria

This event is classified as an ANS Condition IV incident (i.e., a limiting fault). See Section 15.0.1 for a discussion of ANS classifications. Due to the extremely low probability of a RCCA ejection accident, some fuel damage could be considered an acceptable consequence.

In view of the above experimental results, criteria are applied to ensure that there is little or no possibility of fuel dispersal in the coolant, gross lattice distortion, or severe shock waves. These criteria are:

1. Average fuel pellet enthalpy at the hot spot must remain less than 200 cal/gm for irradiated fuel. This bounds non-irradiated fuel, which has a slightly higher enthalpy limit.

2. Peak reactor coolant pressure less than that which could cause stresses to exceed the faulted condition stress limits.

3. Fuel melting will be limited to less than 10 percent of the fuel pellet volume at the hot spot even if the average fuel pellet enthalpy is below the limits of criterion 1 above.

15.4.8.2 Analysis of Effects and Consequences

Method of Analysis

The calculation of the RCCA ejection transient is performed in two stages, first an average core channel calculation and then a hot region calculation. The average core calculation is performed to determine the average power generation with time including the various total core feedback effects, i.e., Doppler reactivity and moderator reactivity. Enthalpy and temperature transients in the hot spot are then determined by multiplying the average core energy generation by the hot channel factor and performing a fuel rod transient heat transfer calculation. The power distribution calculated without feedback is pessimistically assumed to persist throughout the transient.

A detailed discussion of the method of analysis can be found in Reference 2.

Average Core Analysis

The spatial kinetics computer code, TWINKLE (Reference 4), is used for the average core transient analysis. This code solves the two group neutron diffusion theory kinetic equation in one, two or three spatial dimensions (rectangular coordinates) for six delayed neutron groups and up to 2,000 spatial points. The computer code includes a detailed multi-region, transient fuel-clad-coolant heat transfer model for calculations of point-wise Doppler and moderator feedback effects. In this analysis, the code is used as a one dimensional axial kinetics code since it allows a more realistic representation of the spatial effects of axial moderator feedback and RCCA movement. However, since the radial dimension is missing, it is still necessary to employ very conservative methods (described below) of calculating the ejected rod worth and hot channel factor.

Hot Spot Analysis

In the hot spot analysis, the initial heat flux is equal to the nominal times the design hot channel factor. During the transient, the heat flux hot channel factor is linearly increased to the transient value in 0.1 second, the time for full ejection of the rod. Therefore, the assumption is made that the hot spot before and after ejection are coincident. This is very conservative since the peak after ejection will occur in or adjacent to the assembly with the ejected rod, and prior to ejection the power in this region will necessarily be depressed.

The hot spot analysis is performed using the detailed fuel and clad transient heat transfer computer code, FACTRAN (Reference 5). This computer code calculates the transient temperature distribution in a cross section of a metal clad UO2 fuel rod, and the heat flux at the surface of the rod, using as input the nuclear power versus time from the TWINKLE code (as discussed above) and the local coolant conditions. The zirconium-water reaction is explicitly represented, and all material properties are represented as functions of temperature. A parabolic radial power distribution is used within the fuel rod.

FACTRAN uses the Dittus-Boelter or Jens-Lottes correlation to determine the film heat transfer before DNB, and the Bishop-Sandburg-Tong correlation (Reference 3) to determine the film

boiling coefficient after DNB. The Bishop-Sandburg-Tong correlation is conservatively used assuming zero bulk fluid quality. The DNBR is not calculated; instead the code is forced into DNB by specifying a conservative DNB heat flux. The gap heat transfer coefficient is calculated by the code; however, it adjusted in order to force the full power steady state temperature distribution to agree with the fuel heat transfer design codes.

System Overpressure Analysis

Because safety limits for fuel damage specified earlier are not exceeded, there is little likelihood of fuel dispersal into the coolant. The pressure surge may therefore be calculated on the basis of conventional heat transfer from the fuel and prompt heat generation in the coolant. Due to the very conservative method of analysis, the peak surge rate is high enough to cause the reactor coolant pressure to exceed the pressurizer safety valve actuation pressure; however, this condition exists only for a few seconds. The pressurizer water volume does not change significantly. Therefore, these transients are not sensitive to the initial pressurizer water volume.

The pressure surge was calculated generically (Reference 2) by first performing the fuel heat transfer calculation to determine the average and hot spot heat flux versus time. Using this heat flux data, a calculation was performed to determine the volume surge. Finally, the volume surge is simulated in a plant transient computer code. This code calculates the pressure transient taking into account fluid transport in the RCS and heat transfer to the steam generators. No credit is taken for the possible pressure reduction caused by the assumed failure of the control rod pressure housing.

15.4.8.2.1 Calculation of Basic Parameters

Input parameters for the analysis are conservatively selected on the basis of values calculated for this type of core. A summary of parameters used in the analysis is given in Table 15.4-3. The more important parameters are discussed below.

Ejected Rod Worths and Hot Channel Factors

The values for ejected rod worths and hot channel factors are calculated using either three dimensional static methods or by a synthesis method employing one dimensional and two dimensional calculations. Standard nuclear design codes are used in the analysis. No credit is taken for the flux flattening effects of reactivity feedback. The calculation is performed for the maximum allowed bank insertion at a given power level, as determined by the rod insertion limits. Adverse xenon distributions are considered in the calculation.

Appropriate margins are added to the ejected rod worth and hot channel factors to account for any calculational uncertainties, including an allowance for nuclear power peaking due to densification.

Reactivity Feedback Weighting Factors

The largest temperature rises, and hence the largest reactivity feedbacks occur in channels where the power is higher than average. Since the weight of a region is dependent on flux, these regions have high weights. This means that the reactivity feedback is larger than that indicated by a simple channel analysis. Physics calculations have been carried out for temperature

changes with a flat temperature distribution, and with a large number of axial and radial temperature distributions.

Reactivity changes were compared and effective weighting factors determined. These weighting factors take the form of multipliers which, when applied to single channel feedbacks, correct them to effective whole core feedbacks for the appropriate flux shape. No weighting is applied to the moderator feedback.

A conservative radial weighing factor is applied to the transient fuel temperature to obtain an effective fuel temperature as a function of time accounting for the missing spatial dimension. These weighting factors have also been shown to be conservative compared to three dimensional analysis (Reference 2).

Moderator and Doppler Coefficient

The critical boron concentrations and BOL and EOL were adjusted in the nuclear code in order to obtain moderator density coefficient curves that were conservative when compared to the actual design conditions for the plant. As discussed above, no weighting factor is applied to these results. The applicable MTCs modeled were +5 pcm/^{o}F at zero-power nominal Tavg and 0 pcm/^{o}F at full-power Tavg for the BOL cases. For the EOL cases, the applicable zero-power MTC was -16.817 pcm/^{o}F and the full-power MTC was -22.920 pcm/^{o}F.

The Doppler reactivity defect is determined using a one dimensional steady state computer code with a Doppler weighting factor of 1.0. The Doppler weighting factor will increase under accident conditions, as discussed above.

Delayed Neutron Fraction

Calculations of the effective delayed neutron fraction (β_{eff}) typically yield values no less than 0.75 percent at beginning-of-life and 0.50 percent at end-of-life. The accident is sensitive to β_{eff} if the ejected rod worth is equal to or greater than β_{eff} as in zero power transients. In order to allow for future cycles, pessimistic estimates of 0.55 percent at beginning of cycle and 0.44 percent at end of cycle were used in the analysis.

Trip Reactivity Insertion

The trip reactivity insertion includes the effect of one stuck RCCA. These values are reduced by the ejected rod reactivity. The shutdown reactivity was simulated by dropping a rod of the required worth into the core. The start of rod motion is assumed to occur 0.5 seconds after the high neutron flux trip point was reached.

The minimum design shutdown margin available for this plant at hot zero power (HZP) may be reached only at end-of-life in the equilibrium cycle. This value includes an allowance for the worst stuck rod, and adverse xenon distribution, conservative Doppler and moderator defects, and an allowance for calculational uncertainties. Physics calculations for this plant have shown that the effect of two stuck RCCAs (one of which is the worst ejected rod) is to reduce the shutdown margin by about an additional 1 percent Δk. Therefore, following a reactor trip

resulting from an RCCA ejection accident, the reactor will be subcritical when the core returns to HZP.

Depressurization calculations have been performed for a typical four-loop plant assuming the maximum possible size break (2.75 inch diameter) located in the reactor pressure vessel head. The results show a rapid pressure drop and a decrease in system water mass due to the break. The Safety Injection System is actuated on low pressurizer pressure within 1 minute after the break. The RCS pressure continues to drop and reaches saturation (1200 psi) in about 2 to 3 minutes. Due to the large thermal inertia of the primary and secondary system, there has been no significant decrease in the RCS temperature below no-load by this time, and the depressurization itself has caused an increase in shutdown margin by about 0.2 percent Δk due to the pressure coefficient. The cooldown transient could not absorb the available shutdown margin until more than 10 minutes after the break. The addition of borated safety injection flow starting 1 minute after the break is sufficient to ensure that the core remains subcritical during the cooldown.

Reactor Protection

As discussed in Section 15.4.8.1.1, reactor protection for a rod ejection is provided by high neutron flux trip (high and low setting) and high rate of neutron flux increase trip. These protection functions are part of the Reactor Trip System. No single failure of the Reactor Trip System will negate the protection functions required for the rod ejection accident, or adversely affect the consequences of the accident.

15.4.8.3 Environmental Consequences

The ejection of an RCCA constitutes a break in the RCS, located in the reactor pressure vessel head. The effects and consequences of loss of coolant accidents are discussed in Section 15.6.5. Following the RCCA ejection, the operator would follow the same emergency instructions as for any other loss of coolant accident to recover from the event.

Fission Product Release

It is assumed that fission products are released from the gaps of all rods entering DNB. In all cases considered, less than 15 percent of the rods entered DNB.

Pressure Surge

A detailed calculation of the pressure surge for an ejection worth of one dollar at beginning-of-life, hot full power, indicates that the peak pressure does not exceed that which would cause stress to exceed the faulted condition stress limits [2]. Since the severity of the present analysis does not exceed the “worst case” analysis, the accident for this plant will not result in an excessive pressure rise or further damage to the RCS.

Lattice Deformations

A large temperature gradient will exist in the region of the hot spot. Since the fuel rods are free to move in the vertical direction, differential expansion between separate rods cannot produce distortion. However, the temperature gradients across individual rods may produce a differential expansion tending to bow the midpoint of the rods toward the hotter side of the rod. Calculations

have indicated that this bowing would result in a negative reactivity effect at the hot spot since the core is under-moderated, and bowing will tend to increase the under-moderation at the hot spot. In practice, no significant bowing is anticipated, since the structural rigidity of the core is more than sufficient to withstand the forces produced. Boiling in the hot spot region would produce a net flow away from that region. However, the heat from the fuel is released to the water relatively slowly, and it is considered inconceivable that cross flow will be sufficient to produce significant lattice forces. Even if massive and rapid boiling, sufficient to distort the lattice, is hypothetically postulated, the large void fraction in the hot spot region would produce a reduction in the total core moderator to fuel ratio, and a large reduction in this ratio at the hot spot. The net effect would therefore be a negative feedback. It can be concluded that no conceivable mechanism exists for a net positive feedback resulting from lattice deformation. In fact, a small negative feedback may result. The effect is conservatively ignored in the analysis.

Radiological Consequences

The doses resulting from a rod ejection accident are based on a conservative fission product release to the reactor coolant of the gap activity shown in sheet 2 of Table 15.0-7 from 15 percent of the fuel rods in the core plus the core activity shown in sheet 2 of Table 15.0-7 from the assumed 0.375 percent core melt. The method of analysis complies with the requirements of Position 3 of Regulatory Guide 1.195.

Following a postulated rod ejection accident, two alternate activity release paths are considered when determining radiological consequences of the accident. The first release path is via Containment leakage resulting from release of activity from the primary coolant to the Containment. The second path assumes that the Reactor Coolant System remains intact and that the activity enters the secondary system due to tube leakage and then is released to the environment as contaminated steam and is dumped through the relief valves, since offsite power is assumed to be lost.

Prior to the accident, it is assumed that the plant has been operating with simultaneous fuel defects and steam generator tube leakage for a sufficient period of time to establish equilibrium levels of activity in the primary and secondary coolants equal to the Table 15.1-4 values.

Following a postulated rod ejection accident, the activity released from the pellet-clad gap due to failure of a portion of the fuel rods and the melted fuel is assumed to be instantaneously released to the primary coolant. The activity released to the primary coolant is assumed to be uniformly mixed throughout the coolant instantaneously. Thus, the total activity of the primary coolant is assumed to be immediately available for release from the RCS. Of the activity released to the Containment from the coolant through the rupture in the reactor vessel head, 100 percent is assumed to be mixed instantaneously throughout the Containment. Fifty (50) percent of the iodine activity released from the melted fuel is assumed to immediately plate out on Containment surfaces. The remaining activity is available for leakage from the Containment at the design leak rate of 0.10 percent of Containment volume per day for the first 24 hours, and at a rate of 0.05 percent of Containment volume per day for the duration of the accident. The only removal processes considered in the Containment for the activity remaining after the above plate out are radioactive decay and leakage from the Containment.

The model for the activity available for release to the atmosphere from the relief valves assumes that the release consists of the activity in the secondary coolant prior to the accident plus that fraction of the activity leaking from the primary coolant through the steam generator tubes

following the accident. The leakage of primary coolant to the secondary side of the steam generator is assumed to continue at its initial rate, which is assumed to be the same rate as the leakage prior to the accident. With the assumption of coincident loss of offsite power, activity is assumed to be released to the atmosphere from a steam dump through the relief valves until the Reactor Coolant System temperature and pressure are reduced sufficiently to allow operation of the Residual Heat Removal System at 11 hours.

A summary of parameters used in the analysis is given in Table 15.4-4.

Fuel melting, limited to less than the innermost 10 percent of the fuel pellet at the hotspot, is included in the design criteria to ensure that fuel dispersion into the coolant does not occur [1]. Even though centerline melting in a small fraction of the core is not expected, a conservative upper limit of fission product release from the core as a result of a rod ejection accident can be estimated.

The Regulatory Guide 1.195 limit of fission product release from the core for this very conservative case is determined using the following assumptions:

1. 100 percent of the noble gases and iodines in the clad gaps of those fuel rods experiencing clad damage (assumed to be 15 percent of the rods in the core) are released to the reactor coolant. The affected fuel rods are assumed to be operating at 1.65 times the core average and thus have 1.65 times the average fission product inventory. The core activities are presented in Table 15.0-7.

2. 25 percent of the iodines and 100 percent of the noble gases in the fuel that melts are assumed to be released to the reactor coolant and available for release via the containment building. 50 percent of the iodines and 100 percent of the noble gases in the fuel that melts are assumed to be available for release from the secondary systems via primary-to-secondary leakage. The core activities are presented in Table 15.0-7.

3. The fraction of fuel melting is conservatively assumed to be 0.375 percent of the core, as determined by the following method [1]:

    a. A conservative upper limit of 50 percent of the rods experiencing clad damage also may experience centerline melting (a total of 7.5 percent of the rods in the core).

    b. Of rods experiencing centerline melting, only a conservative maximum of the innermost 10 percent of the volume actually melts (equivalent to 0.5 percent of the core that could experience melting).

    c. A conservative maximum of 50 percent of the axial length of the rod experiences melting due to the power distribution (0.5 of the 0.75 percent of the core = 0.375 percent of the core).

4. Prior to the accident, the plant is assumed to be operating at full power with coincident fuel defects and steam generator tube leakage. The steam generator tube leak rate is assumed to be 1.0 gpm. The initial primary coolant and secondary liquid activity concentrations are given in Table 15.1-4.

5. Instantaneous mixing in the Containment of all activity released from the coolant is assumed.

6. Fifty (50) percent of the iodine activity released from the melted fuel to the Containment atmosphere immediately plates out on Containment surfaces.

7. The Residual Heat Removal System is brought into service at 11 hours, thus terminating steam releases.

8. Loss of offsite power is assumed and, 1,750,000 lb of steam are discharged from the secondary system through the relief valves, during the 11 hours following the accident. Steam dump is terminated after 11 hours.

9. All releases to the atmosphere are assumed to be at ground level.

10. Other assumptions are detailed in Table 15.4-4.

Based on the foregoing model, the thyroid and whole body doses from the containment leakage for this accident are conservatively calculated to be 20.0 rem and 0.082 rem, respectively, for the exclusion area boundary (EAB), and 28.0 rem and 0.043 rem, respectively, for the low population zone (LPZ). The thyroid and whole body doses from the secondary side releases for this accident are conservatively calculated to be 4.2 rem and 0.42, respectively, for the EAB, and 7.9 rem and 0.15 rem, respectively, for the LPZ. For each scenario, the doses at these distances are below the dose values of 6.3 rem whole body and 75 rem thyroid set forth in RG 1.195.

15.4.8.4 Conclusions

For Units 1 and 2, even on a pessimistic basis, the analyses indicate that the described fuel and clad limits are not exceeded. It is concluded that there is no danger of sudden fuel dispersal into the coolant. Since the peak pressure does not exceed that which would cause stresses to exceed the faulted condition stress limits, it is concluded that there is no danger of further consequential damage to the RCS. The analyses have demonstrated that upper limit in fission product release as a result of a number of fuel rods entering DNB amounts to 15 percent.

FLUX MAP REVIEW CRITERIA FOR A 4-LOOP CORE

Number of Available Detector Locations	Measured vs. Predicted Detector Reaction Rate Comparison[a]	Symmetric Thimble Reaction Rate Comparison[b]
55 to 58	10%	7%
49 to 54	8%	5%
44 to 48	6%	5%

a) The review criterion is the table value (%) or an absolute normalized reaction rate difference equal to the table value divided by 100% (e.g., 10%/100%=0.1), whichever is greater.

b) Applicable to symmetric thimbles with normalized reaction rates above 0.7. The review criterion is relative to the expected reaction rate difference.

15.5 INCREASE IN REACTOR COOLANT INVENTORY

Discussion and analysis of the following events are presented in this section:

1. Inadvertent operation of the Emergency Core Cooling System during power operation

2. Chemical and Volume Control System malfunction that increases reactor coolant inventory

3. A number of BWR transients. (Not applicable to the Comanche Peak Nuclear Power Plant (CPNPP)).

These events, considered to be American Nuclear Society (ANS) Condition II event (i.e., a fault of moderate frequency), cause an increase in reactor coolant inventory. Section 15.0.1 contains a discussion of ANS classifications.

15.5.1 INADVERTENT OPERATION OF THE EMERGENCY CORE COOLING SYSTEM DURING POWER OPERATION

15.5.1.1 Identification of Causes and Accident Description

Spurious Emergency Core Cooling System (ECCS) operation at power could be caused by operator error or a false electrical actuation signal. A spurious signal may originate from any of the safety injection actuation channels as described in Section 7.3.

Following the actuation signal, the suction of the coolant charging pumps is diverted from the volume control tank to the Refueling Water Storage Tank. The charging pumps then force highly concentrated boric acid solution from the Refueling Water Storage Tank, through the header and injection line and into the cold leg of each loop. The safety injection pumps also start automatically but provide no flow when the Reactor Coolant System (RCS) is at normal pressure. The passive injection system and the low head system also provide no flow at normal RCS pressure.

A Safety Injection Actuation System (SIAS) signal normally results in a reactor trip followed by a turbine trip. However, it cannot be assumed that any single fault that actuates the SIAS will also produce a reactor trip. If a reactor trip is generated by the spurious SIAS signal, the operator would consult the appropriate emergency operating procedure to determine if the spurious signal was transient or steady state in nature.

The emergency operating procedures clearly define the diagnostics for a spurious Safety Injection signal. These emergency procedures provide direction to the operator as to the specific actions to be taken based on measured process variables (e.g., pressure, temperature, etc.) so it is unlikely that any judgment errors will be made. Thus, by following the procedures, the operator would be able to diagnose the event and take the appropriate corrective action.

If the operator incorrectly diagnoses an event as a spurious SI signal, this could result in the termination of safety injection for an accident where safety injection is needed (e.g., LOCA). The consequences of this action and the system failures are given in WCAP-9691, “NUREG-0578 2.1.9.c, Transient and Accident Analysis”. If the operator incorrectly diagnoses a spurious safety injection event as some other accident, the emergency operating procedures for

that accident would be followed until it became apparent (when monitoring the process variables called for in the emergency procedure) that the wrong accident had been identified. The operator would then revert to the correct procedure and, based on the results of process variable monitoring, he would take the appropriate actions to bring the plant to a safe shutdown condition.

Following a spurious safety injection signal, the operator cannot reset SI until all the required conditions given in the emergency operating procedures are met. Also, an interlock exists which does not allow manual resetting of SI for at least 60 seconds.

If a loss of offsite power occurs after resetting safety injection, manual action will be required to load the engineered safety features equipment onto the diesel powered emergency busses. The procedures to be followed by the operator in performing this action have been incorporated in the CPNPP Emergency Operating Procedures for the manual reset of safety injection.

If the ECCS actuation instrumentation must be repaired, future plant operation would be in accordance with the Technical Specifications.

If the Reactor Protection System does not produce an immediate trip as a result of the spurious SIAS signal, the reactor experiences a negative reactivity excursion due to the injected boron causing a decrease in reactor power. The power mismatch results in a drop in T_{avg} and consequent coolant shrinkage causing pressurizer pressure and water level to drop. Load will decrease due to the effect of reduced steam pressure on load after the turbine throttle valve is fully open. If automatic rod control is used, these effects will be lessened until the rods have moved out of the core. The transient is eventually terminated by the Reactor Protection System low pressure trip or by manual trip.

The time to trip is affected by initial operating conditions including core burnup history which affects initial boron concentration, rate of change of boron concentration, and Doppler and moderator coefficients.

Recovery from this second case is made in the same manner as described for the case where the SIAS signal results directly in a reactor trip. The only differences are the lower T_{avg} and pressurizer pressure associated with the power mismatch during the transient. The time at which reactor trip occurs is of little concern for this transient. At lower loads coolant contraction will be slower resulting in a longer time to trip.

This event is non-limiting with respect to Departure from Nucleate Boiling (DNB) since the conditions resulting from injecting borated water into the RCS are beneficial with respect to DNB. Depending on the control systems in operation, core power and RCS temperatures either remain near the initial nominal conditions or decrease during this event. The RCS flow remains constant throughout the event. A decrease in RCS pressure is the only condition that may occur which would adversely affect DNB. However, for the decrease in RCS pressure that may occur, the effects are more than offset by beneficial reduction in power and temperature. The net effect is a DNB Ratio (DNBR) that remains near the initial DNBR or increases throughout the event.

The major concern resulting from an Inadvertent ECCS Actuation at Power event is the potential to violate the ANS Condition II acceptance criterion where an incident of moderate frequency should not generate a more serious plant condition without other faults occurring independently.

The pressurizer water volume increase for this event is a result of continuous safety injection flow. Operator action is required to terminate safety injection flow prior to filling the pressurizer, thus demonstrating that this ANS Condition II event does not propagate to a more serious plant condition. Therefore, this event is analyzed to demonstrate that sufficient time is available for the operator to take appropriate actions to preclude a pressurizer water-solid condition.

This event is classified as a Condition II incident (a fault of moderate frequency) as defined in Section 15.0.1.

15.5.1.2 Analysis of Effects and Consequences

Method of Analysis

The Inadvertent Actuation of the ECCS System at Power event is analyzed by employing the detailed digital computer code RETRAN (Reference 1). The code simulates the neutron kinetics, and models the reactor coolant system, pressurizer, pressurizer relief and safety valves, pressurizer spray, steam generator, steam generator safety valves and the safety injection system. The code computes pertinent plant variables including temperature, pressures, and power level.

The assumptions are as follows:

1. Initial operating conditions

   The initial reactor power is assumed at its maximum value consistent with the steady state full power plus 0.6 percent allowance for calibration and instrument errors. The initial pressurizer water level is at the full power value of 60% span plus 5% uncertainty allowance and pressurizer pressure is 30 psi lower than nominal. The initial RCS temperature is assumed at the full power value minus 6^{o}F uncertainty allowance.

2. Moderator and Doppler coefficients of reactivity

   This event is analyzed with the maximum reactivity feedback such that the most negative moderator temperature coefficient and most negative Doppler power coefficient are assumed.

3. Reactor Control System

   The Reactor Control System is assumed to be in the manual mode of operation.

4. Pressurizer Pressure and Level Control System

   Pressurizer sprays are assumed to be operable to increase the rate of pressurizer filling. The pressurizer sprays act to reduce the RCS pressure, thus increasing ECCS injection. The pressurizer heaters are assumed to be de-energized (the pressurizer heaters at CPNPP are automatically de-energized upon receipt of a safety injection signal by safety-related SSPS relays).

5. Boron injection

   At time zero two charging pumps inject borated water into the cold leg of each loop. The RCS pressure does not decrease to the point where the Safety Injection pumps could deliver flow to the RCS.

6. Reactor trip

   The reactor and turbine are assumed to trip upon receipt of the SIAS signal. Assuming a reactor trip on the SIAS signal and a turbine trip derived from the reactor trip minimizes the heat removal capability of the RCS, thereby maximizing the RCS inventory increase through SI flow and thermal expansion of the RCS fluid.

7. Pressurizer PORVs

   No credit is taken for any pressurizer PORV operation.

8. Operator Actions

   The first operator action assumed is the initiation of the opening of at least three of the four steam generator atmospheric relief valves (ARVs) within 8 minutes after the event initiation to control Tavg to the no-load temperature of 557°F.

   The operators are then assumed to secure ECCS within 14 minutes after the event initiation. Operator action is also required to take positive control of the Pressurizer Pressure and Level Control System.

Plant systems and equipment which are available to mitigate the effects of the accident are discussed in Section 15.0.8 and listed in Table 15.0-6. No single active failure in any of these systems or equipment will adversely affect the consequences of the accident.

15.5.1.3 Conclusions

The filling of the pressurizer is the acceptance criterion of concern for this analysis. This criterion is more conservative than preventing water relief through the Pressurizer Safety Valves (PSVs), as it is possible to fill the pressurizer at a pressure below the PSV set pressure.

Results of the analysis show for Units 1 and 2 that the pressurizer does not reach a water-solid condition as a consequence of the inadvertent operation of ECCS during power operation, provided that the operator initiates the opening of the ARVs within 8 minutes to reduce Tavg close to 557°F, and the SI flow is turned off within 14 minutes after the event initiation.

15.5.2 CHEMICAL AND VOLUME CONTROL SYSTEM MALFUNCTION THAT INCREASES REACTOR COOLANT INVENTORY

An increase in reactor coolant inventory which results from the addition of cold, unborated water to the RCS is analyzed in Section 15.4.6, Chemical and Volume Control System malfunction that results in a decrease in boron concentration in the reactor coolant. An increase in reactor coolant inventory which results from the injection of highly borated water into the RCS is

analyzed in Section 15.5.1, inadvertent operation of the Emergency Core Cooling System during power operation.

15.5.3 A NUMBER OF BWR TRANSIENTS

This section is not applicable to the CPNPP.

TABLE 15.5-1
HAS BEEN DELETED

15.6 DECREASE IN REACTOR COOLANT INVENTORY

Events which result in a decrease in reactor coolant inventory as discussed in this section are as follows:

1. Inadvertent opening of a pressurizer safety or relief valve.

2. Break in instrument line or other lines from reactor coolant pressure boundary that penetrate containment.

3. Steam generator tube failure.

4. Spectrum of boiling water reactor (BWR) steam system piping failures outside of Containment. (Not applicable to the CPNPP.)

5. Loss of coolant accident (LOCA) resulting from a spectrum of postulated piping breaks within the reactor coolant pressure boundary.

6. A number of BWR transients. (Not applicable to the CPNPP.)

15.6.1 INADVERTENT OPENING OF A PRESSURIZER SAFETY OR RELIEF VALVE

15.6.1.1 Identification of Causes and Accident Description

An accidental depressurization of the Reactor Coolant System (RCS) could occur as a result of an inadvertent opening of a pressurizer relief or safety valve. Since a safety valve is sized to relieve approximately twice the steam flow rate of a relief valve (i.e., 420,000 lb/hr vs. 210,000 lb/hr), and will therefore allow a much more rapid depressurization upon opening, the most severe core conditions resulting from an accidental depressurization of the RCS are associated with an inadvertent opening of a pressurizer safety valve. The flow of released coolant due to the inadvertent opening of a pressurizer safety valve is equivalent to approximately a 2.0 in. break in the RCS hot leg. It is shown [13, 14] that a hot leg break transient is much less severe than an equivalent sized break in the cold leg. Thus, the transient due to the inadvertent opening of a pressurizer safety valve would be much less severe than the small break cold leg transients discussed in Section 15.6.5. Initially the event results in a rapidly decreasing RCS pressure until this pressure reaches a value corresponding to the hot leg saturation pressure. At this time, the pressure decrease is slowed considerably. The pressure continues to decrease throughout the transient. The effect of the pressure decrease would be to decrease or increase the neutron flux depending on the moderator density feedback, but the Reactor Control System (if in the automatic mode) functions to maintain the power and average coolant temperature essentially constant until the reactor trip occurs. Initially, the pressurizer level increases due to expansion caused by the depressurization, and then decreases following the reactor trip.

The reactor may be tripped by the following Reactor Protection System signals:

1. Overtemperature N-16.

2. Pressurizer low pressure.

An inadvertent opening of a pressurizer safety valve is classified as an American Nuclear Society (ANS) Condition II event, a fault of moderate frequency. See Section 15.0.1 for a discussion of Condition II events.

15.6.1.2 Analysis of Effects and Consequences

Method of Analysis

This transient is analyzed using the RETRAN computer code (Reference 1).

Plant characteristics and initial conditions are discussed in Section 15.0.3. In order to give conservative results in calculating the departure from nucleate boiling ratio (DNBR) during the transient, the following assumptions are made:

1. The initial core power is assumed to be at the nominal value consistent with steady-state, full-power operation. The initial pressurizer pressure and vessel average temperature are assumed to be at the respective nominal values, and the reactor coolant flow is at the minimum measured flow value. Uncertainties in the initial conditions are accounted for in the DNBR limit value as described in Reference 2.

2. A zero moderator temperature coefficient of reactivity is assumed in order to provide a conservatively low amount of negative reactivity feedback due to changes in the moderator density. The spatial effect of void due to local or subcooled boiling is not considered in the analysis with respect to reactivity feedback or core power shape. These voids would tend to flatten the core power distribution.

3. The least negative Doppler coefficient of reactivity is assumed such that the resultant amount of negative feedback is conservatively low in order to maximize any power increase due to moderator reactivity feedback.

Plant systems and equipment which are necessary to mitigate the effects of RCS depressurization caused by an inadvertent safety valve opening are discussed in Section 15.0.8 and listed in Table 15.0-6.

Normal reactor control systems are not required to function. The Rod Control System is assumed to be in the manual mode in order to maximize the nuclear power increase and to prevent rod insertion prior to reactor trip. The Reactor Protection System functions to trip the reactor on the appropriate signal. No single active failure will prevent the Reactor Protection System from functioning properly.

15.6.1.3 Conclusions

For Units 1 and 2, the results of the analysis show that the pressurizer low pressure and the Overtemperature N-16 Reactor Protection System signals provide adequate protection against the RCS depressurization event.

15.6.2 BREAK IN INSTRUMENT LINE OR OTHER LINES FROM REACTOR COOLANT PRESSURE BOUNDARY THAT PENETRATE CONTAINMENT

There are no instrument lines connected to the RCS that penetrate the Containment. However, the 3 inch CVCS letdown line and grab sample lines from the hot legs of reactor coolant loops 1 and 4, and from the steam and liquid space of the pressurizer, do penetrate the Containment. The grab sample lines are provided with normally closed isolation valves on both sides of the Containment wall and are designed in accordance with the requirements of General Design Criterion 55.

The most severe pipe rupture with regard to radioactivity release during normal plant operation occurs in the Chemical and Volume Control System (CVCS). This Condition III event would be a complete severance of the 3 inch letdown line just outside containment, between the outboard letdown isolation valve and letdown heat exchanger (see Figure 9.3-10), at rated power condition with a maximum letdown rate of 140 gpm. The occurrence of a complete severance of the letdown line would result in a loss-of-reactor coolant through two letdown orifices at the rate of about 190 gpm, which is within the makeup capacity of any two of the three charging pumps (see Table 9.3-7, sheet 1). Two non-safety related pressure switches located in the CVCS letdown line provide a means for detecting a rupture of the line. A low pressure signal, initiated by the rupture, will activate an alarm on the main control board, alerting the operator of the rupture, causing him to manually isolate the system. No credit is taken for Engineered Safety Features System actuation. Frequent operation of the automatic Reactor Makeup System and increased charging flow will also provide the operator indication of the loss-of-reactor coolant. No transient analysis is performed for this accident.

The time required for the operator to identify the accident and initiate the closure of the letdown isolation valve is expected to be within 30 minutes after accident initiation including 10 seconds for the letdown isolation valve closure time. Reactor coolant is assumed to be released until the isolation valve is fully closed. It is conservatively assumed that 20.1 percent of the leaking coolant flashes to steam. All of the iodine in this steam is assumed to become airborne and is available for release to the atmosphere. All noble gases contained in the leaking primary coolant are available for release to the atmosphere. A ground level release was postulated with an atmospheric dilution factor of 1.6×10^{-4} sec/m^3 at the minimum EAB distance. The equilibrium concentration of radioactive nuclides in the reactor coolant is given in Table 15.1-4. Effects of a concurrent iodine spike are included in the analysis.

Based on the foregoing model, the doses at the EAB are conservatively calculated to be 6.2 rem to the thyroid and 0.05 rem to the whole body. The LPZ doses are conservatively calculated to be 1.0 rem to the thyroid and 0.007 rem to the whole body. As expected, the radiological consequences resulting from the failure of the 3 inch CVCS letdown line do not exceed a small fraction of the dose values set forth in 10CFR100.

In Mode 3, below 500 degrees F, with three letdown orifices open (in lieu of two), the doses at the EAB are conservatively calculated to be 9.4 rem to the thyroid and 0.07 rem to the whole body. The LPZ doses are conservatively estimated to be 1.5 rem to the thyroid and 0.01 rem to the whole body. As expected, the radiological consequences resulting from the failure of the 3 inch CVCS letdown line in Mode 3 do not exceed a small fraction of the dose values set forth in 10CFR100.

15.6.3 STEAM GENERATOR TUBE FAILURE

15.6.3.1 Identification of Causes and Accident Description

The accident examined is the complete severance of a single steam generator tube. This event is considered an ANS Condition IV event, a limiting fault (see Section 15.0.1) and is analyzed to demonstrate that the resulting radiological doses are within the guideline values of 10CFR100. Timely operator response is required to terminate the primary-to-secondary break flow and to ensure that the ruptured steam generator does not fill with water and flood the main steamlines. This criterion is important because the main steamlines and relief valves are not designed for liquid flow.

The accident is assumed to take place at power with the reactor coolant contaminated with fission products corresponding to continuous operation with a limited amount of defective fuel rods. The accident leads to an increase in contamination of the secondary system due to leakage of radioactive coolant from the RCS. In the event of a coincident loss of offsite power, or failure of the condenser dump system, discharge of activity to the atmosphere takes place via the steam generator safety and/or power operated relief valves.

In view of the fact that the steam generator tube material is Inconel-600 (for Unit 2) and Inconel-690 (for Unit 1), both of which are a highly ductile material, it is considered that the assumption of a complete severance of a tube is somewhat conservative. The more probable mode of tube failure would be one or more minor leaks of undetermined origin. Activity in the Steam and Power Conversion System is subject to continual surveillance and an accumulation of minor leaks which exceeds the limits established in the Technical Specifications is not permitted during unit operation.

The reactor operators are expected to determine that a steam generator tube rupture has occurred, and to identify and isolate the ruptured steam generator on a restricted time scale in order to minimize the contamination of the secondary system and to ensure the termination of the radioactive release to the atmosphere from the ruptured steam generator. In the following discussions, the steam generator with the ruptured U-tube is referred to as the ruptured steam generator. The operator is then expected to carry out the appropriate recovery procedures on a restricted time scale in order to terminate the primary-to-secondary break flow before the water level in the ruptured steam generator rises into the main steam system piping. Sufficient indications and controls are provided to enable the operator to carry out these functions satisfactorily.

Assuming normal operation of the various plant control systems, the following sequence of events is initiated by a tube rupture:

1. Pressurizer low pressure and low level alarms are actuated and charging pump flow is increased to maintain pressurizer level. On the secondary side, there is a steam flow/ feedwater flow mismatch prior to reactor trip as the feedwater flow to the faulted steam generator is reduced due to the break flow being supplied to that unit.

2. The steam generator blowdown liquid monitor and the condenser off gas radiation monitor will alarm, indicating a sharp increase in radioactivity in the secondary system and the steam generator blowdown liquid monitor will automatically terminate steam generator blowdown. The steam generator leak rate monitor will also provide an alarm.

3. Continued loss of reactor coolant inventory may result in an Overtemperature N-16 initiated turbine runback, eventually followed by a reactor trip signal being generated by either the Overtemperature N-16 or Low Pressurizer Pressure reactor trip signals. The resultant plant cooldown following reactor trip leads to a rapid decrease in the pressurizer level, and the safety injection actuation signal, initiated on low pressurizer pressure, follows soon after the reactor trip. The safety injection actuation signal automatically causes the termination of the normal feedwater supply and the initiation of the Auxiliary Feedwater System.

4. The reactor trip automatically trips the turbine and if offsite power is available, the steam dump valves open, permitting steam release to the condenser. In the event of a coincident station blackout, the steam dump valves would automatically close to protect the condenser. The steam generator pressure would rapidly increase, resulting in steam discharge to the atmosphere through the steam generator safety and/or power operated relief valves.

Operator Responses

The immediately apparent symptoms of a tube rupture accident, such as falling pressurizer pressure and level and increased charging pump flow, are also symptoms of small steamline breaks and loss of coolant accidents. Therefore, it is important for the operator to identify the accident as a steam generator tube rupture in order to execute the correct recovery procedure. The steam generator tube rupture event can be uniquely identified by alarms from the condenser offgas, steam generator blowdown, or main steamline radiation monitors. The steam generator leak rate monitor will also provide an alarm. In addition, following reactor trip, the narrow range water level will rise more rapidly in the faulted steam generator than in the other steam generators due to the primary-to-secondary break flow.

Following identification of the event as a steam generator tube rupture, the following operator responses are required to terminate the primary-to-secondary break flow and to terminate the event.

1. The ruptured steam generator is isolated to minimize the release of radioactivity. Isolation of the ruptured steam generator is accomplished by closing the main steam isolation valve, isolating auxiliary feedwater, and increasing the setpoint pressure of the atmospheric relief valve.

2. The operators then cool the RCS at the maximum rate using the steam dump valves if offsite power is available, or the atmospheric relief valve on the intact steam generators if offsite power is lost. The cooldown is continued until the core exit temperature is less than the saturation temperature of the ruptured steam generator. This action ensures that the RCS can be rapidly depressurized to terminate the break flow.

3. Following the termination of the maximum rate cooldown, the RCS is depressurized using the pressurizer sprays, if available, or a pressurizer power operated relief valve if offsite power has been lost. In accordance with the emergency operating procedures, the depressurization is continued until the RCS pressure is lower than the faulted steam generator pressure. The primary to secondary leakage flow is terminated when the RCS pressure is less than the pressure in the ruptured steam generator.

4. The Emergency Core Cooling System (ECCS) pumps are then secured to prevent the RCS from repressurizing and reestablishing the break flow.

5. Following the termination of the break flow, the operators initiate a controlled cooldown and depressurization of the RCS to maintain the RCS pressure less than the pressure in the ruptured steam generator, thus preventing any further leakage of RCS fluid into the ruptured steam generator.

15.6.3.1.1 Analysis of Effects and Consequences

Determination of Operator Response Times

Because the reactor operators are required to terminate the primary- to-secondary break flow in a restricted period of time, the time needed for the operators to complete the required actions is important in evaluating the effects of the postulated event. Operator responses are separated into four significant actions:

1. Identification and isolation of the faulted steam generator;

2. Initiation of RCS cooldown;

3. Initiation of RCS depressurization; and,

4. Termination of the ECCS flow.

Conservative time requirements for completion of each of the important actions listed above were determined through observation of numerous simulator exercises using licensed reactor operators.

Conservative times required to perform each of the significant actions listed above were determined to be:

1.	Identify and isolate the ruptured steam generator after initiation of the steam generator tube rupture event:	13 minutes
2.	Initiate the RCS cooldown after steam generator isolation:	5 minutes
3.	Initiate the RCS depressurization after the end of the RCS cooldown:	2 minutes
4.	Terminate Safety Injection Flow following the end of the RCS depressurization:	3 minutes

Method of Analysis

The postulated Steam Generator Tube Rupture event is analyzed to demonstrate that the operators can terminate the primary-to-secondary break flow in a time frame compatible with preventing the filling of the ruptured steam generator. The RETRAN02 computer code is used to

calculate the transient response. Additional details concerning the design-basis analysis methodology are contained in References 37, 38 and 39.

Assumptions for initial conditions, control and protection system setpoints, and offsite power availability are selected for conservatism with respect to the maximum liquid volume in the ruptured steam generator.

WCAP-10698-P-A [Ref. 37] concluded that higher decay heat was conservative for the SGTR margin-tooverfill analysis, and therefore 120% of the 1971 ANS decay heat curve should be used in future SGTR margin-to-overfill analyses. This was found to be non-conservative for Comanche Peak. The margin to overfill analysis was revised using a conservative lower decay heat rate. The decreased heat input minimized the ruptured SG mass release due to steaming.

The major analysis assumptions are summarized below:

1. Initial Operating Conditions

   The initial reactor power and RCS temperatures are assumed to be at their nominal operating values consistent with steady-state, full power operation. The initial RCS pressurizer pressure and level are assumed to be consistent with steady-state full power operation, including appropriate allowances for calibration and instrumentation errors. The initial water inventory in the ruptured steam generator is conservatively selected to minimize the margin to overfill.

2. ESF System Capacities

   The capacities of the ECCS components, i.e., the centrifugal charging pumps and the safety injection pumps, are conservatively maximized to increase the primary to secondary leak rate, thereby maximizing the liquid volume in the ruptured steam generator. The total auxiliary feedwater flow to the ruptured steam generator from the turbine-driven and motor-driven auxiliary feedwater pumps is also conservatively maximized.

3. Offsite Power

   Offsite power is assumed to be lost coincident with the reactor trip and turbine trip. Thus, the reactor coolant pumps begin to coast down immediately following the reactor trip and the pressurizer sprays are not available for RCS depressurization. The steam dump valves are also inoperable following the loss of offsite power.

4. Equipment Availability

   To conservatively increase the break flow rate, the pressure in the ruptured steam generator is maintained at or below the setpoint pressure of the atmospheric relief valve rather than that of the main steam safety valves. The atmospheric relief valves on all intact steam generators are available for cooling the RCS.

   The pressurizer power-operated relief valves and their associated block valves are assumed to be operable. Nitrogen accumulators are provided for the pressurizer PORVs should offsite power not be available.

5. Protection and Control Systems

The turbine and rod control systems are assumed to be in the manual mode of operation; the effects of automatic control have been bounded by the selection of conservative initial conditions. The Steam Generator Water Level Control System is assumed to function normally prior to reactor trip. If the steam generator water level controller were in manual, the faulted steam generator would be identified earlier, thus decreasing the maximum liquid volume. To maximize the liquid volume in the ruptured steam generator, the turbine is tripped and auxiliary feedwater actuation is initiated 30 seconds after the reactor trip. No delay time is assumed between the initiation of the auxiliary feedwater and ECCS systems and the delivery of fluid from these pumps.

6. Single Active Failure

The failure of one (Unit 1) or two (Unit 2) intact steam generator ARVs to open is the limiting single active failure with respect to filling the ruptured steam generator. This leaves two ARVs (Unit 1) or one ARV (Unit 2) on intact steam generators available for cooling the RCS. This assumed failure extends the time required to cool the RCS to the point that the RCS can be depressurized and the break flow terminated.

15.6.3.2 Environmental Consequences

Evaluation of the steam generator tube rupture event indicates that DNBR is not reached and, thus, no clad damage would be expected in this transient. This is consistent with the fact that when the reactor is at power, the reactor coolant pumps are operating and, for this event, only a small fraction of the total primary system fluid inventory has leaked to the secondary side. Thus, it is very unlikely that DNB would occur as a result of the reduced RCS flow. The RCS depressurization that results due to flow out of the tube rupture presents another possibility for obtaining a low DNBR. However, the depressurization that occurs in a steam generator tube rupture is much less than considered in the depressurization transient analyzed in Section 15.6.1 for the Inadvertent Opening of a Pressurizer Safety or Relief Valve. In the analysis of that event, it was determined that the DNBR remains above the limit value throughout the transient and, thus, no clad damage is expected. From this, it is concluded that no clad damage is expected in the steam generator tube rupture event.

At the time of event termination, the liquid volume in the ruptured steam generator is less than that required to fill the steam generator to the level of the steam generator outlet nozzle. Thus, the acceptance criterion of preventing the filling of the ruptured steam generator is satisfied.

A conservative analysis of the postulated steam generator tube rupture assumes the loss of offsite power. The scenario involves the release of steam from the secondary system caused by a turbine trip in conjunction with loss of main steam dump capabilities, and subsequent venting to the atmosphere through the atmospheric relief valves.

The limiting single active failure is chosen in order to maximize the amount of radioactivity released directly to the atmosphere. It has been demonstrated that no single active failure scenario results in the flooding of the main steamlines. Thus, the limiting single active failure for the steam generator tube rupture event is the failure to close of the atmospheric relief valve on the loop with the ruptured steam generator. After identifying the stuck open atmospheric relief valve, operations personnel are dispatched to locally close the atmospheric relief valve block

valve. For the environmental consequences analysis, it is assumed that the block valve is closed within 30 minutes after identifying the stuck open atmospheric relief valve, thus terminating the release of radioactive steam from the ruptured steam generator to the atmosphere. Following the closure of the block valve, the primary and secondary system pressures are equalized in a manner similar to that previously described. Equalization of the primary and secondary system pressures terminates the leakage flow into the ruptured steam generator in sufficient time to prevent filling the ruptured steam generator. The volume available prior to filling the ruptured steam generator is greater than for the previous scenario.

The time dependent mass releases used to assess the radiological consequences of the postulated steam generator tube rupture are calculated from the RETRAN02 thermal-hydraulic analysis described above. Time-dependent values of the leakage rate into the ruptured steam generator and the flashing fraction were also used to assess the radiological consequences for the 0-2 hour time period following the event. Following the closure of the atmospheric relief valve block valve, the additional radiological dose is due to the leakage from the primary system into the intact steam generators and the initial concentration of radioactivity contained in the intact steam generators. The steam releases from 2 hours to residual heat removal system (RHRS) cut-in are determined from mass and energy balances using the RCS and intact steam generator conditions. Following termination of break flow, the intact steam generators' ARVs are assumed to cool down the plant at less than the maximum allowable rate to the RHRS in-service temperature. The ruptured steam generator is assumed to be depressurized to the RHRS in-service pressure immediately after the cooldown of the RCS. The amount of steam released is determined from mass and energy balances; no changes in thermodynamic conditions are assumed from termination of tube flow until depressurization is started since the ruptured steam generator is isolated. Steam releases from all steam generators are considered terminated when the RHRS in-service conditions are reached.

Two separate iodine spikes are considered:

Case I — A reactor transient has occurred prior to the tube rupture and raised the primary coolant iodine concentration to 60 uCi/gm Dose Equivalent Iodine-131 (DEQ I-131). The resulting preaccident isotopic iodine concentrations are shown in Table 15.6-2.

Case II — The reactor trip or primary system depressurization associated with the postulated accident creates an iodine spike in the primary system. The spike is assumed to increase the iodine appearance rate (inleakage from the defective fuel rods to the primary coolant) to 335 times the equilibrium appearance rate. The concurrent iodine spike appearance rates are presented in Table 15.6-3.

The assumptions below are used to determine the initial primary and secondary activities and to calculate the activity released and the offsite doses for the postulated steam generator tube rupture accident.

1. The initial primary coolant iodine activity (i.e., prior to any iodine spike considerations) is assumed to be at 1.0 uCi/gm DEQ I-131.

2. The primary coolant activity has been leaking into the secondary side at one gpm for a period of time long enough to establish equilibrium activity concentrations in the steam generators.

3. All noble gas activity transported from the primary system to the secondary system is immediately released to the environment. The initial iodine activity in the water region of the ruptured steam generator increases over time due to the unflashed portion of the leakage.

4. Due to the pressure differential between the primary and secondary sides, a fraction of the primary coolant that is discharged to the defective steam generator flashes to steam. This flashed fraction does not mix with the steam generator water and, therefore, is not subjected to any iodine removal process in the steam generator. However, the flashed fraction experiences iodine removal in the condenser when that path is available.

5. Radioactive decay of parent iodines to noble gas products is not considered during the iodine spiking processes or as unflashed iodine accumulates in the steam generators.

6. A ground level release is assumed. No credit is taken for radioactive decay or cloud depletion due to ground deposition during plume transport.

7. Worst case, five percentile atmospheric dispersion factors are assumed.

8. A breathing rate of 3.5E-04 m^3/sec is assumed.

9. Conservative iodine partition factors of 0.01 and 0.15 are used in the steam generator and condenser, respectively, to account for iodine removal effects within those components.

10. The dose contribution from the intact generator is based upon the effects of iodine spiking and a 1 gpm primary-to-secondary leak rate lasting for 11 hours. The leakage is assumed to mix with the secondary side water.

11. Other assumptions are detailed in Table 15.6-1.

Based on the foregoing model, the thyroid and whole body doses at the EAB are conservatively calculated to be 40 rem and 0.14 rem, respectively, for the preaccident iodine spike case and 26 rem and 0.18 rem, respectively, for the concurrent iodine spike case. The thyroid and whole body doses at the LPZ are conservatively calculated to be 6.0 rem and 0.03 rem, respectively, for the preaccident iodine spike case and 4.0 rem and 0.03 rem, respectively, for the concurrent iodine spike case. As expected, the doses are well below the values of 300 rem to the thyroid and 25 rem to the whole body set forth in 10CFR100.

15.6.4 SPECTRUM OF BWR STEAM SYSTEM PIPING FAILURES OUTSIDE OF CONTAINMENT

This section is not applicable to the CPNPP.

15.6.5 LOSS OF COOLANT ACCIDENT RESULTING FROM A SPECTRUM OF POSTULATED PIPING BREAKS WITHIN THE REACTOR COOLANT PRESSURE BOUNDARY

15.6.5.1 Identification of Causes and Frequency Classification

A LOCA is the result of a pipe rupture of the RCS pressure boundary. For the analyses reported here, a major pipe break (large break) is defined as a rupture with a total cross-sectional area equal to or greater than 1.0 square feet (ft^2). This event is considered an ANS Condition IV event, a limiting fault, in that it is not expected to occur during the lifetime of the plant but is postulated as a conservative design basis (see Section 15.0.1).

A minor pipe break (small break), as considered in this section, is defined as a rupture of the reactor coolant pressure boundary (see Section 5.2) with a total cross-sectional area less than 1.0 ft^2 in which the normally operating charging system flow is not sufficient to sustain pressurizer level and pressure. This is considered a Condition III event, in that it is an infrequent fault which may occur during the life of the plant.

The Acceptance Criteria for the LOCA are described in 10CFR50.46 (Reference 1) as follows:

1. The calculated maximum fuel element cladding temperature shall not exceed 2200 °F.

2. The calculated total amount of hydrogen generated from the chemical reaction of the cladding with water or steam shall not exceed 0.01 times the hypothetical amount that would be generated if all the metal in the cladding cylinders surrounding the fuel, excluding the cladding surrounding the plenum volume, were to react.

3. The calculated total oxidation of the cladding shall nowhere exceed 0.17 times the total cladding thickness before oxidation.

4. Calculated changes in core geometry shall be such that the core remains amenable to cooling.

5. After any successful operation of the ECCS, the calculated core temperature shall be maintained at an acceptably low value and decay heat shall be removed for the extended period of time required by the long-lived radioactivity remaining in the core.

These criteria were established to provide significant margin in Emergency Core Cooling System (ECCS) performance following a LOCA. Reference 2 presents a study in regard to the probability of occurrence of RCS pipe ruptures.

In all cases for Comanche Peak Units 1 and 2, small breaks (less than 1.0 ft^2) yield results with more margin to the Acceptance Criteria limits than large breaks.

15.6.5.2 Best Estimate Large Break Loss of Coolant Analysis (BE-LBLOCA)

15.6.5.2.1 General

When the Final Acceptance Criteria (FAC) governing the loss-of-coolant accident (LOCA) for Light Water Reactors was issued in Appendix K of 10 CFR 50.46, both the Nuclear Regulatory Commission (NRC) and the industry recognized that the stipulations of Appendix K were highly conservative. That is, using the then accepted analysis methods, the performance of the Emergency Core Cooling System (ECCS) would be conservatively underestimated, resulting in predicted Peak Clad Temperatures (PCTs) much higher than expected. At that time, however, the degree of conservatism in the analysis could not be quantified. As a result, the NRC began a large-scale confirmatory research program with the following objectives:

1. Identify, through separate effects and integral effects experiments, the degree of conservatism in those models permitted in the Appendix K rule. In this fashion, those areas in which a purposely prescriptive approach was used in the Appendix K rule could be quantified with additional data so that a less prescriptive future approach might be allowed.

2. Develop improved thermal-hydraulic computer codes and models so that more accurate and realistic accident analysis calculations could be performed. The purpose of this research was to develop an accurate predictive capability so that the uncertainties in the ECCS performance and the degree of conservatism with respect to the Appendix K limits could be quantified.

Since that time, the NRC and the nuclear industry have sponsored reactor safety research programs directed at meeting the above two objectives. The overall results have quantified the conservatism in the Appendix K rule for LOCA analyses and confirmed that some relaxation of the rule can be made without a loss in safety to the public. It was also found that some plants were being restricted in operating flexibility by the overly conservative Appendix K requirements. In recognition of the Appendix K conservatism that was being quantified by the research programs, the NRC adopted an interim approach for evaluation methods. This interim approach is described in SECY-83-472. The SECY-83-472 approach retained those features of Appendix K that were legal requirements, but permitted applicants to use best-estimate thermal-hydraulic models in their ECCS evaluation model. Thus, SECY-83-472 represented an important step in basing licensing decisions on realistic calculations, as opposed to those calculations prescribed by Appendix K.

In 1998, the NRC Staff amended the requirements of 10 CFR 50.46 and Appendix K, “ECCS Evaluation Models”, to permit the use of a realistic evaluation model to analyze the performance of the ECCS during a hypothetical LOCA. This decision was based on an improved understanding of LOCA thermal-hydraulic phenomena gained by extensive research programs. Under the amended rules, best-estimate thermal-hydraulic models may be used in place of models with Appendix K features. The rule change also requires, as part of the LOCA analysis, an assessment of the uncertainty of the best-estimate calculations. It further requires that this analysis uncertainty be included when comparing the results of the calculations to the prescribed

acceptance criteria of 10 CFR 50.46. Further guidance for the use of best-estimate codes is provided in Regulatory Guide 1.157.

To demonstrate use of the revised ECCS rule, the NRC and its consultants developed a method called the Code Scaling, Applicability, and Uncertainty (CSAU) evaluation methodology (NUREG/CR-5249). This method outlined an approach for defining and qualifying a best-estimate thermal-hydraulic code and quantifying the uncertainties in a LOCA analysis.

A LOCA evaluation methodology for three- and four-loop Pressurized Water Reactor (PWR) plants based on the revised 10 CFR 50.46 rules was developed by Westinghouse with the support of EPRI and Consolidated Edison and has been approved by the NRC (WCAP-12945-P-A).

More recently, Westinghouse developed an alternative uncertainty methodology called ASTRUM, which stands for Automated Statistical TReatment of Uncertainty Method (WCAP-16009-P-A). This method is still based on the CQD methodology and follows the steps in the CSAU methodology (NUREG/CR-5249). However, the uncertainty analysis (Element 3 in the CSAU) is replaced by a technique based on order statistics. The ASTRUM methodology replaces the response surface technique with a statistical sampling method where the uncertainty parameters are simultaneously sampled for each case. The ASTRUM methodology has received NRC approval for referencing in licensing calculations in WCAP-16009-P-A.

The three 10 CFR 50.46 criteria (peak clad temperature, maximum local oxidation, and core-wide oxidation) are satisfied by running a sufficient number of WCOBRA/TRAC calculations (sample size). In particular, the statistical theory predicts that 124 calculations are required to simultaneously bound the 95th percentile values of three parameters with a 95-percent confidence level.

This analysis is in accordance with the applicability limits and usage conditions defined in Section 13-3 of WCAP-16009-P-A, as applicable to the ASTRUM methodology. Section 13-3 of WCAP-16009-P-A was found to acceptably disposition each of the identified conditions and limitations related to WCOBRA/TRAC and the CQD uncertainty approach per Section 4.0 of the ASTRUM Final Safety Evaluation Report appended to this topical report.

15.6.5.2.2 Method of Analysis

The methods used in the application of WCOBRA/TRAC to the large break LOCA with ASTRUM are described in WCAP-12945-P-A and WCAP-16009-P-A. A detailed assessment of the computer code WCOBRA/TRAC was made through comparisons to experimental data. These assessments were used to develop quantitative estimates of the code's ability to predict key physical phenomena in a PWR large break LOCA. Modeling of a PWR introduces additional uncertainties which are identified and quantified in the plant-specific analysis. WCOBRA/TRAC MOD7A was used for the execution of ASTRUM for Comanche Peak Units 1 and 2 (WCAP-16009-P-A).

WCOBRA/TRAC combines two-fluid, three-field, multi-dimensional fluid equations used in the vessel with one-dimensional drift-flux equations used in the loops to allow a complete and detailed simulation of a PWR. This best-estimate computer code contains the following features:

1. Ability to model transient three-dimensional flows in different geometries inside the vessel

2. Ability to model thermal and mechanical non-equilibrium between phases

3. Ability to mechanistically represent interfacial heat, mass, and momentum transfer in different flow regimes

4. Ability to represent important reactor components such as fuel rods, steam generators, reactor coolant pumps, etc.

A typical calculation using WCOBRA/TRAC begins with the establishment of a steady-state, initial condition with all loops intact. The input parameters and initial conditions for this steady-state calculation are discussed in the next section.

Following the establishment of an acceptable steady-state condition, the transient calculation is initiated by introducing a break into one of the loops. The evolution of the transient through blowdown, refill, and reflood proceeds continuously, using the same computer code (WCOBRA/TRAC) and the same modeling assumptions. Containment pressure is modeled with the BREAK component using a time dependent pressure table. Containment pressure is calculated using the COCO code (WCAP-8326 and WCAP-8327) and mass and energy releases from the WCOBRA/TRAC calculation.

The final step of the best-estimate methodology, in which all uncertainties of the LOCA parameters are accounted for to estimate a PCT, Local Maximum Oxidation (LMO), and Core-Wide Oxidation (CWO) at 95-percent probability, is described in the following sections.

1. Plant Model Development:

   In this step, a WCOBRA/TRAC model of the plant is developed. A high level of noding detail is used in order to provide an accurate simulation of the transient. However, specific guidelines are followed to ensure that the model is consistent with models used in the code validation. This results in a high level of consistency among plant models, except for specific areas dictated by hardware differences, such as in the upper plenum of the reactor vessel or the ECCS injection configuration.

2. Determination of Plant Operating Conditions:

   In this step, the expected or desired operating range of the plant to which the analysis applies is established. The parameters considered are based on a “key LOCA parameters” list that was developed as part of the methodology. A set of these parameters, at mostly nominal values, is chosen for input as initial conditions to the plant model. A transient is run utilizing these parameters and is known as the “initial transient”. Next, several confirmatory runs are made, which vary a subset of the key LOCA parameters over their expected operating range in one-at-a-time sensitivities. Because certain parameters are not included in the uncertainty analysis, these parameters are set at their bounding condition. This analysis is commonly referred to as the confirmatory analysis. The most limiting input conditions, based on these confirmatory runs, are then combined into the

model that will represent the limiting state for the plant, which is the starting point for the assessment of uncertainties.

3. Assessment of Uncertainty:

   The ASTRUM methodology is based on order statistics. The technical basis of the order statistics is described in Section 11 of WCAP-16009-P-A. The determination of the PCT uncertainty, LMO uncertainty, and CWO uncertainty relies on a statistical sampling technique. According to the statistical theory, 124 WCOBRA/TRAC calculations are necessary to assess against the three 10 CFR 50.46 criteria (PCT, LMO, CWO).

   The uncertainty contributors are sampled randomly from their respective distributions for each of the WCOBRA/TRAC calculations. The list of uncertainty parameters, which are randomly sampled for each time in the cycle, break type (split or double-ended guillotine), and break size for the split break are also sampled as uncertainty contributors within the ASTRUM methodology.

   Results from the 124 calculations are tallied by ranking the PCT from highest to lowest. A similar procedure is repeated for LMO and CWO. The highest rank of PCT, LMO, and CWO will bound 95 percent of their respective populations with 95-percent confidence level.

4. Plant Operating Range:

   The plant operating range over which the uncertainty evaluation applies is defined. Depending on the results obtained in the above uncertainty evaluation, this range may be the desired range or may be narrower for some parameters to gain additional margin.

15.6.5.2.3 Analysis Assumptions

The expected PCT and its uncertainty developed are valid for a range of plant operating conditions. The range of variation of the operating parameters has been accounted for in the uncertainty evaluation. Tables 15.6-4 and 15.6-5 summarize the operating ranges as defined for the proposed operating conditions which are supported by the Best-Estimate LBLOCA analysis for Comanche Peak Unit 1 and Unit 2, respectively. Tables 15.6-6 and 15.6-7 summarize the LBLOCA containment data used for calculating containment pressure (for both units). If operation is maintained within these ranges, the LBLOCA results developed in this report using WCOBRA/TRAC are considered to be valid. Note that some of these parameters vary over their range during normal operation (accumulator temperature) and other ranges are fixed for a given operational condition (T_{avg}).

15.6.5.2.4 Design Basis Accident

The Comanche Peak Units 1 and 2 PCT-limiting transients are both double-ended cold leg guillotine break which analyze conditions that fall within those listed in Table 15.6-4 (Unit 1) and Table 15.6-5 (Unit 2). Traditionally, cold leg breaks have been limiting for large break LOCA. This location is the one where flow stagnation in the core appears most likely to occur. Scoping

studies with WCOBRA/TRAC have confirmed that the cold leg remains the limiting break location (WCAP-12945-P-A).

The large break LOCA transient can be divided into convenient time periods in which specific phenomena occur, such as various hot assembly heatup and cooldown transients. For a typical large break, the blowdown period can be divided into the Critical Heat Flux (CHF) phase, the upward core flow phase, and the downward core flow phase. These are followed by the refill, reflood, and long-term cooling periods. Specific important transient phenomena and heat transfer regimes are discussed below, with the transient results shown in Figures 15.6-1 to 15.6-14 for Unit 1 and Figures 15.6-15 to 15.6-28 for Unit 2. (The PCT-limiting case for each unit was chosen to show a conservative representation of the response to a large break LOCA.)

1. Critical Heat Flux (CHF) Phase:

   Immediately following the cold leg rupture, the break discharge rate is subcooled and high (Figures 15.6-2, 15.6-3 for Unit 1 and 15.6-16, 15.6-17 for Unit 2). The regions of the RCS with the highest initial temperatures (core, upper plenum, upper head, and hot legs) begin to flash to steam, the core flow reverses and the fuel rods begin to go through departure from nucleate boiling (DNB). The fuel cladding rapidly heats up (Figure 15.6-1 for Unit 1 and 15.6-15 for Unit 2) while the core power shuts down due to voiding in the core. This phase is terminated when the water in the lower plenum and downcomer begins to flash (Figures 15.6-7 and 15.6-12 for Unit 1 and 15.6-21 and 15.6-26 for Unit 2, respectively). The mixture swells and intact loop pumps, still rotating in single-phase liquid, push this two-phase mixture into the core.

2. Upward Core Flow Phase:

   Heat transfer is improved as the two-phase mixture is pushed into the core. This phase may be enhanced if the pumps are not degraded, or if the break discharge rate is low due to saturated fluid conditions at the break. If pump degradation is high or the break flow is large, the cooling effect due to upward flow may not be significant. Figures 15.6-4 (Unit 1) and 15.6-18 (Unit 2) show the void fraction for one intact loop pump and the broken loop pump. Each figure shows that the intact loop remains in single-phase liquid flow for several seconds, resulting in enhanced upward core flow cooling. This phase ends as the lower plenum mass is depleted, the loop flow becomes two-phase, and the pump head degrades.

3. Downward Core Flow Phase:

   The loop flow is pushed into the vessel by the intact loop pumps and decreases as the pump flow becomes two-phase. The break flow begins to dominate and pulls flow down through the core, up the downcomer to the broken loop cold leg, and out the break. While liquid and entrained liquid flow provide core cooling, the top third of core vapor flow (Figure 15.6-5 for Unit 1 and Figure 15.6-19 for Unit 2) best illustrates this phase of core cooling. Once the system has depressurized to the accumulator pressure (15.6-6 for Unit 1 and 15.6-20 for Unit 2), the accumulators begin to inject cold borated water into the intact cold legs (Figure 15.6-9 for Unit 1 and 15.6-23 for Unit 2). During this period, due to steam upflow in the downcomer, a portion of the injected ECCS water is calculated to be

bypassed around the downcomer and out the break. As the system pressure continues to fall, the break flow, and consequently the downward core flow, is reduced. The core begins to heat up as the system pressure approaches the containment pressure and the vessel begins to fill with ECCS water (Figure 15.6-8 for Unit 1 and 15.6-22 for Unit 2).

4. Refill Period:

As the refill period begins, the core begins a period of heatup and the vessel begins to fill with ECCS water (Figures 15.6-9, 15.6-10 for Unit 1 and 15.6-23, 15.6-24 for Unit 2). This period is characterized by a rapid increase in cladding temperatures at all elevations due to the lack of liquid and steam flow in the core region. This period continues until the lower plenum is filled and the bottom of the core begins to reflood and entrainment begins.

5. Reflood Period:

During the early reflood phase, the accumulators begin to empty and nitrogen enters the system. This forces water into the core, which then boils, causing system re-pressurization, and the lower core region begins to quench (Figure 15.6-11 for Unit 1 and 15.6-25 for Unit 2). During this time, core cooling may increase due to vapor generation and liquid entrainment. During the reflood period, the core flow is oscillatory as cold water periodically rewets and quenches the hot fuel cladding, which generates steam and causes system re-pressurization. The steam and entrained water must pass through the vessel upper plenum, the hot legs, the steam generators, and the reactor coolant pumps before it is vented out of the break. This flow path resistance is overcome by the downcomer water elevation head, which provides the gravity driven reflood force. From the later stage of blowdown to the beginning of reflood, the accumulators rapidly discharge borated cooling water into the RCS, filling the lower plenum and contributing to the filling of the downcomer. The pumped ECCS water aids in the filling of the downcomer and subsequently supplies water to maintain a full downcomer and complete the reflood period. As the quench front progresses up the core, the PCT location moves higher into the top core region. As the vessel continues to fill, the PCT location is cooled and the early reflood period is terminated.

A second cladding heatup transient may occur due to boiling in the downcomer. The mixing of ECCS water with hot water and steam from the core, in addition to the continued heat transfer from the hot vessel and vessel metal, reduces the subcooling of ECCS water in the lower plenum and downcomer. The saturation temperature is dictated by the containment pressure. If the liquid temperature in the downcomer reaches saturation, subsequent heat transfer from the vessel and other structures will cause boiling and level swell in the downcomer. The downcomer liquid will spill out of the broken cold leg and reduce the driving head, which can reduce the reflood rate, causing a late reflood heatup at the upper core elevations. Figures 15.6-12 (Unit 1) and 15.6-26 (Unit 2) show only a slight reduction in downcomer level and indicates that a late reflood heatup does not occur.

15.6.5.2.5 Post Analysis of Record Evaluations

In addition to the analyses presented in this section, evaluations and reanalyses may be performed as needed to address computer code errors and emergent issues, or to support plant changes. The issues or changes are evaluated, and the impact on the Peak Cladding Temperature (PCT) is determined. The resultant increase or decrease in PCT is applied to the analysis of record PCT. The PCT, including all penalties and benefits is presented in Tables 15.6-8 (Unit 1) and 15.6-10 (Unit 2) for the large break LOCA. The current PCT is demonstrated to be less than the 10 CFR 50.46(b) requirement of 2200 ºF.

In addition, 10 CFR 50.46 requires that licensees assess and report the effect of changes to or errors in the evaluation model used in the large break LOCA analysis. These reports constitute addenda to the analysis of record provided in the UFSAR until the overall changes become significant as defined by 10 CFR 50.46. If the assessed changes or errors in the evaluation model results in significant changes in calculated PCT, a schedule for formal reanalysis or other action as needed to show compliance will be addressed in the report to the NRC.

Finally, the criteria of 10 CFR 50.46 requires that holders and users of the evaluation models establish a number of definitions and processes for assessing changes in the models or their use. Westinghouse, in consultation with the PWR Owner's Group (PWROG), has developed an approach for compliance with the reporting requirements. This approach is documented in WCAP-13451, Westinghouse Methodology for Implementation of 10 CFR 50.46 Reporting. Vistra OpCo provides the NRC with annual and 30-day reports, as applicable, for Comanche Peak Units 1 and 2. Vistra OpCo intends to provide future reports required by 10 CFR 50.46 consistent with the approach described in WCAP-13451.

15.6.5.2.6 Conclusions

It must be demonstrated that there is a high level of probability that the limits set forth in 10 CFR 50.46 are met. The demonstration that these limits are met is as follows:

(b)(1) The limiting PCT corresponds to a bounding estimate of the 95th percentile PCT at the 95-percent confidence level. The analysis confirms that 10 CFR 50.46 acceptance criterion (b)(1), i.e., "Peak Clad Temperature less than 2200 ºF", is demonstrated. The results are shown in Table 15.6-9 for Unit 1 and Table 15.6-11 for Unit 2.

(b)(2) The maximum cladding oxidation corresponds to a bounding estimate of the 95th percentile LMO at the 95-percent confidence level. The analysis confirms that 10 CFR 50.46 acceptance criterion (b)(2), i.e., "Local Maximum Oxidation of the cladding less than 17 percent", is demonstrated. The results are shown in Table 15.6-9 for Unit 1 and Table 15.6-11 for Unit 2.

(b)(3) The limiting core-wide oxidation (CWO) corresponds to a bounding estimate of the 95th percentile CWO at the 95-percent confidence level. The limiting Hot Assembly Rod (HAR) total maximum oxidation is 0.0 percent for both units. A detailed CWO calculation takes advantage of the core power census that includes many lower power assemblies. Because there is significant margin to the regulatory limit, the CWO value can be conservatively chosen as that calculated for the limiting HAR. A detailed CWO calculation is therefore not needed because

the outcome will always be less than the HAR value. The analysis confirms that 10 CFR 50.46 acceptance criterion (b)(3), i.e., “Core-Wide Oxidation less than 1 percent”, is demonstrated. The results are shown in Table 15.6-9 for Unit 1 and Table 15.6-11 for Unit 2.

(b)(4) 10 CFR 50.46 acceptance criterion (b)(4) requires that the calculated changes in core geometry are such that the core remains amenable to cooling. This criterion has historically been satisfied by adherence to criteria (b)(1) and (b)(2), and by assuring that fuel deformation due to combined LOCA and seismic loads is specifically addressed. It has been demonstrated that the PCT and maximum cladding oxidation limits remain in effect for Best-Estimate LOCA applications. The approved methodology (WCAP-12945-P-A) specifies that effects of LOCA and seismic loads on core geometry do not need to be considered unless grid crushing extends beyond the 44 assemblies in the low-power channel. This situation has not been calculated to occur for Comanche Peak Units 1 and 2. Therefore, acceptance criterion (b)(4) is satisfied.

(b)(5) 10 CFR 50.46 acceptance criterion (b)(5) requires that long-term core cooling be provided following the successful initial operation of the ECCS. Long-term cooling is dependent on the demonstration of continued delivery of cooling water to the core. The actions, automatic or manual, that are currently in place at these plants to maintain long-term cooling remain unchanged with the application of the ASTRUM methodology (WCAP-16009-P-A).

Based on the ASTRUM Analysis results (Tables 15.6-9 and 15.6-11), it is concluded that Comanche Peak Units 1 and 2 continue to maintain a margin of safety to the limits prescribed by 10 CFR 50.46.

15.6.5.3 Small Break Loss of Coolant Accident

15.6.5.3.1 Sequence of Events and System Operations

A LOCA can result from a rupture of the reactor coolant system (RCS) or of any line connected to that system up to the first isolation valve. Ruptures of small cross section will cause expulsion of the coolant at a rate that can be accommodated by the charging pumps. Breaks of greater size (up to 1 ft^2 area) are defined as small breaks and are analyzed with the NOTRUMP computer code. A rupture in the reactor coolant system results in the discharge to the containment of reactor coolant and associated energy. The result of this discharge is a decrease in coolant pressure in the reactor coolant system and an increase in containment temperature and pressure.

The reactor trip signal subsequently occurs when the pressurizer low pressure trip setpoint is reached. A safety injection system (SIS) signal is actuated when the appropriate pressurizer low pressure setpoint is reached, activating the Emergency Core Cooling System (ECCS) (assuming the most limiting single failure of ECCS equipment).

Before the break occurs, the unit is assumed to be in an equilibrium condition, (i.e., the heat generated in the core is being removed via the secondary system). In the small break LOCA, the blowdown phase of the small break occurs over a long time period. Thus for a small break LOCA, there are three characteristic stages: (1) a gradual blowdown in which the decrease in water level is checked by the inventory replenishment associated with safety injection, (2) core recovery, and (3) long-term recirculation. The heat transfer between the reactor coolant system and the secondary system may be in either direction, depending on the relative temperature. For the case of continued heat addition to the secondary side, the secondary side pressure increases and the main steam safety valves may actuate to reduce the pressure. Makeup to the secondary side is automatically provided by the auxiliary feedwater system. Coincident with the SIS, normal feedwater flow is stopped by closing the main feedwater control valves and tripping the main feedwater pumps. Emergency feedwater flow is initiated by starting the auxiliary feedwater pumps. The secondary side flow aids in the reduction of RCS pressure with the break being the primary means of heat removal. When the reactor coolant system depressurizes to approximately 600 psia, the accumulators begin to inject borated water into the reactor coolant loops. Reflecting the loss of offsite power assumption, the reactor coolant pumps are assumed to be tripped at the time of reactor trip, and the effects of pump coastdown are included in the blowdown analysis.

15.6.5.3.2 Small Break Evaluation Model

The NOTRUMP and LOCTA-IV computer codes are used to perform the analysis of LOCAs due to small breaks in the RCS. The NOTRUMP computer code, approved for this use by the U.S. Nuclear Regulatory Commission in May 1985 (Reference 1), is used to calculate the transient depressurization of the RCS as well as to describe the mass and enthalpy of the flow through the

break. This code is a one-dimensional general network code incorporating a number of features, including the utilization of nonequilibrium thermal calculation in all-fluid volumes, flow regime-dependent drift flux calculations with counter-current flooding limitations, mixture level tracking logic in multiple-stacked fluid nodes, and regime-dependent heat transfer correlations. Also, safety injection into the broken loop is modeled using the COSI condensation model (Reference 2). The NOTRUMP small-break LOCA ECCS evaluation model was developed to determine the RCS response to design basis small-break LOCAs and to address the NRC concerns expressed in NUREG-0611, “Generic Evaluation of Feedwater Transients and Small Break Loss-of-Coolant Accidents in Westinghouse-Designed Operating Plants.”

In NOTRUMP, the RCS is subdivided into fluid-filled control volumes (fluid nodes) and metal nodes interconnected by flow paths and heat transfer links. The transient behavior of the system is determined from the governing conservation equations of mass, energy, and momentum applied to these nodes. The broken loop is modeled explicitly, and the intact loops are lumped into a second loop. A detailed description of the NOTRUMP code is provided in References 1, 2, and 3.

In the NOTRUMP model, the reactor core is represented as a vertical stack of heated control volumes with an associated bubble rise model to permit a transient mixture height calculation. The multinode capability of the program enables an explicit and detailed spatial representation of various system components. In particular, it enables a proper calculation of the behavior of the loop seal during a LOCA.

Clad thermal analyses are performed with the LOCTA-IV code (Reference 4) which uses the RCS pressure, fuel rod power history, steam flow past the uncovered part of the core, and mixture height from the NOTRUMP hydraulic calculations as input. For all computations where core uncovery occurred, the NOTRUMP and LOCTA runs were terminated after the time the core mixture level reached the top of the core following uncovery.

A schematic representation of the computer code interfaces is given in Figure 15.6.5-29.

15.6.5.3.3 Input Parameters and Initial Conditions

Significant input parameters are given in Table 15.6.5-13.

The bases used to select the numerical values that are input parameters to the analysis have been conservatively determined from sensitivity studies (References 5, 6, and 7). In addition, the requirements of 10CFR50 Appendix K regarding specific model features were met by selecting models which provide a significant overall conservatism in the analysis. The assumptions made pertain to the conditions of the reactor and associated safety system equipment at the time that the LOCA occurs and include such items as the core-peaking factors and ECCS performance. Decay heat generated throughout the transient is also conservatively calculated.

For the small break LOCA (SBLOCA) analysis, loss of offsite power (LOOP) is assumed, which results in the limiting single failure assumption of the loss of one Emergency Diesel Generator (EDG) and a subsequent loss of one train of pumped Emergency Core Cooling System (ECCS) flow. The SBLOCA analysis assumes that reactor trip occurs coincident with the LOOP, which results in the following: (a) Reactor Coolant Pump (RCP) trip and coastdown and (b) Steam Dump System being inoperable.

The SBLOCA analysis is performed with a high nominal vessel average temperature (T_{avg}) value of 589.2°F. The high T_{avg} value chosen is evaluated to be applicable over the range of nominal vessel average temperature values (574.2°F to 589.2°F).

The safety injection (SI) system consists of gas pressurized accumulator tanks and pumped injection systems. The accumulators are modeled to inject borated water into the RCS when the RCS depressurizes to 603 psia. Minimum ECCS availability is assumed for the analysis from one centrifugal charging pump (CCP), one SI pump and one RHR pump. Assumed pumped SI characteristics as a function of RCS pressure used as boundary conditions in the analysis are shown in Table 15.6.5-14 and corresponding Figure 15.6.5-31 for break sizes less than 8.75 inches and Table 15.6.5-15 and corresponding Figure 15.6.5-32 for the 8.75 inch break case. For the break sizes less than 8.75 inches the broken loop safety injection flow is assumed to spill to RCS pressure and for the 8.75 inch break case the broken loop safety injection flow is assumed to spill to the containment back pressure of 0 psig. The ECCS was assumed to deliver to the RCS 22 seconds after the generation of the SI signal. This delay includes time required for sensor response, diesel generator startup and emergency power bus loading in case of a loss of offsite power coincident with an accident.

15.6.5.3.4 Small Break LOCA Results

The calculated peak clad temperature (PCT) resulting from the limiting small break LOCA is less than that calculated for the limiting large break for both Units. To insure that the worst possible small break size has been identified, calculations were performed for a spectrum of small breaks (2, 3, 4, 6 inch equivalent diameter cold leg breaks) as well as an 8.75 inch equivalent diameter accumulator line break for each unit. The results of these analyses are summarized in Tables 15.6.5-16 and 15.6.5-17 for Unit 1 and in Tables 15.6.5-18 and 15.6.5-19 for Unit 2.

Based on the results of these analyses, the limiting small break was determined to be a 4-inch diameter rupture of the RCS cold leg for both Unit 1 and Unit 2 with a PCT of 1013ºF and 1210ºF for Unit 1 and Unit 2, respectively. The clad did not rupture in any of the cases simulated.

Figures 15.6.5-33 through 15.6.5-80 present the principal parameters of interest for the small-break ECCS analyses. For all cases analyzed, the following transient parameters, where applicable, are presented (note that since there was no or minimal core uncovery for the 2, 6, and 8.75-inch cases, no LOCTA calculations were performed and no clad temperature or maximum local oxidation figures are provided for these breaks):

- Reactor Coolant System Pressure
- Core Mixture Height
- Core Exit Vapor Temperature
- Clad Temperature at Peak Clad Temperature Elevation
- Maximum Local ZrO2 Thickness

For the limiting (4-inch) breaks analyzed, the following additional transient parameters are presented:

- Total Reactor Coolant System Mass
- Core Exit Steam Flow Rate
- Total Break Flow and Safety Injection Flow
- Clad Surface Heat Transfer Coefficient at Peak Clad Temperature Elevation
- Fluid Temperature at Peak Clad Temperature Elevation

The maximum calculated PCT for all small breaks analyzed is 1210°F. These results are well below all corresponding acceptance criteria limits of 10CFR50.46.

15.6.5.4 Environmental Consequences

To demonstrate in a conservative manner that the operation of a nuclear power station does not present any undue radiological hazard to the general public, a hypothetical accident involving a gross release of fission products is evaluated. No mechanism for such a release has been postulated because it would require a number of simultaneous failures to occur in the engineered safety features. The core fission product inventory is assumed to be released into the containment as described in Regulatory Guide 1.195 [34]. Numerical values for the total core fission product inventory of the isotopes considered in calculating the radiation doses are listed in Table 15.0-7.

The radiological evaluation of this accident is divided into two parts: internal (thyroid) dose from inhalation of iodines in the leakage plume, and external (whole body) exposure as a result of immersion in the leakage plume.

The radiological consequences due to the release of core fission products during a postulated loss-of-coolant accident are evaluated in the following sections:

1. Radiological consequences of containment leakage

   The integrated thyroid doses and the integrated whole body doses are calculated using methods and assumptions in conformance with Regulatory Guide 1.195. The assumptions used in the analysis are listed below.

   a. Twenty-five percent of the equilibrium radioactive iodine inventory developed from maximum full-power operation of the core is immediately available for leakage from the reactor containment. Of this 25 percent, 91 percent is in the form of elemental iodine, 5 percent is in the form of particulate iodine, and 4 percent is in the form of organic iodides.

   b. All (i.e., 100 percent) of the equilibrium radioactive noble gas inventory developed from maximum full-power operation of the core is immediately available for leakage from the reactor containment.

   c. The effects of radiological decay during holdup in the containment are taken into account.

   d. The containment volume is divided into separate regions by concrete floors at different elevations (see Section 6.5.2). A radial gap between the concrete floors and the inner wall of the Containment Building permits a limited amount of convective mixing between these regions. The region not covered by containment spray is treated as a separate unsprayed volume which is assumed to mix with the volumes in the sprayed areas at a mixing rate of two turnovers per hour.

      The Containment Spray System is actuated by a high containment pressure signal. For a discussion of the sequence of events of spray system operation, see Section 6.5.2. A sodium hydroxide spray is used to reduce the amount of fission product iodine available for release during the LOCA. The containment spray solution is assumed to interact with the elemental iodine and particulate iodine. The mathematical models which calculate the iodine spray removal coefficients are presented in Section 6.5.2. For each region the calculated elemental iodine removal coefficients are above 10 hr^{-1}. The removal coefficient for elemental iodine used in the offsite dose calculation is limited to a maximum value of 10 hr^{-1} [22]. The calculated value of 11.4 hr^{-1} is used for the particulate iodine removal coefficient, until a DF of 50 is reached at which time the particulate removal coefficient is reduced by a factor of 10. The elemental iodine removal effectiveness may be expected to diminish after the concentration in the containment atmosphere has been reduced by several orders of magnitude. The elemental iodine removal effectiveness of the spray system is conservatively

assumed to cease after a decontamination of 100 in the containment atmosphere has been achieved.

e. The iodine and noble gases available for release to the environment are assumed to leak from the Containment at a maximum leak rate of 0.10 percent of the containment volume per day for the first 24 hours, and at 0.05 percent of the containment volume per day for the duration of the accident.

f. The duration of the accident is considered to be 30 days.

g. A ground-level release is assumed. Atmospheric dilution factors are discussed in Section 2.3 [23] and listed in Table 15.6-20.

h. No credit is taken for depletion of fission products in the plume due to ground deposition or radioactive decay in transit.

i. For the first 8 hours after the accident, the breathing rate of persons offsite is assumed to be 3.5×10^{-4} cubic meters per second (m3/sec). Eight to 24 hours following the accident, the breathing rate is assumed to be 1.8×10^{-4} m^3/sec. From 24 hours through 30 days after the accident, the rate is assumed to be 2.3×10^{-4} m^3/sec.

j. The mathematical model and dose conversion factors presented in Appendix 15B are used for evaluating the radiological consequences of the LOCA

k. Other assumptions are detailed in Table 15.6-20.

Using the assumptions presented above and the mathematical models presented in Appendix 15B, the doses at the EAB were conservatively calculated to be 46.4 rem to the thyroid and 0.655 rem to the whole body; the doses at the LPZ were conservatively calculated to be 18.7 rem to the thyroid and 0.224 rem to the whole body.

2. Radiological consequences of engineered safety features equipment leakage outside containment.

Following a postulated LOCA, a potential source of fission product release is the leakage of water from engineered safety features (ESF) equipment located outside the containment. Such leakage could occur during the recirculation phase through components such as pump flanges, valves, and heat exchangers. The fission products could then be released from the water into the atmosphere resulting in offsite radiological consequences that contribute to the total dose from the LOCA.

An analysis of the offsite effects attributable to ESF equipment leakage is performed based on the following conservative assumptions:

a. 50 percent of the halogens originally present in the core are intimately mixed with the coolant water and are assumed to be available for release through ESF equipment outside containment (see Table 15.6-21).

b. The leakage from all ESF components is conservatively assumed to start 10 minutes after the LOCA and continue for the duration of the accident at a rate of 2 gallons per minute.

c. An iodine partition factor of 0.1 is assumed. This factor is taken as the fraction of iodine in the leakage that becomes airborne.

d. Gaseous radioactivity released to rooms housing the leaking components is considered to be immediately swept away by the ventilation system and released to the atmosphere. (See Section 9.4.5 and Figures 1.2-16, 1.2-35 and 9.4-9).

e. An iodine adsorber efficiency of 95 percent is applied since the ventilation exhaust passes through HEPA filters and iodine adsorbers prior to release to the atmosphere. The iodine adsorbers are designed to the requirements of NRC Regulatory Guide 1.52 (See Appendix 1A(B)) as discussed in Section 9.4.3.

f. No credit is taken for an elevated release; all meteorological parameters are considered to be identical to those previously defined in this section.

Based upon the foregoing model, the thyroid and whole body dose contributions due to ESF equipment leakage are conservatively calculated to be 12.1 rem and 0.0402 rem, respectively, for the EAB. The LPZ doses are conservatively calculated to be 24.8 rem to the thyroid and 0.0266 rem to the whole body.

3. Environmental consequences of releases through the containment pressure relief line in the event of a LOCA

An analysis of the radioactive effluents escaping the Containment to the environment after a LOCA, via the line through the controlled access area exhaust system, was performed using the following assumptions:

a. The maximum containment air/steam mass release to the environment was conservatively calculated assuming containment pressures for a large break LOCA, and critical flow via the 3-3/8 inch orifice plate at the inlet to the pressure relief system ductwork. No credit was taken for line losses in the ductwork or two butterfly valves.

b. Only reactor coolant activity is assumed to be released. It was conservatively assumed that all iodine and noble gas activity in the primary coolant was instantaneously released to the containment atmosphere.

c. The primary coolant iodine activity is assumed to be 1.0 micro curie per gram dose equivalent I-131. The noble gas activity is based on operation with 1% fuel defects. The activity concentrations are presented in Table 15.1-4.

d. The containment pressure relief line isolation valve closure time including instrumentation delays will not exceed 5 seconds. The analysis did not consider the reduction of mass flow during the valve closure time of five seconds; full flow was assumed until the lapse of five seconds.

e. No credit was taken for radioactive decay.

f. No credit was taken for an elevated release.

Based on the foregoing assumptions, the doses to the thyroid and whole body were both conservatively calculated to be less than 1 rem at the exclusion area boundary. The doses from this accident are well within the values set forth in 10CFR100.

4. Total dose due to a postulated LOCA

The total dose attributed to a postulated LOCA is the combined doses due to containment leakage ESF equipment leakage, and releases through the containment pressure relief line. The combined EAB doses are 59.0 rem to the thyroid and 0.70 rem to the whole body. The combined LPZ doses are 44.0 rem to the thyroid and 0.25 rem to the whole body. As expected, the doses are below the values set forth in 10CFR100.

The dose to personnel engaging in mineral extraction operations within the exclusion area, in the event of a postulated LOCA, would be less than the dose values of 300 rem to the thyroid and 25 rem to the whole body set forth in 10CFR100.

5. Dose to the control room occupants

In the event of a Design Basis Accident (DBA), the safety injection actuation signal or a high radiation signal from the control room air intake monitors will initiate emergency recirculation and pressurization of the Control Room air conditioning system. Later, the emergency ventilation air makeup system can be brought into operation as described in Section 9.4.1.

The control room doses were analyzed for various design basis accidents. It was determined that the LOCA doses represent the limiting case. Therefore the methodology and the doses calculated for the LOCA are reported here.

The following assumptions are applied in the calculations of the dose to the control room occupants following the LOCA:

a. The basic assumptions presented in Items 1 and 2, above, are applied, except a constant breathing rate of 3.5×10^{-4} m^3/sec is assumed throughout the accident.

b. The control room pressurization (air intake) and recirculation iodine adsorbers are assigned a 99 percent decontamination efficiency for both elemental and organic iodines in accordance with Table 2 of Regulatory Guide 1.52 (See Appendix 1A(B)). The pressurization adsorbers are arranged in series with the recirculation adsorbers (see Figure 9.4-1) during the emergency pressurization mode, thus providing an equivalent decontaminating efficiency in excess of 99 percent for both elemental and organic iodines from the pressurization makeup air.

c. The control room air-conditioning system runs either in the emergency recirculation mode or the emergency ventilation mode during a LOCA.

d. During the emergency recirculation mode of operation, a constant air intake flow rate of 800 ft^3/min is assumed. This makes up for losses caused by leaks and maintains the control room atmosphere at a positive pressure of 0.125 inch water gauge relative to adjacent areas.

Since both recirculation trains are actuated by the safety injection signal, the outside air intake flow rate during dual train operation is conservatively estimated to be 1600 cfm. If both trains are assumed to operate for one hour, the calculated thyroid dose would decrease, due to the additional iodine filtration. The calculated whole body gamma and beta skin doses would increase slightly due to the additional intake of outside air. In both cases, the calculated doses remain below the limits specified in 10 CFR 50, Appendix A, "General Design Criteria for Nuclear Power Plants," Criterion 19. The reported control room doses are the higher values of the two cases.

e. During the emergency ventilation mode of operation, 3800 ft^3/min of outdoor air is used to introduce fresh air into the control room.

f. The emergency ventilation mode of operation is under administrative control so that the dose to the control room occupants is minimized, and the need for air change is satisfied.

The operating mode sequence used in this analysis is as follows:

Time Period	Operating Mode	Time in Mode	Air Intake Flow Rate	Filtered Recirculation Flow Rate
0 to 96 hours[(a)]	Emergency recirculation	96 hours	800 ft^3/min	7200 ft^3/min
96 to 117 hours	Emergency ventilation	21 hours	3800 ft^3/min	4200 ft^3/min
117 to 720 hours	Emergency recirculation	603 hours	800 ft^3/min	7200 ft^3/min

a) Since both recirculation trains are actuated by the SI signal, one train must be turned off manually by the operators within one (1) hour.

g. The distance from the Containment to the control room air intake is 94 feet, and the air intake is located 56 feet above ground. The distance from the primary plant vent stack (i.e. the ESF leakage release point) to the closest air intake is 138 ft.

h. Atmospheric dilution factors are determined from the following equation based on Reference [24]:

$$X/Q = [U(\pi\sigma_y \sigma_z + A/(K+2)]^{-1}$$

where:

U = wind speed at an elevation of 10 meters (m/sec)

σ_y, σ_z = standard deviation of the gas concentration in the horizontal and vertical crosswind directions, respectively, both being evaluated at a distance of 94 feet for the containment leakage source and at a distance of 138 feet for the ESF leakage source

$$K = \frac{3}{(S/D)^{1.4}}$$

S = distance between containment surface or primary plant vent and closest control room intake

D = diameter of Containment for the containment leakage source and a combination of portions of the Containment and Auxiliary Building for the ESF leakage source

A = projected area of Containment Building (3265 m^2) for the containment leakage source and 2088 m^2 for the ESF leakage source

Table 15.6-22 summarizes the X/Q values calculated utilizing this expression.

i. The CPNPP CREFS design is zone isolation, with filtered recirculation air, and with a positive pressure. This design maximizes the iodine protection factors and minimizes the dose from iodine. The total unfiltered infiltration rate in the control room is conservatively assumed to be 27 cfm, including 10 cfm due to ingress/egress, 2 cfm leakage from the ductwork passing through the control room pressure boundary, and 15 cfm from other sources. Filtered inleakage through the closed inlet bubble tight dampers due to the pressure differential is conservatively included for the impact on whole body due to noble gases. Though negligible, any inleakage through the bubble tight dampers will be filtered by the recirculation filtration units.

Because the control room door ingress/egress is to a stairwell which is equivalent to a two-door vestibule, backflow will not occur with the CPNPP CREFS design and the 10 cfm is not applicable per SRP 6.4. The ductwork has all welded joints which were leak tested prior to operation. Therefore, the assumed unfiltered inleakage from adjacent areas is conservative with respect to the SRP review criteria.

j. Habitability of the control room is based on the following occupancy factors:

Time Period	Occupancy Factor
0 to 24 hours	1.0
1 to 4 days	0.6
4 to 30 days	0.4

k. The air volume in the control room used to determine exposures to operators is 423,032 ft^3.

l. The models for the major contributors to the control room dose are provided in Appendix 15B.

Using the above assumptions and procedures, the thyroid dose is conservatively calculated to be 40.0 rem in the control room for the duration of the accident. The thyroid dose can be further reduced by the use of the available respiratory protection equipment. The total whole body gamma dose is conservatively calculated to be 1.2 rem. This calculated dose includes whole body dose contributions from containment sources (both direct and scattered radiation), the external passing cloud, control room atmosphere, activity buildup on filters, and streaming through doors and penetrations. These calculated doses are less than the limiting values specified in Regulatory Guide 1.195.

The skin dose received in the control room during the accident period is conservatively calculated to be 13.0 rem. This calculated beta skin dose is less than the 50 rem limit allowed by Regulatory Guide 1.195 if special protective clothing and eye protection is not used. However, special protective clothing and eye protection are provided for use, if required, to reduce the beta skin doses to the operators.

6. Environmental consequences of containment purging to control containment hydrogen concentration after a LOCA

   Purging of the containment atmosphere for controlling potential hydrogen accumulation in the Containment following a postulated LOCA is not required. Thus, an analysis of the radiological consequences of containment purging is not provided.

15.6.6 A NUMBER OF BWR TRANSIENTS

This section is not applicable to the CPNPP.

TABLE 15.6-1
PARAMETERS FOR POSTULATED STEAM GENERATOR TUBE RUPTURE ACCIDENT ANALYSIS

(Sheet 1 of 2)

	Parameter	Value
1.	Data and Assumptions Used to Estimate Radioactive Source Term For the Postulated Steam Generator Tube Rupture Accident	
	a. Steam generator tube leak prior to and during accident (gpm)	1.0
	b. Offsite power	lost on reactor trip
2.	Data and Assumptions Used to Estimate Activity Released to the Atmosphere	
	a. Iodine partition factor in steam generators prior to and during accident	0.01
	b. Iodine partition factor in condensers prior to accident	0.15
	c. Duration of plant cooldown by secondary system after accident (hr)	11
3.	Dispersion Data	
	a. Exclusion area boundary and low population zone distances	2080 m and 4 miles
	b. x/Q (sec/m^3) 0 - 2 hours (EAB) 0 - 8 hours (LPZ) 8 - 24 hours (LPZ)	 1.6×10^{-4} 2.4×10^{-5} 1.6×10^{-5}
4.	Dose Data	
	a. Method of dose calculation	See Appendix 15B
	b. Dose conversion assumptions	See Appendix 15B

TABLE 15.6-1
PARAMETERS FOR POSTULATED STEAM GENERATOR TUBE RUPTURE ACCIDENT ANALYSIS

(Sheet 2 of 2)

Parameter	Value
c. Doses (rem)	
With preaccident iodine spike	
@ exclusion area boundary	
(0 - 2 hours)	
Thyroid inhalation	40.0
Whole body gamma	0.14
@ low population zone	
(0 - 8 hours)	
Thyroid inhalation	6.0
Whole body gamma	0.03
With concurrent iodine spike	
@ exclusion area boundary	
(0 - 2 hours)	
Thyroid inhalation	26.0
Whole body gamma	0.18
@ low population zone	
(0 - 8 hours)	
Thyroid inhalation	4.0
Whole body gamma	0.03

TABLE 15.6-2
PREACCIDENT IODINE SPIKE CONCENTRATION IN THE PRIMARY COOLANT[a]

Spike Isotope	Preaccident Iodine Concentration (μCi/gm)
I-131	46.1
I-132	49.2
I-133	73.8
I-134	10.7
I-135	40.6

a) This concentration corresponds to 60 μCi/gm Dose Equivalent I-131, the maximum allowed at Rated Thermal Power by the Technical Specifications.

TABLE 15.6-3
IODINE APPEARANCE RATE TO THE REACTOR COOLANT AFTER THE ACCIDENT

Isotope	Iodine Appearance Rate[(a)] (Ci/min)
I-131	151.1
I-132	513.2
I-133	294.5
I-134	237.2
I-135	232.2

a) Corresponds to 335 times the equilibrium appearance rate based on operation with reactor coolant activity at 1.0 uCi/gm Dose Equivalent I-131.

15.7 RADIOACTIVE RELEASE FROM A SUBSYSTEM OR COMPONENT

15.7.1 RADIOACTIVE GAS WASTE SYSTEM LEAK OR FAILURE

15.7.1.1 Identification of Causes and Accident Description

The Gaseous Waste Processing System (GWPS), as discussed in Chapter 11, is designed to remove fission product gases from the reactor coolant. The system consists of a closed loop with waste gas compressors, hydrogen recombiners, waste gas decay tanks for service at power and other waste gas decay tanks for service at shutdown and startup.

The accident is defined as an unexpected and uncontrolled release of radioactive xenon and krypton fission product gases stored in a waste decay tank as a consequence of a failure of a single gas decay tank or associated piping.

Nonvolatile fission product concentrations are greatly reduced as the coolant is passed through the purification demineralizers. An iodine removal factor of 10 is expected in the mixed bed demineralizers, and an iodine partition factor of 100 is expected between the liquid and vapor phases in the volume control tank. Based on the above analysis and operating experience at Yankee-Rowe and Saxton, activity stored in a gas decay tank consists of the noble gases released from the processed coolant and only negligible quantities of less volatile isotopes.

15.7.1.2 Analysis of Effects and Consequences

The maximum activity in a single gas decay tank, the assumptions on which the activity is based, and the radiological consequences resulting from the release of this activity are discussed in Section 15.7.1.3.

15.7.1.3 Environmental Consequences

With the exception of the gas decay tank inventory assumption, the assumptions and equations delineated in Regulatory Guide 1.24 and summarized in Table 15.7-1 are used to evaluate the radiological consequences resulting from the postulated tank rupture. The noble gas inventory in the tank at the time of the rupture is assumed to be the activity in a single waste gas decay tank immediately after it has been isolated from the GWPS (see Table 15.7-2).

The GWPS is designed with sufficient tank capacity to store radioactive gases generated by the plant to allow for holdup of the gases.

The system is also designed to operate so that release of the maximum activity in any one gas decay tank, from a rupture of the tank, will not result in offsite doses that exceed the values set forth in l0CFRl00. The system is equipped with a radiation monitor which is installed so that it indicates the concentration level in the tank on stream. The monitor alarms at the waste panel when the concentration level in the on stream tank reaches a predetermined level. Initiation of the alarm on the waste panel also initiates a general alarm in the Control Room. The gaseous activity in the tanks then decays while the other tanks in the system are being filled with gaseous radioactivity. The maximum activity that can be released as a result of a gas decay tank rupture is the activity stored in one gas decay tank immediately after it has been isolated from the GWPS.

The entire content of a single waste gas decay tank inventory of 200,000 Ci of noble gases (considered as dose equivalent Xe-133) is assumed to be released to the Auxiliary Building, and all of the noble gases are assumed to leak from the building at ground level over a 2 hour period. Based on this model and an onsite 0 to 2 hr atmospheric dilution factor ($1.6x10^{-4}$ sec/m^3), the whole body dose at the nearest point on the exclusion area boundary (EAB) is conservatively calculated to be 0.19 rem. This dose is substantially below the 25 rem whole body value set forth in 10CFR100; it may be concluded that such an incident would not interrupt or restrict public use of areas beyond the EAB.

15.7.2 RADIOACTIVE LIQUID WASTE SYSTEM LEAK OR FAILURE

15.7.2.1 Identification of Causes and Accident Description

The accident is defined as the uncontrolled atmospheric release from the 30,000 gallon floor drain tank due to the postulated rupture of the tank. This tank is the highest potential atmospheric release source term because of its large volume and the fact that it is assumed to be 80 percent full of reactor coolant.

15.7.2.2 Analysis of Effects and Consequences

The activity in the 30,000 gallon floor drain tank, the assumptions on which the activity is based, and the radiological consequences resulting from the release of the activity are discussed in Section 15.7.2.3.

15.7.2.3 Environmental Consequences

This analysis assumes that the plant has been operating with 1 percent failed fuel for an extended period sufficient to achieve equilibrium radioactive concentrations. Floor drain tank III is assumed to contain the inventory as indicated in Table 15.7-3. The entire contents of the tank are assumed to be released to the atmosphere at ground level over a 2 hr period. Other conservative assumptions are detailed in Table 15.7-4.

Based on the foregoing model, the thyroid and whole body doses at the EAB are conservatively calculated to be 2.1 rem and 3.8E-03 rem, respectively. The doses from this accident are substantially below the values set forth in 10CFR100.

15.7.3 POSTULATED RADIOACTIVE RELEASES DUE TO LIQUID TANK FAILURES

The analysis is presented in Section 2.4.12 and 2.4.13.3.

15.7.4 DESIGN BASIS FUEL HANDLING ACCIDENTS

15.7.4.1 Identification of Causes and Accident Description

The accident is defined as dropping of a spent fuel assembly in the Containment Building or spent fuel pool fuel storage area floor resulting in the rupture of the cladding of all the fuel rods in the assembly despite many administrative controls and physical limitations imposed on fuel handling operations. All refueling operations are conducted in accordance with prescribed procedures under the direct surveillance of a supervisor.

15.7.4.2 Analysis of Effects and Consequences

Method of Analysis

The method of analysis used for evaluating the potential radiological consequences of a fuel handling accident is in compliance with Regulatory Guide 1.195.

Fission Product Inventories

The actual fission product gap inventory in the fuel assembly is dependent on the linear heat generation rate of the assembly and the temperature of the fuel. However, the gap inventories assumed in fuel handling accident analyses were based on the conservative guidance contained in Regulatory Guide 1.195. Table 15.7-6 lists the fission product activities released from the damaged fuel rods at the time of the fuel handling accident. These activities are consistent with the assumptions used in analyzing the environmental consequences of postulated fuel handling accidents detailed in Section 15.7.4.3.

Iodine Decontamination Factors

The elemental iodine DF of 400 presented in RG 1.195, is based a fuel depth of 23 ft. and an internal fuel rod pressure of 1200 psig. RG 1.195 states that "If the depth of water is not at least 23 feet, the DF will have to be determined on a case-by-case basis," and "For release pressures greater than 1,200 psig, the iodine DF's will be less than those assumed in this guide and must be calculated on a case-by-case basis using assumptions comparable in conservatism to those of this guide." Since the analysis uses conditions of 1500 psig fuel rod internal pressure and a 21-foot pool depth, a new overall DF that is comparable in conservatism to the RG 1.195 value was calculated. This yields an overall pool decontamination factor of 160 for iodine.

15.7.4.3 Environmental Consequences

15.7.4.3.1 Postulated Fuel Handling Accident Outside Containment

The analysis of a postulated fuel handling accident is performed as follows:

1. The accident is assumed to occur 50 hours after plant shutdown.

2. All of the rods in one fuel assembly are ruptured.

3. The damaged assembly is the highest powered assembly in the core region to be discharged. The values for individual fission product inventories in the damaged assembly are calculated assuming full power operation at the end of core life and a 50 hour shutdown. A radial peaking factor of 1.65 is used.

4. The minimum water depth between the top of the damaged fuel rods and the spent fuel pool surface is 21 ft.

5. All of the gap activity in the rods of the damaged assembly is released to the spent fuel pool. It is assumed that 10% of the fuel in the damaged assembly has an average burnup greater than 54 GWD/MTU and average rod power in excess of 6.3 kW/ft. The gap activity in the 10% of the assembly that exceeds the above limits is 30% for krypton-85,

12% for iodine-131, and 10% for the remaining iodines and noble gases. The gap activity for the remaining 90% of the assembly is 10% for krypton-85, 8% for iodine-131, and 5% for the remaining iodines and noble gases. The gap activities released as a result of this accident are presented in Table 15.7-6.

6. All activity released from the spent fuel pool is released at ground level to the environment over a 2 hour period.

7. The iodine gap inventory is composed of inorganic species (99.75 percent) and organic species (0.25 percent).

8. The overall decontamination factor for the spent fuel pool is 160.

9. No credit is taken for iodine filtration by the primary plant ventilation system.

10. Atmospheric diffusion conditions are assumed to be the 0 to 2 hr ground level case.

The parameters used for this analysis are listed in Table 15.7-7.

Based on the foregoing assumptions, the thyroid and whole body doses at the EAB are conservatively calculated to be 26.0 rem and 0.14 rem, respectively. The corresponding doses at the LPZ are conservatively calculated to be 3.9 rem and 0.021 rem. The calculated doses are within the values set forth in 10CFR100.

15.7.4.3.2 Postulated Fuel Handling Accident Inside Containment

An analysis of the radiological consequences of a fuel handling accident inside the Containment Building would use the same assumptions and yield the same results as those of a fuel handling accident outside the Containment Building. The accident described in the preceding section is considered to represent the limiting case; therefore, no specific analysis of such an accident inside the Containment is provided.

15.7.4.4 Conclusions

The possibility of a fuel handling accident is relatively small due to the many physical, administrative, and safety restrictions imposed on fuel handling operations. However, based on conservative design basis parameters, the calculated doses from a postulated fuel handling accident are well within the values set forth in 10CFR100.

15.7.5 SPENT FUEL CASK DROP ACCIDENTS

The Comanche Peak Nuclear Power Plant Fuel Handling Building overhead crane satisfies NUREG-0554 single-failure-proof requirements and is designed to the requirements of seismic Category I (See Section 3.2). As such it can retain the maximum design load during a Safe Shutdown Earthquake and remain in place under all postulated seismic loadings. The crane is also provided with interlocks which prevent a fuel cask from being lifted more than 29.25 ft above floor elevation or from passing over the new fuel storage area during the spent fuel cask mode of operation (see Section 9.1.2.2). The crane does not pass over the spent fuel pool in any mode of operation. Based on this design approach, the radiological consequences of a spent fuel cask drop accident need not be evaluated.

TABLE 15.7-6
NOBLE GAS AND IODINE ACTIVITIES RELEASED FROM DAMAGED FUEL RODS AS A RESULT OF A FUEL HANDLING ACCIDENT[a]

Nuclide	Curies Released
Kr-83m	1.32E - 2
Kr-85m	5.08E + 0
Kr-88	1.50E - 1
Kr-85	1.16E + 3
Xe-131m	5.08E + 2
Xe-133m	2.18E + 3
Xe-133	8.51E + 4
Xe-135m	7.71E + 1
Xe-135	4.52E + 3
I-131	6.25E + 4
I-132	4.46E + 4
I-133	1.88E + 4
I-135	4.75E + 2

a) Based on the following assumptions:

1. The total gap inventory of one fuel assembly is released to the spent fuel pool.
2. A peaking factor of 1.65 is applied.
3. The accident occurs 50 hours after shutdown.
4. 10% of the rods in the damaged assembly exceed the guidance of RG 1.195, Footnote 7. The Gap activities of the assumed non-compliant 10% of the damaged assembly are 30% for Kr-85, 12% for I-131, and 10% for all other iodines and noble gases. The gap activities for the remaining 90% of the damaged assembly are 10% for Kr-85, 8% for I-131, and 5% for all other iodines and noble gases.

TABLE 15.7-7
PARAMETERS FOR POSTULATED FUEL HANDLING ACCIDENT ANALYSIS

1.	Data and assumptions used to estimate radioactive source from postulated accidents		
	a.	Power level (MWt)	3684

	c.	Damage to fuel assembly	All rods ruptured
	d.	Iodine fractions (inorganic and organic)	Regulatory Guide 1.195
2.	Data and assumptions used to estimate activity released		
	a.	Spent fuel pool decontamination factor	160
	b.	All other pertinent data and assumptions	Regulatory Guide 1.195
3.	Dispersion data		
	a.	EAB and LPZ distances	2080 m and 4 miles
	b.	X/Q	@ EAB 1.6 x 10^{-4} sec/m^3 (0 - 2 hr) @ LPZ 2.4 x 10^{-5} sec/m^3 (0 - 8 hr)
4.	Dose data		
	a.	Method of dose calculation	See Appendix 15B
	b.	Dose conversion assumptions	See Appendix 15B
	c.	Doses	@EAB, thyroid dose = 26.0 rem, whole body dose = 0.14 rem (gamma dose) @ LPZ thyroid dose = 3.9 rem, whole body dose = 0.021 rem (gamma dose)

15.8 ANTICIPATED TRANSIENTS WITHOUT SCRAM

A discussion of Anticipated Transients Without Scram (ATWS) is presented in Reference [1]. The information provided in Reference [1] is applicable to the Comanche Peak Nuclear Power Plant.

ATWS procedures, based on procedures generated by the Westinghouse Owner's Group, were reviewed and incorporated into the CPNPP Emergency Operating Procedures prior to fuel load.

The worst common mode failure which is postulated to occur is the failure to trip the reactor after an anticipated transient has occurred. A series of generic studies [1,2] on ATWS showed acceptable consequences would result provided that the turbine trips and auxiliary feedwater flow is initiated in a timely manner. The effects of ATWS events are not considered as part of the design basis for transients analyzed in Chapter 15. The final NRC ATWS rule [3] required that Westinghouse designed plants install an ATWS Mitigation System Actuation Circuitry (AMSAC) to initiate a turbine trip and actuate auxiliary feedwater flow independent of the Reactor Protection System. The CPNPP AMSAC design is described in Section 7.8.

DELETED

15B DOSE MODELS USED TO EVALUATE THE ENVIRONMENTAL CONSEQUENCES OF ACCIDENTS

15B.1 INTRODUCTION

This section identifies the models used to calculate offsite radiological doses that would result from releases of radioactivity due to various postulated accidents. The postulated accidents are:

1. Steam Line Break
2. Rod Ejection Accident
3. Steam Generator Tube Failure
4. Loss-of-Coolant Accident
5. Radioactive Gas Waste System Leak or Failure
6. Radioactive Liquid Waste System Leak or Failure
7. Design Basis Fuel Handling Accident
8. Primary Coolant Small Line Break Outside Containment
9. Locked Reactor Coolant Pump Rotor

15B.2 ASSUMPTIONS

The following assumptions are basic to the model for the gamma and beta dose due to immersion in a cloud of radioactivity and the model for the thyroid dose due to inhalation of radioactivity.

1. The dose contribution of direct radiation from sources other than the leakage cloud is negligible compared to the dose due to immersion in the leakage cloud.
2. All radioactivity releases are treated as ground level releases regardless of the point of discharge.
3. The dose receptor is a standard man as defined by the International Commission on Radiological Protection (ICRP)[1].
4. Radioactive decay from the point of release to the dose receptor is neglected.
5. Isotopic whole body and beta skin dose conversion factors are taken from references [13] and [14] respectivily.
6. Atmospheric dispersion factors used in the analyses are presented in Section 2.3.

15B.3 GAMMA DOSE

The gamma dose is obtained by considering the dose receptor to be immersed in a radioactive cloud which is infinite in all directions above the ground plane, i.e., a semi-infinite cloud. The concentration of radioactive material within this cloud is taken to be uniform and equal to the maximum centerline ground level concentration that would exist in the cloud at the appropriate distance from the point of release.

The whole body dose is a result of exposure to external gamma radiation. The whole body dose due to immersion in a semi-infinite cloud is given by:

$$D_{\gamma} = K \cdot X/Q \sum_{i}^{A} {}_{Ri} \cdot DCF_{\gamma i} \qquad (15B\text{-}1)$$

where:

D_{γ} is the whole body gamma dose from immersion in a semi-infinite cloud for a given time period, rem.

A_{R_i} is the activity of isotope i released during a given time period, curies

X/Q is the atmospheric dilution factor for a given time period, sec/m3

K is the conversion factor 3.7E12 rem-Bq/Ci-Sv

$DCF_{\gamma i}$ is the whole body gamma dose conversion factor for isotope I, Sv-m^3/Bq-sec

15B.4 THYROID INHALATION DOSE

The thyroid inhalation dose is obtained from the following expression:

$$D_{THY} = K \cdot \chi/Q \cdot B \cdot \sum_{i} Q_{i} \cdot (DCF)_{i} \qquad (15B\text{-}2)$$

where:

D_{THY} = thyroid inhalation dose, rem

X/Q = atmospheric dilution factor for a given time period, sec/m^3

B = breathing rate for a given time period t, m^3/sec

Q_i = total activity of iodine isotope i released in time period t, curies

$(DCF)_i$ = dose conversion factor for iodine isotope i, Sv/Bq inhaled

K is the conversion factor 3.7E12 rem-Bq/Ci-Sv

The thyroid inhalation dose conversion factors and offsite breathing rates used in the above model are given in Table 15B-1.

15B.5 CONTROL ROOM DOSE

The thyroid inhalation, whole body gamma, and beta skin dose models for the major contributors to the Control Room dose are described below. The dose to the Control Room occupants due to a postulated accident is calculated on the basis of source strength, atmospheric transport, dosimetry and Control Room emergency pressurization and filtration considerations as illustrated in the following equations.

The thyroid inhalation dose is obtained from the following expression:

$$D_{THY} = K \cdot \sum_i \sum_j BR \cdot DCF_i \cdot \int_{Tj-1}^{Tj} A_j(t)dt \qquad (15B\text{-}3)$$

where:

i = isotope index

j = time interval index

BR = breathing rate, m^3/sec

DCF_i = dose conversion factor for iodine isotope i, Sv/Bq inhaled

$A_i(t)$ = airborne concentration of iodine isotope i at time t (sec), in the Control Room, curies/m^3

K = is the conversion factor 3.7E12 rem-Bq/Ci-Sv

The thyroid inhalation dose conversion factors and Control Room breathing rate used in the above model are presented in Table 15B-1.

The whole body gamma dose due to inleakage is calculated using the following equation:

$$D_R = K \cdot 1/GF \cdot \sum_i A_i \cdot (DCF)_{\gamma i} \qquad (15B\text{-}4)$$

where:

D_R = Whole body gamma dose, rem

A_i = time integrated concentration of nuclide i, Ci-sec/m^3

K = the conversion factor 3.7E12 rem-Bq/Ci-Sv

GF = Geometry Factor to adjust the dose to reflect the finite cloud in the control room

$(DCF)_{\gamma i}$ = the whole body gamma dose conversion factor for isotope i, Sv-m^3/Bq-sec

$$GF = 1173/V^{0.338} \qquad (15B\text{-}5)$$

V = control room volume, ft^3

The whole body gamma dose conversion factors are presented in Table 15B-1

The beta skin dose due to inleakage is calculated using the following equation:

$$D_B = K \cdot \sum_i A_i \cdot (DCF)_{Bi} \qquad (15B\text{-}6)$$

where:

DB = beta skin dose from immersion in a semi-infinite cloud, rem

A_i = time integrated concentration of nuclide i, Ci-sec/m^3

K = the conversion factor 3.7E12 rem-Bq/Ci-Sv

DCF_{Bi} = the beta skin dose conversion factor for isotope i, Sv-m^3/Bq-sec

The beta skin dose conversion factors are presented in Table 15.B-1.

The whole body gamma dose to Control Room personnel due to a cloud external to the Control Room is calculated using the following equation:

$$D_c = \sum_j \left(X/Q_j \cdot \sum_j A_{ij} \cdot CF \right) \qquad (15B\text{-}7)$$

where:

D_c = whole body gamma dose due to external cloud shine, rem

X/Q_j = atmospheric dispersion factor for the time period j, calculated at the Control Room air intake assuming a ground level release, sec/m3

Ai_j = total activity of nuclide i released during time period j, Ci

CF_i = a dose rate response function for a unit concentration of nuclide i, rem-m^2/Ci-sec.

15B.6 COMPUTER CODES USED IN ACCIDENT ANALYSIS

The computer programs described below may have been used to calculate design-basis source terms and radiological consequences of design basis accidents.

1. RADIOISOTOPE [6]

   Program RADIOISOTOPE calculates the activity of isotopes in a closed system by solving the appropriate simultaneous radioactive decay equations. Based on the activity of any isotope in the system at an initial time, the program calculates the activity of that isotope and its offspring at any later time, provided that the decay scheme is contained in the program library. Furthermore, because gamma activity is important for dose rate and shielding calculations. RADIOISOTOPE also calculates the energy releases in seven gamma energy groups from the decay of an inventory of radionuclides.

2. DRAGON [7]

   Program DRAGON evaluates the activities, dose rates, and time-integrated dose in the reactor building and control room of a nuclear facility or at an adjacent site following release of halogens and noble gases from some control volume. The fission product release to the atmosphere, together with the activities and time-integrated activity concentrations of the halogens which are accumulated in the system, are also computed. Site dose calculations performed by DRAGON employ the semi-infinite cloud models suggested by Regulatory Guide 1.4. The gamma dose in the control room is computed based upon a finite cloud model. Average beta and gamma energies are used in all dose calculations.

3. QADMOD [8]

Program QADMOD calculates dose rates at specified detector locations for a number of different source points representing volumetric sources. The calculational technique employed by this program is commonly referred to as the “point kernel” technique. QADMOD is a modified version of the QAD P-5 program written at Los Alamos Scientific Laboratory by R.E. Malenfant. This modification includes a) the FASTER geometry routines, b) a single point source option, c) a translated cylindrical source volume option, and d) an internal data library which contains flux-to-dose rate conversion factors, buildup factor polynomial coefficients, and mass attenuation coefficients for several materials and compositions.

4. ANISND [9]

   ANISND solves the one-dimensional Boltzmann transport equation for neutrons or gamma rays in rectangular, spherical or cylindrical geometry. The source may be fixed, fission, or a subcritical combination of the two. Criticality search may be performed on any one of several parameters. Cross sections may be weighted using the space and energy dependent flux generated in solving the transport equation. The external cloud dose calculations use Bugle 80, a P-3 cross section library.

5. EFFLMDA [10]

   EFFLMDA calculates the effective spray removal constant as a function of time. The calculation is based on a multi- region model with intermixing among the sprayed and unsprayed regions in a reactor containment.

   The EFFLMDA results are merged with DRAGON input data. This enables the DRAGON program, a single spray region computer code, to simulate a multi-region spray model with step changes in the effective spray constants.

6. RADTRAD [12]

   Program RADTRAD performs similar analysis functions as described above for DRAGON.

16.1 PRELIMINARY TECHNICAL SPECIFICATIONS

This section is not applicable; see Section 16.2 for specific information.

16.2 PROPOSED FINAL TECHNICAL SPECIFICATIONS

16.2.1 DISCUSSION

The previous information included in this Section was removed to facilitate compliance with the Standard Technical Specifications (STS) for Westinghouse Pressurized Water Reactors provided to TXU Electric by the NRC (Reference 1). The format of the STS addresses the categories of the Technical Specifications required by 10CFR50.36. Section 16.2.2 briefly describes the submittal and issuance of Final Technical Specifications for CPSES Units 1 and 2.

16.2.2 FINAL TECHNICAL SPECIFICATION

Final Technical Specifications for CPSES Unit 1 based on Westinghouse Standard Technical Specifications as provided by the NRC (Reference 1) were submitted to the NRC for review and approval. The NRC, by NUREG-1399 (Reference 2) approved CPSES Unit 1 Technical Specifications, as Appendix “A” to the CPSES Unit 1 Operating License.

Final Technical Specifications for CPSES Units 1 and 2, based on Westinghouse Standard Technical Specifications provided by the NRC (Reference 1) were submitted to the NRC for review and approval. The NRC, by NUREG-1468 (Reference 3), approved CPSES Units 1 and 2 Technical Specifications, as Appendix “A” to the CPSES Units 1 and 2 Operating Licenses.

These Technical Specifications are updated periodically by the NRC issuance of License Amendments.

Certain information from the Technical Specifications has been relocated to a separate document titled the CPNPP Technical Requirements Manual (TRM).

Changes to the CPNPP TRM are subject to safety evaluations completed in accordance with the provisions of 10CFR50.59.

Vistra OpCo is submitting this application as Licensee for Comanche Peak Nuclear Power Plant (CPNPP). Vistra OpCo acts as owners agent for construction and operation of CPNPP and is therefore responsible for the design, engineering, procurement, fabrication, and construction technical support of CPNPP. This delegation of authority has been formally established among the Owner. Vistra Operations Company LLC (Vistra OpCo) (operator) and Comanche Peak Power Company LLC (CP PowerCo) (owner) are subsidiaries of Vistra Corp.

To establish and maintain the high quality level required for all quality-related activities for CPNPP, Vistra OpCo has developed a comprehensive Quality Assurance Program (QA Program) as documented in this chapter of the FSAR. Vistra OpCo has implemented those portions of the Quality Assurance Program that are commensurate with the quality activities currently being performed. The program requires, as a minimum, that the quality activities performed by Vistra OpCo and its contractors/vendors comply with the NRC criteria established in 10 CFR Part 50, Appendix B, Licensing of Production and Utilization Facilities, "Quality Assurance Criteria for Nuclear Power Plants". Where appropriate, the requirements of regulatory or safety guides have been incorporated into the program.

The Vistra OpCo Quality Assurance Program requires that a Quality Assurance Manual be established to provide references to the written policies, procedures and instructions used to implement the QA Program for each nuclear power plant project for which it provides service. The combination of the requirements documented in the Quality Assurance Program and the Quality Assurance Manual provides Vistra OpCo with the means of fully executing its assignment.

Appendix 17A identifies all safety-related items for CPNPP within the scope of the Quality Assurance Program.

17.1 QUALITY ASSURANCE DURING DESIGN AND CONSTRUCTION

Section 17.1 has been deleted in its entirety.

17.2 QUALITY ASSURANCE DURING THE OPERATIONS PHASE

17.2.1 ORGANIZATION

17.2.1.1 Organizational Structure

Vistra OpCo, as the licensee, has overall responsibility for the operation of the Comanche Peak Nuclear Power Plant (CPNPP) which includes the Dry Cask Storage System. The Nuclear Generation Group (NG) has been designated by Vistra OpCo to coordinate the design, construction and operation of CPNPP. The organizational structure of Vistra OpCo and the Nuclear Generation Group are described in Section 13.1.

The following paragraphs amplify upon Section 13.1 with regard to establishment and execution of the quality assurance program for the operation of CPNPP. Figure 13.1-2 shows the structure and relationships of those elements of Nuclear Generation Group which function under the control of the QA program. Figure 13.1-3 shows the CPNPP Nuclear Operations organizational structure.

Vistra OpCo may, from time to time, assign responsibility for executing certain portions of the program to qualified consultants and contractors. However, Vistra OpCo retains ultimate responsibility for the CPNPP operations quality assurance program.

The reference to Dry Cask Storage System in this document includes the Independent Spent Fuel Storage Installation (ISFSI) facility, activities supporting spent fuel dry cask loading, and the associated dry cask storage equipment.

17.2.1.1.1 Senior Vice President & Chief Nuclear Officer

The Senior Vice President & Chief Nuclear Officer is responsible for the overall management of Nuclear Generation operations, including operation of CPNPP, and for the establishment of company policies related to Nuclear Generation. He has the overall responsibility for the establishment and execution of the quality assurance program for the operation of CPNPP.

The Senior Vice President & Chief Nuclear Officer has assigned to the Site Vice President the overall responsibility for operation of CPNPP and for implementation of the quality assurance program for the Nuclear Operations function at CPNPP.

The Senior Vice President & Chief Nuclear Officer has assigned to the Senior Director, Engineering & Regulatory Affairs the overall responsibility for engineering and support of CPNPP, and for implementation of the quality assurance program for the Nuclear Engineering function at CPNPP.

17.2.1.1.2 Site Vice President

The Site Vice President is responsible to the Senior Vice President & Chief Nuclear Officer for plant operations at CPNPP.

Specific duties and responsibilities of the Site Vice President include the following:

1. Technical and administrative direction of the Director, Organizational Effectiveness

2. Technical and administrative direction of the Director, Nuclear Training.

3. Operational and technical support of CPNPP.

4. Technical and administrative direction for the implementation of quality assurance requirements and controls at CPNPP.

5. Technical and administrative direction of Plant Manager and assumes duties if the position is not occupied.

17.2.1.1.3 Plant Manager

The Plant Manager is responsible to the Site Vice President for plant operations at CPNPP.

Specific duties and responsibilities of the Plant Manager include the following:

1. Technical and administrative direction of the direct reports shown in Figure 13.1-3.

2. Operational and maintenance support of CPNPP.

3. Manager of all operations activities at CPNPP.

4. Chairmanship of the Station Operations Review Committee (SORC).

5. Membership on the Operations Review Committee upon appointment by the Senior Vice President & Chief Nuclear Officer.

17.2.1.1.3.1 Station Operations Review Committee (SORC)

The SORC shall function to advise the Plant Manager on all matters related to nuclear safety.

The SORC shall as a minimum be composed of the Chairman and six individuals who collectively have experience and expertise in the areas listed below and meet the requirements of Regulatory Guide (RG) 1.8, Rev. 2 for required experience.

Operations

Maintenance

Instrumentation and Controls

Technical Support

Radiation Protection

Quality Assurance

The Plant Manager shall serve as the chairman of SORC. A senior health physicist is acceptable for the Radiation Protection representative on SORC. The SORC members shall be designated, in writing, by the Plant Manager.

All alternate members shall be appointed in writing by the Plant Manager to serve on a temporary basis; however, no more that two alternates shall participate as voting members in SORC activities at any one time.

The SORC shall meet periodically as determined by the SORC Chairman or the designated alternate.

The quorum of the SORC necessary for the performance of the SORC responsibility and authority shall consist of the Chairman or his designated alternate and a majority of the regular members (or their alternates).

The SORC shall be responsible for:

1. Review of applicable administrative procedures recommended in Appendix A of Regulatory Guide 1.33, Revision 2, February 1978.

2. Review of: (1) procedures, (2) change to procedures, equipment, systems or facilities, and (3) tests or experiments where nuclear safety is adversely affected;

3. Review of proposed procedures and changes to procedures, equipment, systems or facilities which require an amendment to the operating license;

4. Review of proposed test or experiments which require an amendment to the operating license;

5. Review of proposed changes to Technical Specifications or the Operating License:

6. Investigation of all violations of the Technical Specifications requiring a written report to the NRC, including the forwarding of reports covering evaluation and recommendations to prevent recurrence to the Senior Vice President & Chief Nuclear Officer and to the ORC:

7. Review of reports or operating abnormalities, deviations from expected performance of plant equipment and of unanticipated deficiencies in the design or operation of structures, systems or components that affect nuclear safety;

8. Review of all events submitted pursuant to 10CFR50.73. Other nonroutine reports may be reviewed at the discretion of the SORC Chairman or the responsible manager.

9. Review of changes to the PROCESS CONTROL PROGRAM, the OFFSITE DOSE CALCULATION MANUAL, and Radwaste Treatment Systems;

10. Review of any accidental, unplanned or uncontrolled radioactive release including the preparation of reports covering evaluation, recommendations, and dispositions of the corrective action to prevent recurrence and the forwarding of these reports to the Senior Vice President & Chief Nuclear Officer and to the ORC;

11. Review of Unit operations to detect potential hazards to nuclear safety;

12. Investigations or analysis of special subjects as requested by the Chairman of the ORC or the Plant Manager.

13. Review of the Fire Protection Report and implementing procedures and submittal of recommended Fire Protection Report changes to the ORC; and

14. Review of the Technical Requirements Manual and revision thereto.

17.2.1.1.3.1.1 The SORC shall:

1. Recommend in writing to the designated manager (see Section 17.2.1.6) approval or disapproval of items considered under items 1 through 5 above. prior to their implementation; and

2. Provide written notification within 24 hours to the Senior Vice President & Chief Nuclear Officer, and the Operations Review Committee of disagreement between the SORC and the designated manager (see Section 17.2.1.6) however, the Plant Manager shall have responsibility for resolution of such disagreements pursuant to Technical Specification 5.1.1.

The SORC shall maintain written minutes of each SORC meeting that, at a minimum, document the results of all SORC activities performed under the responsibility provisions above. Copies shall be provided to the Senior Vice President & Chief Nuclear Officer and the Operations Review Committee.

Any changes in the conduct of operation of the SORC will be made with the approval of the Plant Manager. Changes in the organization of the SORC will be made with the approval of the Plant Manager.

17.2.1.1.4 Director, Nuclear Oversight

The Director, Nuclear Oversight reports directly to the Senior Vice President & Chief Nuclear Officer and is responsible for assuring effective implementation of the Quality Assurance Program. This reporting relationship assures that the Director, Nuclear Oversight has sufficient authority, organizational freedom, and independence from undue influence from, or responsibility for, costs and schedules such that the Director, Nuclear Oversight can effectively assure implementation of and compliance with the CPNPP operations quality assurance requirements and controls.

The Director, Nuclear Oversight communicates directly with the Nuclear Generation Group supervisory and management personnel and with appropriate management levels in consultant and contractor quality assurance organizations to identify quality problems; initiate, recommend or provide solutions; and to verify implementation of solutions to quality problems. The Director, Nuclear Oversight also has authority to “stop work” during the operations phase.

Specific duties and responsibilities of the Director, Nuclear Oversight include the following:

1. Providing technical services and management in areas of Nuclear Oversight including quality assurance/quality control

2. Membership on the Operations Review Committee upon appointment by the Senior Vice President & Chief Nuclear Officer.

Specific duties and responsibilities of the Director, Nuclear Oversight include the following:

1. Technical and administrative direction of Nuclear Oversight personnel.

2. Verification through evaluations that procedures for the control of quality-related activities comply with quality assurance requirements.

3. Verification through evaluations of the implementation of the quality assurance program within the Nuclear Generation Group and evaluation of its effectiveness.

4. Assurance through evaluation and inspection that consultants, contractors and suppliers providing quality-related items or services have established and implemented an adequate quality assurance program.

5. Responsible for submitting the Quality Assurance Manual for concurrence and approval to the Senior Vice President & Chief Nuclear Officer.

17.2.1.1.5 Senior Director, Engineering & Regulatory Affairs

The Senior Director, Engineering & Regulatory Affairs is responsible for providing engineering related technical services in support of CPNPP operations.

Specific duties and responsibilities of the Senior Director, Engineering & Regulatory Affairs include the following:

1. Technical support to Nuclear operations.

2. Technical direction and administrative guidance to engineering staff.

3. Assistance, as required, in the procurement of equipment, materials, and services for the operation, maintenance or modification of CPNPP.

17.2.1.2 Nuclear Oversight

Nuclear Oversight, under the direction of the Director, Nuclear Oversight functions to assure effective implementation of the quality assurance program.

Nuclear Oversight has sufficient authority and organizational freedom at CPNPP to identify quality problems, recommend solutions, verify implementation of solutions, to stop unsatisfactory work and control further processing, delivery or installation of nonconforming material until proper disposition has occurred.

The Director, Nuclear Oversight advises the Senior Vice President & Chief Nuclear Officer of the status of the quality assurance program at CPNPP and of any significant conditions which are adverse to quality.

Specific functions performed by Nuclear Oversight include:

1. Quality assurance evaluations of Nuclear Generation quality-related activities, both offsite and onsite.

2. Evaluation of consultants', contractors', and suppliers' quality assurance programs and implementing procedures.

3. Evaluations and inspections conducted at equipment and material suppliers' facilities.

4. Review of procurement documents to assure incorporation of adequate quality assurance requirements for procured items and services.

5. Evaluations and inspections of site quality related activities to assure compliance with the applicable quality requirements.

6. Engineering services to support the Operations Review Committee (ORC).

7. Health Physics review of programs necessary for radiological protection of Company personnel and property, the environment and the general public.

8. Support the development of appropriate emergency plans for Vistra OpCo in accordance with regulatory guidelines and requirements and performance of the 10CFR50.54(t) independent review of the Emergency Planning Program.

9. Other independent verification/review responsibilities as described in Section 13.1.1.2.4 for Director, Nuclear Oversight.

10. Proposed changes to Technical Specifications or the Operating License;

17.2.1.3 Operations Review Committee

Independent reviews of activities affecting plant safety during the operations phase are performed by the Operations Review Committee.

The ORC shall function to provide independent review of designated activities in the areas of:

1. Nuclear power plant operations,

2. Nuclear engineering,

3. Chemistry and radiochemistry,

4. Metallurgy,

5. Nondestructive testing,

6. Instrumentation and control,

7. Radiological safety,

8. Mechanical and electrical engineering,

9. Administrative controls and quality assurance practices, and

10. Other appropriate fields associated with the unique characteristics of CPNPP.

The ORC shall report to and advise the Senior Vice President & Chief Nuclear Officer on those areas of responsibility specified in Section 17.2.1.3. ORC members should report all matters adversely affecting nuclear safety to the Senior Vice President & Chief Nuclear Officer (via the ORC Chairman) upon identification.

The ORC shall be composed of at least five individuals of whom no more than a minority are members of the CPNPP nuclear operations staff. The Chairman and all members will be appointed by the Senior Vice President & Chief Nuclear Officer.

The ORC Chairman shall hold a bachelor's degree in an engineering or physical science field or equivalent experience and a minimum of 6 years technical managerial experience.

The ORC members shall hold a bachelor's degree in an engineering or physical science field or equivalent experience and a minimum of 5 years technical experience. It is the responsibility of the Chairman to ensure experience and competence is available to review problems in areas listed in items 1 through 9 above. To a large measure, this experience and competence rests with the membership of the ORC. In specialized areas, this experience may be provided by personnel who act as consultants to the ORC.

The alternate for the Chairman and all alternate members shall be appointed in writing by the Senior Vice President & Chief Nuclear Officer to serve on a temporary basis.

Consultants shall be utilized as determined by the Chairman, to provide expert advice to the ORC.

The ORC shall meet not less than twice per year.

The quorum for formal meetings shall consist of not less than a majority of the principals, or duly appointed alternates, and shall be subject to the following constraints: the Chairman or his designated alternate shall be present for all formal meetings and no more than a minority of the quorum shall be members of the CPNPP nuclear operations staff. The Chairman or his alternate (if a member of ORC) will be included in the overall quorum count.

17.2.1.3.1 ORC Reviews

The ORC shall be responsible for the review of:

1. The 10CFR50.59 evaluations for: (1) changes to procedures, equipment, or systems; and (2) tests or experiments.

2. Violations of codes, regulations, orders, Technical Specifications, license requirements, or of internal procedures or instructions having nuclear safety significance;

3. Significant operating abnormalities or deviations from normal and expected performance of unit equipment that affect nuclear safety;

4. All events submitted pursuant to 10CFR50.73;

5. All recognized indications of an unanticipated deficiency in some aspect of design or operation of structures, systems, or components that could affect nuclear safety; and

6. Reports and meeting minutes of the SORC.

7. ORC shall perform periodic reviews of the audit program, including the audits discussed in 17.2.18.

17.2.1.3.2 ORC Records

Records of ORC activities shall be prepared, approved and distributed as indicated below:

1. Minutes of each ORC meeting shall be prepared, approved and forwarded to the Senior Vice President & Chief Nuclear Officer within 30 days following each meeting. Meeting minutes will be promptly distributed to appropriate members of management;

2. Reports of reviews encompassed by Section 17.2.1.3.1 shall be prepared, approved and forwarded to the Senior Vice President & Chief Nuclear Officer within 30 days following completion of the review.

17.2.1.4 Delegation of Nuclear Oversight Functions

Nuclear Generation (NG) periodically retains qualified consultants and contractors to provide safety-related services. All consultants and contractors providing safety-related services and suppliers providing safety-related equipment or materials for CPNPP are required to establish and implement quality assurance programs appropriate for their scope of supply. NG includes specific requirements in procurement documents with which consultants', contractors', or suppliers' quality assurance programs must comply.

17.2.1.5 Personnel Qualifications

17.2.1.5.1 Director, Nuclear Oversight

The following minimum qualification requirements have been established for the Director, Nuclear Oversight:

1. Engineering or related science degree;

2. Minimum of four years of related experience including two years of nuclear power plant experience, one year of supervisory or management experience, and one year of the experience is in performing quality verification activities.

3. Special requirements shall include management and supervisory skills and experience or training in leadership, interpersonal communication, management responsibilities, motivation of personnel, problem analysis and decision making, and administrative policies and procedures.

Individuals who do not possess these formal education and minimum experience requirements should not be eliminated automatically when other factors provide sufficient demonstration of

their abilities. These other factors are evaluated on a case-by-case basis and approved and documented by senior management.

17.2.1.6 Independent Technical Review and Controls

Activities which affect nuclear safety shall be conducted as follows:

1. Procedures required by Technical Specification 5.4 and other procedures which affect plant nuclear safety, and changes thereto, shall be prepared, reviewed and approved. Each such procedure or procedure change shall be reviewed by a qualified individual/ group other than the individual/group which prepared the procedure or procedure change, but who may be from the same organization as the individual/group which prepared the procedure or procedure change. The Plant Manager shall designate approval authority for station procedures. Changes to procedures which do not change the intent of approved procedures may be approved for implementation by two members of the Nuclear Operations Management Staff, at least one of whom holds a Senior Operation License, provided such approval is prior to implementation and is documented. Such changes will be approved by the original approval authority within 14 days of implementation.

2. Proposed tests and experiments which affect plant nuclear safety shall be prepared, reviewed and approved. Each such test or experiment shall be reviewed by a qualified individual/group other than the individual/group which prepared the proposed test or experiment. Proposed test and experiments shall be approved before implementation by the Plant Manager. Individuals responsible for conducting such reviews shall be members of the Nuclear Operations Management Staff previously designated by the Plant Manager.

3. Proposed changes to Technical Specifications or Operating License. Each such change shall be reviewed by a qualified individual/group meeting the experience requirements of Regulatory Guide 1.8 revision 2, 1987 other than the individual/group which proposed the change.

4. Proposed changes, or modifications to plant nuclear safety-related structures, systems and components shall be reviewed as designated by the Senior Director, Engineering & Regulatory Affairs. Each such modification shall be reviewed by a qualified individual/ group meeting the experience requirements of ANSI N18.1-1971 Section 4.6 other than the individual/group which designed the modification, but who may be from the same organization as the individual/group which designed the modifications. Individuals/groups responsible for conducting such reviews shall be previously designed by the Senior Director, Engineering & Regulatory Affairs. Proposed modifications to plant nuclear safety-related structures, systems, and components shall be approved by the Plant Manager prior to implementation.

5. Individuals responsible for reviews performed in accordance with the requirements of items 1 and 2 above, shall be members of the Nuclear Operations Management staff previously designated by the Plant Manager. Each such review shall include a determination of whether or not additional cross-disciplinary review is necessary. If deemed necessary, such review shall be done in accordance with the appropriate qualification requirements; and

6. Each review shall include a determination of whether or not an amendment to the operating license is required. For items requiring an amendment to the operating license, NRC approval shall be obtained prior to the Plant Manager approval for implementation.

Records of the activities described above shall be provided to the Plant Manager, SORC, and/or ORC as necessary for the required reviews.

17.2.1.6.1 Reportable Events

The following action shall be taken for all events submitted pursuant to 10CFR50.73:

Each event shall be reviewed by the SORC, and the results of this review shall be submitted to the ORC and the Senior Vice President & Chief Nuclear Officer.

Written procedures shall be established, implemented and maintained covering the Process Control Program implementation.

Changes to the PCP:

1. Shall be documented and records of reviews performed shall be retained as required by FSAR Section 17.2.17.1. This documentation shall contain:

   a. Sufficient information to support the change together with the appropriate analyses or evaluations justifying the change(s) and

   b. A determination that the change will maintain the overall conformance of the solidified waste product to existing requirements of Federal, State, or other applicable regulations.

2. Shall become effective after review and acceptance by the SORC and the approval of the Plant Manager.

Each procedure and administrative policy of Technical Specification 5.4.1 and changes thereto, shall be reviewed and approved prior to implementation as set forth above.

17.2.2 QUALITY ASSURANCE PROGRAM

The Quality Assurance Program requires a Quality Assurance manual be developed for each nuclear power plant, which prescribe specific measures to assure the quality of safety-related activities, structures, systems and components of that facility. The quality assurance requirements and controls implemented during operations of CPNPP are established by the portion of the CPNPP Quality Assurance Program in this section (17.2) of the FSAR. Quality assurance requirements and controls established by the CPNPP Quality Assurance Program for the Dry Cask Storage System shall be implemented throughout the period during which the ISFSI is licensed or the spent fuel storage cask is certified.

Quality assurance requirements and controls are established and implemented throughout the testing and operation phases at CPNPP. This program shall be implemented at least 90 days prior to fuel loading. Responsibilities and authority, and measures for the control and accomplishment of activities affecting the quality and operation of safety-related structures,

systems, and components of CPNPP are defined. The structures, systems, and components covered by the quality assurance program are discussed in Appendix 17A. These provisions apply to all activities, such as operating, maintaining, repairing, modifying, and refueling which affect the safety-related functions of those structures, systems, and components. These provisions, as necessary, shall ensure conformance with the approved design of the ISFSI or spent fuel storage cask.

A Quality Assurance Program shall be developed and implemented to attain high levels of quality assurance during the operation of CPNPP. This program shall comply with the requirements of Title 10, Code of Federal Regulations, Part 50, Appendix B, "Quality Assurance Criteria for Nuclear Power Plants and Fuel Processing Plants," and certain NRC Regulatory Guides and ANSI standards as identified in the Final Safety Analysis Report (FSAR).

The Quality Assurance Program also complies with the requirements of Title 10, Code of Federal Regulations, Part 72, Subpart G, "Quality Assurance Requirements for the Independent Storage of Spent Nuclear Fuel, High Level Radioactive Waste, and Reactor-Related Greater Than Class C Waste". Appendix 17A addresses the applicability of the quality assurance program requirements and procedural controls for the Dry Cask Storage System shall be based on the following considerations concerning the complexity and proposed use of the structures, systems, or components:

1. The impact of malfunction or failure of the item on safety;

2. The design and fabrication complexity or uniqueness of the item;

3. The need for special controls and surveillance over processes and equipment;

4. The degree to which functional compliance can be demonstrated by inspection or test; and

5. The quality history and degree of standardization of the item.

Vistra OpCo may delegate to others such as contractors, agents, or consultants the work of establishing and executing the quality assurance program, or any part thereof, but the overall responsibility for the Quality Assurance (QA) Program lies with the Senior Vice President & Chief Nuclear Officer. Specific responsibility for development and administration of the program rests with the Director, Nuclear Oversight. The Senior Vice President & Chief Nuclear Officer will assure that a biennial independent assessment of the evaluation program is performed.

These independent assessments will be conducted in accordance with predetermined schedules, with results documented, and a follow-up system utilized to assure that corrective action is taken and evaluated when it is considered necessary to verify implementation requirements of 10CFR50, Appendix B and 10CFR72 Subpart G, as applicable. The Vice-Presidents shall meet periodically to assess the status and adequacy of the quality assurance program.

The quality assurance requirements and controls applicable to the operations phase, comply with the requirements of 10 CFR Part 50, Appendix B. Table 17.2-1 provides a matrix showing those sections of the QA Manual which satisfy the requirements of each criterion of 10 CFR Part 50, Appendix B. The quality assurance requirements and controls shall be consistent with the

applicable guidance of those Regulatory Guides and industry standards listed in Table 17.2-2 and discussed in Appendix 1A(B).

The quality assurance requirements and controls are designed to assure that activities affecting the quality and operation of safety-related items are accomplished in a planned and controlled manner. Activities affecting quality are accomplished in accordance with written, approved procedures and instructions under suitably controlled conditions. Controlled conditions include, as applicable, appropriate equipment, suitable environmental conditions, and completion of prerequisites. All procedures prescribing activities affecting quality are controlled and distributed in accordance with the measures described in Section 17.2.6.

The Director, Nuclear Oversight is responsible for assuring, through surveillance and audit, implementation of the Quality Assurance Program. He is responsible for regularly assessing the status and adequacy of the Program, within the Nuclear Generation Group, and as implemented by consultants, contractors, and suppliers. The Director, Nuclear Oversight reports the results of these evaluations to the Senior Vice President & Chief Nuclear Officer. Unresolved issues between the Director, Nuclear Oversight and others concerning quality are brought to the Senior Vice President & Chief Nuclear Officer for resolution.

The Director, Nuclear Oversight has overall responsibility for the identification, scheduling, assignment, conduct and reporting of station activities assigned to the Nuclear Oversight. Station activities affecting quality are subject to quality surveillance and audit by Nuclear Oversight personnel.

In addition, the Director, Nuclear Oversight has responsibility for administration and implementation of the CPNPP quality control program.

The Director, Nuclear Oversight reviews procedures during the operations phase for quality assurance requirements either as a normal function of the Station Operations Review Committee, or as described in section 17.2.6. Procedural implementation of quality requirements is periodically reviewed by the Nuclear Oversight organization through evaluation activities.

An indoctrination and training program is established for those personnel performing activities affecting quality. The scope, objectives, and methods for implementing the indoctrination and training program are prescribed by written, approved procedures. These procedures also prescribe methods for documenting the accomplishment of training. The indoctrination and training program includes provisions that personnel performing activities affecting quality are:

1. Instructed as to the purpose, scope, and implementation of the Quality Assurance Program and related procedures and instructions as appropriate to their activities.

2. Qualified in the principles and techniques of activities for which they are responsible.

3. Retrained, re-examined or recertified, when appropriate, to maintain necessary proficiency in those activities for which they are responsible.

17.2.3 DESIGN CONTROL

Requirements for the control of design activities associated with modifications (involving a new design or change in existing design) of safety-related structures, systems, and components are

consistent with the provisions of Regulatory Guide 1.33, and Regulatory Guide 1.64 as discussed in Appendix 1A(B).

The Plant Manager, or his designee, shall have the responsibility for approving and controlling the implementation of station design modifications. The Senior Director, Engineering & Regulatory Affairs shall have the overall responsibility for developing procedures to maintain and control the design control process.

The SORC will submit all proposed station design modifications which involve a change in CPNPP Technical Specifications or other changes to the operating license to the ORC for review. 10CFR50.59 evaluations on station design modifications which do not require a license amendment or a change in CPNPP Technical Specifications will be reviewed by ORC, however, this will not be a prerequisite for implementation. The Plant Manager, or his designee, approves each station design modification for implementation.

10CFR72.48 establishes the conditions under which an Independent Spent Fuel Storage Installation (ISFSI) licensee or a spent fuel storage cask certificate holder may make changes in the ISFSI facility or spent fuel storage cask design without prior NRC approval. Changes in the conditions specified in the license or Certificate of Compliance (CoC) require prior NRC approval. When changes occur that affect the Dry Cask Storage System structures, systems, and components, review and approval of the change must consider the requirements of 10CFR72.48.

All design modification requests made by station personnel shall be submitted to the Senior Director, Engineering & Regulatory Affairs for coordination of the station level engineering review. The actual change of design for those design modification requests approved by the Plant Manager may be done by Nuclear Engineering personnel or approved engineering services contractors. The above organizations will have approved design procedures and/or instructions before any design modifications are performed by the respective organization. These procedures and/or instructions will assure proper design review and verification. These procedures and instructions will also assure that design control is commensurate with the original design. The Senior Director, Engineering & Regulatory Affairs will assure that the designer is provided with the latest revisions to all drawings, specifications, and other design documents which are applicable.

Design changes, including those originating on site, are subject to the same controls which were applicable to the original design. The Senior Director, Engineering & Regulatory Affairs may designate an organization to make design changes other than the one which prepared the original design. In these cases, the Senior Director, Engineering & Regulatory Affairs will assure that organization has access to pertinent background information, including an adequate understanding of the requirements and intent of the original design, and has demonstrated competence in applicable design areas.

The Senior Director, Engineering & Regulatory Affairs shall coordinate necessary revisions to drawings and other design documents. The Plant Manager shall coordinate necessary revisions to plant procedures and instructions as a result of design changes. Changes are promptly distributed to ensure availability to responsible plant personnel prior to commencement of work and replacement; and delineation of acceptance criteria for inspection and tests. In addition, the above controls are applied as necessary to the Dry Cask Storage System for shielding and features that facilitate documentation.

17.2.3.1 Design Changes

Design changes made to the facility are accomplished in a planned and controlled manner in accordance with written, approved procedures. These procedures include provisions, as necessary, to ensure that:

1. Design documents, specifications, drawings, and procedures and instructions reflect applicable regulatory requirements and design bases.

2. Design documents specify quality requirements or reference quality standards as necessary.

3. There is adequate review of the suitability of materials, parts, components, and processes which are essential to the safety- related functions of structures, systems, and components.

4. Materials, parts, and components which are standard commercial (off the shelf) or which have been previously approved for a different application are evaluated for suitability prior to selection.

5. Design documents are revised to reflect design modifications.

6. Internal and external design interfaces between organizations participating in design modifications are adequately controlled, including the review, approval, release, and distribution of design documents and revisions.

The above controls are applied as necessary to such aspects of design as reactor physics; seismic, stress, thermal, hydraulic, radiation, and accident analyses; compatibility of materials; and accessibility for inservice inspection, maintenance, repair and replacement; and delineation of acceptance criteria for inspections and tests. In addition, the above controls are applied as necessary to the Dry Cask Storage System for shielding and features that facilitate decontamination.

17.2.3.1.1 Design Change Verification

The adequacy of design changes shall be verified by the performance of design reviews, alternate calculations, or qualification testing. The control measures specified in the plan for control of design verification activities are as follows:

1. Personnel responsible for design verification do not include the original designer or the designer’s immediate supervisor.

2. Written procedures identify the positions or organizations responsible for design verification and define their authority and responsibility.

3. Qualification tests to verify the adequacy of the design are performed using the most adverse specified design conditions.

4. Design changes are reviewed to assure that design parameters are defined and that inspection and test criteria are identified.

Any errors or deficiencies found in the design process or the design itself are documented and corrective action taken, as described in Section 17.2.16.

Design documents and revisions thereto are controlled and distributed as described in Section 17.2.6. Records of design activities and design changes are collected, stored, and maintained, as described in Section 17.2.17.

17.2.4 PROCUREMENT DOCUMENT CONTROL

Requirements are established for the control of procurement documents prepared by NP, or their designated agents for safety-related components, materials, and services. These requirements are consistent with the provisions of Regulatory Guide 1.33 and Regulatory Guide 1.123 as discussed in Appendix 1A(B) and apply to procurement documents prepared by NP, or their designated agents.

Procurement documents, such as purchase specifications, contain or reference the following:

1. The design basis technical requirements, including the applicable regulatory requirements, material and component identification requirements, drawings, specifications, codes and industrial standards, and test and inspection requirements, including inspection hold points.

2. The applicable requirements of 10 CFR Part 50, Appendix B and of the QA Program, which must be complied with and described in the supplier's QA program; or, identification and verification of characteristics critical to the safety function of the procured item to provide reasonable assurance that the item will perform its intended safety related function.

   The applicable requirements of 10CFR72, Subpart G are imposed in procurement documents for Dry Cask Storage System items and services as required by Appendix 17A.

   When purchasing commercial grade calibration services from a calibration laboratory accredited by National Voluntary Laboratory Accreditation Program (NVLAP) or American Association for Laboratory Accreditation (A2LA), the procurement documents are not required to impose a quality assurance program consistent with the requirements of 10CR50 Appendix B or identification and verification of characteristics critical to the safety function provided each of the following conditions are met:

   a. The procurement documents impose any additional technical and administrative requirements, as necessary, to comply with NP's QA program and technical provisions. The procurement document shall require that the calibration certificate/report include identification of the laboratory equipment/standard used.

   b. The procurement documents require reporting as-found calibration data when calibrated items are found to be out-of-tolerance.

   c. A documented review of the supplier's accreditation has been performed as discussed in Section 17.2.7.

3. Identification of the documentation to be prepared, maintained, or submitted (as applicable) to NP for review and approval. These documents may include, as necessary, inspection and test records, qualification records, or code required documentation.

4. Identification of those records to be retained, controlled, and maintained by the supplier, and those delivered to the purchaser prior to use or installation of the hardware.

5. NP's right of access to supplier's facilities and records for source inspection and evaluation.

6. Requirements for supplier reporting and dispositioning of nonconformances from procurement requirements.

7. Provisions for extending applicable requirements of the procurement documents to lower-tier suppliers.

NP procurement documents are prepared, reviewed, approved, and controlled in accordance with written procedures which clearly delineate the sequence of actions to be accomplished and which identify the individuals or groups responsible for accomplishing those actions. These procedures include provisions for review of procurement documents. This review is performed to insure that necessary quality requirements are incorporated and correct, and that procurement requirements for spare or replacement parts are equivalent to or better than those used for the original equipment. Documentary evidence of that review and approval is retained and available for verification. Changes to purchase documents are subject to the same degree of control as that utilized in the preparation of the original documents.

NP evaluates supplier quality assurance programs prior to award of contracts or issuance of purchase orders, as discussed in Section 17.2.7.

17.2.5 INSTRUCTIONS, PROCEDURES, AND DRAWINGS

Activities affecting the quality of safety-related structures, systems, and components be prescribed by and accomplished in accordance with documented instructions, procedures, and drawings. The manager or supervisor who has cognizance over a specific safety-related activity is responsible for the development and approval of procedures and instructions for prescribing the accomplishment of that activity. Administrative procedures and instructions are reviewed and approved prior to performance of the activity. The cognizant supervisor is responsible for ensuring that the activity is performed in accordance with the procedures and instructions. The development, review, and use of procedures, instructions, and drawings is reviewed on a periodic basis by Nuclear Oversight personnel as part of the station surveillance and audit program. These requirements are consistent with the provisions of Regulatory Guides 1.33, 1.30, and 1.116 as discussed in Appendix 1A(B).

Requirements regarding the content of various types of instructions and procedures are established which provide for the inclusion, as necessary, of items such as prerequisites, precautions, qualitative or quantitative acceptance criteria, inspection points, and checklists, depending upon the nature of the instruction or procedure.

Administrative procedures clearly delineate the sequence of actions to be accomplished in the preparation, review, approval, and control of those instructions and procedures, and they identify the individuals responsible for those actions.

Confirmation that these instructions and procedures meet requirements of the QA Program and are properly implemented is accomplished through audit activities by Nuclear Oversight.

17.2.6 DOCUMENT CONTROL

Requirements are established for the control of documents that prescribe activities affecting quality. The documents which are to be controlled include:

1. Design Specifications

2. Design, manufacturing, construction, and installation drawings

3. Procurement documents

4. The QA Manual and all station procedures and instructions which implement requirements of the QA Program.

5. Maintenance, modification, and operating procedures and instructions

6. Final Safety Analysis Report

7. Inspection and test procedures and instructions

17.2.6.1 Design Control Requirements

These requirements are consistent with the provisions of Regulatory Guide 1.33 as discussed in Appendix 1A(B) and include the following measures:

1. Documents, and changes thereto, are reviewed for adequacy and approved for release by authorized personnel in accordance with written procedures. These procedures identify those individuals or groups responsible for reviewing, approving, and issuing documents and revisions thereto. These reviews include as appropriate a review for QA-related aspects by Quality Assurance or an individual other than the person who generated the documents but qualified in quality assurance.

2. Documents, and changes thereto, are promptly distributed to ensure availability prior to commencement of work.

3. Changes to documents are reviewed and approved by the same organization that performed the original review and approval unless another qualified organization is designated.

4. Master status lists identifying the current revision of documents are periodically updated and utilized to preclude the use of superseded documents.

5. Obsolete or superseded documents are destroyed or identified to prevent their inadvertent use.

6. Documents generated by NP are controlled in accordance with written, approved procedures and instructions. Maintenance, modification and inspection procedures and instructions affecting safety related equipment are reviewed by a person knowledgeable in QA disciplines to determine:

   a. The need for inspection, identification of inspection personnel, and documentation of inspection results.

   b. That the necessary inspection requirements, methods, and acceptance criteria have been identified.

The Director, Nuclear Oversight is responsible for providing the necessary reviews of these procedures and instructions.

17.2.7 CONTROL OF PURCHASED MATERIAL, EQUIPMENT AND SERVICES

Requirements are established for the control of purchased safety-related material, equipment and services, including spare or replacement parts. These requirements are consistent with the provisions of Regulatory Guides 1.33, 1.38, 1.123, and 1.144 as discussed in Appendix 1A(B).

Measures have been established in procedures which determine the level of quality assurance required for the procurement of an item or service. As required, contractor and suppliers are evaluated by Nuclear Oversight personnel prior to award of a purchase order or contract to assure the contractor's or supplier's capability to comply with procurement document requirements. This evaluation is based on one or more of the following:

1. A review of the supplier's quality assurance program description provided with the proposal/bid.

2. A review of historical evidence of the supplier's performance in providing similar items or services.

3. A preaward survey of the supplier's facilities and QA program.

Technical requirements for items and materials to be procured are developed by the design or engineering organization responsible for the modification or maintenance activity. Procurement documents for safety related items and materials are reviewed for inclusion of technical and quality assurance requirements by inspection personnel prior to acceptance of the procured item or material. The results of the Nuclear Oversight review are documented and retained for future reference.

Evaluation and inspection of suppliers and contractors, are conducted where appropriate, to assure compliance with quality requirements. Nuclear Oversight is responsible for evaluation and inspection of offsite suppliers and contractors and for evaluation of contractors providing services onsite. Evaluation of suppliers and contractors is performed by qualified personnel in accordance with written procedures, instructions and checklists.

When purchasing commercial grade calibration services from a calibration laboratory, source evaluation and inspection of these suppliers need not be performed provided each of the following conditions are met:

1. The procurement documents impose any additional technical and administrative requirements, as necessary, to comply with the NP's QA program and technical provisions. The procurement document shall require the calibration certificate/report to include identification of the laboratory equipment/standard used.

2. The procurement documents require reporting as-found calibration data when calibrated items are found to be out-of-tolerance.

3. A documented review of the supplier's accreditation shall be performed and shall include a verification of each of the following:

    - The calibration laboratory holds accreditation by the National Voluntary Laboratory Accreditation Program (NVLAP) or by the American Association for Laboratory Accreditation (A2LA) as recognized by NVLAP through the International Laboratory Accreditation Cooperation (ILAC) Mutual Recognition Arrangement (MRA).

    - The accreditation is based on ANSI/ISO/IEC 17025.

    - The published scope of accreditation for the calibration laboratory covers the necessary measurement parameters, ranges, and uncertainties.

Evaluation, and inspection of suppliers are performed to an extent consistent with the importance, complexity, and quantity of the item(s) being purchased and include measures to periodically confirm the validity of suppliers' certificates of conformance. For annual supplier evaluations, a grace period of up to 90-days may be used for the scheduled commencement date when conditions, such as plant operational considerations or to accommodate supplier activities, make meeting the specified schedule date impractical. For evaluation activities deferred by using this grace period, the next scheduled due date shall be based on the original scheduled date. For triennial supplier audits, the audit schedule shall be based on the month in which the audit starts. An interval extension grace period of up to 25% may be used for the scheduled commencement date when conditions, such as plant operational considerations or to accommodate supplier activities, make meeting the specified schedule date impractical. When an audit interval extension greater that one month is used, the next audit will be scheduled from the original anniversary month rather than from the month of the extended audit. The total combined time interval for any three consecutive audit intervals should not exceed 3.25 times the specified audit interval. Quality verification records are reviewed by Nuclear Oversight personnel to assure their completeness and their compliance with procurement document requirements.

17.2.7.1 Receipt Inspection and Material Testing

Receipt inspection and material testing at CPNPP is performed by qualified quality control inspectors in accordance with written procedures and instructions to assure that:

1. Materials, equipment, or components are properly identified and correspond with associated documentation.

2. Inspection records or certificates of conformance attesting to the acceptance of materials, equipment, and components are completed and are available at CPNPP prior to installation or use.

3. Materials, equipment, and components are inspected and judged acceptable in accordance with predetermined inspection instructions prior to installation or use.

4. Items accepted or released are identified as to their inspection status prior to forwarding them to a controlled storage area or releasing them for installation or further work.

5. Nonconforming items are clearly identified, controlled, and segregated where practical, until proper disposition is made.

17.2.8 IDENTIFICATION AND CONTROL OF MATERIALS, PARTS, AND COMPONENTS

Requirements are established for the identification and control of safety-related materials, parts, and components, including spare or replacement items, as well as expendable and consumable items. These requirements are consistent with the provisions of Regulatory Guides 1.33, and 1.38 as discussed in Appendix 1A(B).

Materials, parts, and components are identified and controlled to prevent the use of incorrect or defective items. Identification of items is maintained either on the item in a manner that does not affect the function or quality of the item, or on records traceable to the item.

Suppliers of safety-related materials, parts, or components are required by procurement documents to establish a system of identification and control which is consistent with the above requirements.

Procedures and instructions implementing these requirements provide for the following:

1. Verification that items received onsite are properly identified and can be traced to the appropriate documentation, such as drawings, specifications, purchase orders, manufacturing and inspection documents, nonconformance reports, or mill test reports.

2. Verification of item identification consistent with the inventory control system and traceable to documentation which identifies the proper uses or applications of the item.

17.2.9 CONTROL OF SPECIAL PROCESSES

Requirements are established for the control of special processes, which are those processes where direct inspection is impossible or disadvantageous such as welding, heat treating, nondestructive testing, and cleaning, which are consistent with the provisions of Regulatory Guides 1.30, 1.33, 1.37, 1.58, and 1.94 as discussed in Appendix 1A(B).

Special processes are performed by qualified personnel using proper equipment and in accordance with written qualified procedures and instructions. These personnel, procedures and instructions are to be qualified in accordance with applicable codes, standards, and specifications. Qualification records of special process procedures and instructions, and personnel performing special processes are filed, maintained, and available for verification.

Qualification of special processes, equipment, and personnel is the responsibility of the cognizant Managers or Supervisors.

Qualified test laboratories and consultants may be used in qualification of special processes. Procedures shall be developed which delineate the requirements for special process. These procedures shall be reviewed by Nuclear Oversight or other qualified personnel.

17.2.10 INSPECTION

Requirements are established for an inspection program to verify conformance of activities affecting quality with requirements specified for those activities. These requirements are consistent with the provisions of Regulatory Guides 1.30, 1.33, 1.39, 1.58, 1.94, 1.116, and 1.123 as discussed in Appendix 1A(B).

The Director, Nuclear Oversight is responsible for administering and implementing an effective inspection program at CPNPP. Quality Control inspections are performed by personnel who are qualified and certified in accordance with ANSI N45.2.6-1978 and who are independent of the individuals performing or directly supervising the activity being inspected. Personnel performing these inspections may be from the same department but are not from the same group that performed the work. Personnel performing inspections may be selected from among any of the Nuclear Generation departments or may be contract personnel. Qualification criteria for inspection personnel are reviewed and approved by a Level III inspector and concurred with by the Director, Nuclear Oversight. Inspection personnel have authority to stop unsatisfactory work and control further processing, delivery, or installation of nonconforming material, parts or components. The inspectors' qualification and certification records/documentations are maintained by the Nuclear Generation training program. The inspectors' qualifications and certifications are maintained current by actual performance of inspections on a periodic basis. Quality independent verifications are identified by designated inspection personnel and performed by personnel who did not perform the work as assigned by line management. These verifications are overviewed by Nuclear Oversight to ensure compliance to requirements.

Inspections at CPNPP are performed in accordance with written procedures, instructions, or checklists, appropriate to the circumstances which provide for the following:

1. Identification of characteristics and activities to be inspected, including inspection hold points.

2. Acceptance and rejection criteria.

3. Method of inspection.

4. Recording the results of the inspection and identification of the quality control inspector.

5. Indirect control by monitoring of processing methods, equipment, and personnel when direct inspection is not possible.

6. Identification of any required procedures, drawings, or specifications.

Station administrative procedures controlling the Measuring and Test Equipment program contain criteria for determining the accuracy of M&TE to be used in performing inspections depending upon the accuracy requirements of the parameters being measured.

Maintenance, repair, and modification procedures and instructions containing inspection criteria shall be reviewed by a Level II or III inspector qualified in accordance with ANSI N45.2.6-1978 to ensure that adequate inspection hold points are included and that the inspection methods are adequate. Criteria contained in appropriate station administrative procedures and in applicable codes and standards shall be used in determining when inspections and tests are required.

In addition, administrative control procedures and instructions are reviewed by Nuclear Oversight to assure that required controls are included and to provide for the necessary reviews for the assignment of inspection hold points.

Inspection results are documented in accordance with procedures and instructions developed and approved for that activity. Inspection results are evaluated and then acceptability determined by individuals qualified to perform that function in accordance with the station training program. Records of the evaluations are documented and retained in the station quality records.

Contractors performing work at CPNPP and equipment and material suppliers are required to work under inspection programs consistent with applicable codes and standards. These contractors and suppliers are required to provide work plans or inspection and fabrication procedures or outlines, which are reviewed for adequacy by NP personnel.

17.2.11 TEST CONTROL

Requirements are established for the control of testing of safety-related systems, equipment, and structures. These requirements are consistent with the provisions of Regulatory Guides 1.30, 1.33, 1.58, 1.68, 1.68.2, 1.94, and 1.116 as discussed in Appendix 1A(B).

17.2.11.1 Test Program

Preoperational and initial startup testing is performed in accordance with Section 14.2 of the FSAR.

Surveillance testing is performed during the operational phase to verify continuing operational readiness and adequacy for those systems and components which are normally in a standby condition and to evaluate whether there has been any degradation of performance, or any departure from the prescribed operating conditions for the systems or components normally in service.

Tests are performed following station modifications or repairs to demonstrate satisfactory performance prior to placing affected items in service. When pressure boundaries are breached functional tests shall be conducted to the extent required to demonstrate acceptability of the repair or maintenance.

17.2.11.2 Test Procedures

Testing is identified, documented, and controlled in accordance with written administrative procedures. Each test is accomplished in accordance with written test procedures by qualified personnel.

The administrative procedures controlling the test program identify the necessary test procedures, the provisions to be included in those procedures, the method of reviewing and approving those procedures, and the methods for documenting and evaluating the results.

Test procedures include the following provisions as appropriate:

1. Prerequisites - those items of work which must be completed prior to establishing initial conditions for the test, including:

    a. Calibrated instrumentation;

    b. Adequate and appropriate equipment;

    c. Initial conditions and completeness of the item to be tested; and

    d. Suitable environmental conditions, if applicable.

2. Special precautions - items needed for safety of personnel or equipment. Special situations where caution or extraordinary attentiveness to operational circumstances is required.

3. Instructions for performing the test - steps required to conduct the test, observations to be made, data to be recorded.

4. Acceptance criteria - criteria against which the success or failure of the test can be determined.

5. Provisions for collecting, documenting, or recording test data and results.

6. Requirements and acceptance limits contained in the ISFSI or spent fuel storage cask license or Certificate of Compliance.

17.2.11.3 Test Results

Records of test results are reviewed by qualified personnel to assure acceptability. These records are retained as quality verification records in accordance with the controls described in Section 17.2.17.

17.2.12 CONTROL OF MEASURING AND TEST EQUIPMENT

Measuring and Test Equipment (M&TE) used for safety-related structures, systems and components are highly reliable, commercial grade items. The Vistra OpCo Quality Assurance Program provides measures for the control of M&TE used as the basis for acceptance in inspection, testing, and measurement activities which affect quality.

The Nuclear Generation organization is responsible for the development of procedures for the M&TE control program. These procedures delineate responsibilities for the implementation of this program and methods for the procurement, handling, storage, control, scheduling, and calibration of M&TE and reference standards. For the operations phase, these methods are consistent with the provisions of Regulatory Guide 1.33 as discussed in Appendix 1A(B).

Vistra OpCo Nuclear Oversight performs pre-award evaluations/surveys as well as periodic evaluations to assure adequacy and effective implementation of the M&TE program.

M&TE and reference standards are traceable to their calibration records. These devices are labeled or tagged to indicate the next calibration due date or otherwise controlled in accordance with approved procedures which ensure only M&TE and reference standards with current calibration are utilized.

Periodic calibration and adjustment of M&TE is performed and controlled to assure accuracy is maintained within limits necessary to verify that design and operating condition requirements have been met. M&TE is normally calibrated against reference standards which have an uncertainty of no more than one fourth (1/4) of the required uncertainty of the M&TE being calibrated. If this 4:1 accuracy requirement is not reasonably achievable, a documented evaluation of the adequacy of the calibration is performed and approved by the responsible Engineering group.

Calibrating standards have accuracy greater than or equal to reference standards being calibrated. If equal accuracy is used, the basis for calibration is documented and approved by the Vistra OpCo manager of the organization which is responsible for the calibration.

M&TE and reference standards are traceable to nationally or internationally recognized standards or natural physical constants. Where no nationally or internationally recognized standard or natural physical constant exists, the basis for calibration is documented and approved by the Vistra OpCo manager of the organization which is responsible for the calibration.

When M&TE or reference standards are lost or found to be out of calibration, a documented review is conducted to determine the validity of all inspection, test and/or measurement results gained through the use of the affected device since its last acceptable calibration. Corrective action is taken for items determined to be suspect.

Contractor and supplier organizations which provide engineering/calibration services to Vistra OpCo are responsible for implementing measures to ensure that M&TE accuracy is maintained within required limits. The M&TE programs of these organizations shall satisfy the Vistra OpCo M&TE program requirements.

17.2.13 HANDLING, STORAGE, AND SHIPPING

Requirements are established for the control, handling, storage, shipping, cleaning, and preservation of material and equipment in accordance with established instructions, procedures, or drawings. These requirements are consistent with the provisions of Regulatory Guides 1.33, 1.38, and 1.39 as discussed in Appendix 1A(B) and include the following provisions, as necessary:

1. For critical, sensitive, perishable, or high value items, specific written procedures and instructions for handling, storing, packing, shipping, and preserving are used. These procedures and instructions reflect design and specification requirements such as inert gas atmosphere, specific moisture content levels, and temperature levels, and reflect manufacturers recommendations in regards to special handling and storage requirements such as shelf life and environmental controls.

2. Personnel responsible for handling these special items are qualified to the extent required by these special handling instructions.

3. Special handling tools and equipment are inspected and tested in accordance with written procedures to verify that they are adequately maintained.

17.2.14 INSPECTION, TEST, AND OPERATION STATUS

Requirements are established for identification and control of the inspection, test, and operating status of safety-related structures, systems, and components. These requirements are consistent with the provisions of Regulatory Guide 1.33 as discussed in Appendix 1A(B).

Written procedures and instructions prescribe the use of tags, labels, and logs to indicate the inspection, test, and operating status of systems and equipment at CPNPP. These procedures and instructions also provide for tagging of nonconforming, inoperative, or malfunctioning equipment to prevent inadvertent use. In addition, these procedures and instructions identify those individuals who are authorized to apply or remove those tags and labels and provide for the use of logs to maintain the status of tags and labels in use at CPNPP.

CPNPP personnel and contractor personnel working onsite are instructed regarding the purpose of, and precautions associated with, the various tags and labels used at CPNPP. Proper use of tags and labels to indicate inspection, test, and operating status is verified through evaluations by the Nuclear Oversight.

17.2.15 NONCONFORMING MATERIALS, PARTS, OR COMPONENTS

Requirements are established for the control of nonconforming materials, parts or components. These requirements are consistent with the provisions of Regulatory Guides 1.33, 1.38, and 1.123 as discussed in Appendix 1A(B).

Material, parts, or components found nonconforming through review, inspection, or testing are controlled by administrative procedures. These procedures provide for the following:

1. Identification of nonconforming items, prior to installation, by use of nonconformance tags, and segregation of those items, if practical, to prevent inadvertent use pending proper disposition and reinspection.

2. Identification of those individuals or organizations responsible for disposition of nonconforming items.

3. Preparation of nonconformance documents which identify nonconforming items and describe the nonconformance, the disposition of the nonconformance, and the

reinspection or testing performed to determine the acceptability of the item after the disposition has been completed.

4. Review of nonconformance documents written on installed plant equipment to determine impact on operability. The administrative controls assure that nonconforming materials do not affect the operability of safety related equipment in violation of Technical Specification requirements.

5. Conditional releases allow issuance of nonconforming items from the warehouse for installation, testing, and operation, pending disposition of the nonconformance. For nonconforming items installed with a conditional release, and affecting Technical Specifications, credit may be taken for Technical Specification operability of the item, provided that: a) resolution of the nonconforming condition is tracked, and b) evaluation of the nonconforming condition supports operability of the component. Each conditional release also describes any limitations or special precautions required. Conditional releases are periodically evaluated as to their status and the results forwarded to management for their review.

6. Verification of the acceptability of rework/repair of items by reinspection or testing of the item as originally performed or by a method which is equivalent to the original inspection and testing method.

7. Nonconformance reports which are dispositioned “use as is” or “repair” are made part of the quality verification records associated with the items.

8. Periodic analysis of these reports to be performed and forwarded to management to show quality trends.

Responsibility for the implementation of activities related to nonconformance control including disposition and closeout is assigned to the cognizant manager of the area of concern. Nonconformances which are resolved by repair or use-as-is dispositions are reviewed and approved by Engineering.

Independent evaluation of activities related to nonconformance control are performed by appropriate Nuclear Oversight personnel or designee.

Marking and segregation of nonconforming items, when required, are addressed in station procedures. Compliance with these administrative requirements is verified through the station evaluation program.

17.2.16 CORRECTIVE ACTION

Requirements are established for the identification and correction of conditions adverse to quality. These requirements are consistent with the provisions of Regulatory Guide 1.33 as discussed in Appendix 1A(B). The Director, Organizational Effectiveness is responsible for administrating and facilitating the corrective action program.

Conditions adverse to quality, such as failures, malfunctions, deficiencies and deviations, identified through review of documents, evaluations, or experience during operation, are documented and dispositioned. Significant conditions adverse to quality are evaluated to

determine the cause of the condition and the corrective action to be taken to preclude recurrence.

Reports of significant conditions adverse to quality are reviewed by the Operation Review Committee and that committee's decisions and/or recommendations regarding corrective action are forwarded to appropriate management personnel. Follow-up reviews to verify proper implementation of corrective action are conducted by Nuclear Oversight personnel.

17.2.17 QUALITY ASSURANCE RECORDS

Requirements are established for the identification, collection, and storage of quality assurance records. These requirements are consistent with the provisions of Regulatory Guides 1.33 and 1.88 as discussed in Appendix 1A(B).

Sufficient records are maintained to provide documentary evidence of the quality of items and of the accomplishment of activities affecting quality. Records to be maintained include such items as drawings, specifications, procurement documents, nonconformance reports, corrective action reports, operating logs, personnel and procedure qualifications, results of inspections and test, material certifications and test results, and audit reports.

Quality assurance records are maintained in accordance with procedures and instructions which assign responsibilities for the collection, maintenance, and protection of records. These procedures and instructions provide a system of record identification to assure retrievability and prescribe retention periods for various types of records.

Senior Director, Engineering & Regulatory Affairs is responsible for development of procedures and instructions to implement the management requirements related to QA records.

Quality assurance records are stored in specially constructed storage facilities at CPNPP to prevent their destruction, deterioration, or theft. These storage facilities are designed, constructed, and maintained in accordance with the applicable requirements of the regulatory guides referenced above. Access to the records facilities is controlled so that only authorized personnel have access to the records areas. As allowed by ANSI N45.2.9-1974, maintenance of duplicate records, stored in a remote location may be used as an alternative to the utilization of these storage facilities, and the appropriate administrative controls for the maintenance of duplicate records are prescribed by procedures and instructions. The program for storage of records on microfilm, dual storage or in electronic format meets the preservation requirement for retention of Quality Assurance records. Electronic records should meet the intent of NIRMA Guidelines TG 11-2011, TG 15-2011, TG 16-2011, and TG 21-2011.

17.2.17.1 Record Retention

In addition to the applicable record retention requirements of Title 10, Code of Federal Regulations, the following records shall be retained for at least the minimum period indicated.

The following records shall be retained for at least 5 years:

1. Records and logs of unit operation covering time interval at each power level;

2. Records and logs of principal maintenance activities, inspections, repair and replacement of principal items of equipment related to nuclear safety;

3. All events reported pursuant to 10CFR50.73;

4. Records of surveillance activities, inspections and calibrations required by the Technical Specifications, Technical Requirements Manual, and Fire Protection Report, except as explicitly covered in Section 17.2.17.1.2;

5. Records of changes made to the procedures required by Technical Specification 5.4.1;

6. Deleted

7. Records of sealed source and fission detector leak tests and results; and

8. Records of annual physical inventory of all sealed source material of record.

17.2.17.2 The following records shall be retained for the duration of the unit Operating License:

1. Records and drawing changes reflecting unit design modifications made to systems and equipment described in the Final Safety Analysis Report;

2. Records of new and irradiated fuel inventory, fuel transfers, and assembly burnup histories;

3. Records of doses received by all individuals for whom monitoring was required by 10CFR Part 20;

4. Records of gaseous and liquid radioactive material released to the environs;

5. Records of transient or operational cycles for those unit components identified in FSAR Table 3.9N-1A;

6. Records of reactor tests and experiments;

7. Records of training and qualification for current members of the unit staff;

8. Records of inservice inspections performed pursuant to the Technical Specifications;

9. Records of Nuclear Oversight activities required by the Quality Assurance Manual;

10. Records of reviews performed for changes made to procedures or equipment or reviews of tests and experiments pursuant to 10CFR50.59 to 10CFR50.59 and 10CFR72.48, as applicable;

11. Records of meetings of the SORC and the ORC;

12. Records of the service lives of all hydraulic and mechanical snubbers required by the Technical Requirements Manual including the date at which the service life commences and associated installation and maintenance records;

13. Records of secondary water sampling and water quality;

14. Records of analyses required by the Radiological Environmental Monitoring Program that would permit evaluation of the accuracy of the analysis at a later date. This should include procedures effective at specified times and QA records showing that these procedures were followed; and

15. Records of reviews performed for changes made to the OFFSITE DOSE CALCULATION MANUAL and the PROCESS CONTROL PROGRAM.

16. Records of radioactive shipments.

17.2.17.3 The following additional record retention requirements apply to the Dry Cask Storage System structures, systems, and components that are classified as important to safety in accordance with 10CFR72 and NUREG/CR-6407, "Classification of Transportation Packaging and Dry Spent Fuel Storage System Components According to Importance to Safety":

1. Documentary evidence that material and equipment conform to procurement specifications shall be retained for the life of the ISFSI or spent fuel storage cask as defined in the applicable appendix to the CPNPP QA Manual.

2. Records pertaining to the design, fabrication, erection, testing, maintenance, and use of structures, systems, and components important to safety shall be retained until the NRC terminates the license or Certificate of Compliance (CoC).

3. Records showing the receipt, inventory (including location), disposal, acquisition, and transfer of special nuclear material including spent fuel must be retained for as long as the material is stored and for a period of 5 years after the material is disposed of or transferred out of the ISFSI. These records must include, as a minimum, the name of the shipper of the material to the ISFSI, the estimated quantity of radioactive material per item (including special nuclear material in spent fuel), item identification and seal number, storage location, onsite movements of each fuel assembly or storage canister, and ultimate disposal. These records must be kept in duplicate at separate locations sufficiently remote from the original records that a single event would not destroy both sets of records.

17.2.18 AUDITS

Requirements are established for an Audit program. The Audit program is consistent with the applicable portions of Regulatory Guides 1.33, 1.144, and 1.146 as discussed in Appendix 1A(B).

Planned and periodic audits are performed in accordance with written procedures to verify compliance with all aspects of the quality assurance program. Audits shall be performed at the intervals designated herein for each audit area. Schedules shall be based on the month in which

the audit starts. Audit reports shall be forwarded to the Senior Vice President & Chief Nuclear Officer and to the management positions responsible for the areas audited within 30 days after completion of the audit by the auditing organization. Responsibility for the evaluation program has been assigned to the Director, Nuclear Oversight. Audits are conducted or coordinated by Nuclear Oversight personnel and shall include evaluation and examination of the following quality-related activities:

1. The conformance of unit operation to provisions contained within the Technical Specifications and applicable license conditions at least once per 24 months;

2. The performance, training and qualifications of the entire unit staff at least once per 24 months;

3. The results of actions taken to correct deficiencies occurring in unit equipment, structures, systems or method of operation that affect nuclear safety, at least once per 24 months;

4. The performance of activities required by the Operational Quality Assurance Program to meet the criteria of Appendix B, 10CFR50, at least once per 24 months;

5. The fire protection programmatic controls, including the implementing procedures, program implementation, and fire protection equipment at least once per 24 months by qualified licensee Nuclear Oversight personnel and qualified offsite fire protection engineers;

6. The fire protection equipment and program implementation at least once per 36 months utilizing an outside independent fire protection consultant.

7. The Radiological Environmental Monitoring Program and the results thereof at least once per 24 months;

8. The OFFSITE DOSE CALCULATION MANUAL and implementing procedures at least once per 24 months;

9. The PROCESS CONTROL PROGRAM and implementing procedures for processing and packaging of radioactive wastes at least once per 24 months;

10. The performance of activities required by the Quality Assurance Program for effluent and environmental monitoring at least once per 24 months.

11. Any other area of unit operation considered appropriate by the ORC or the Senior Vice President & Chief Nuclear Officer; and

12. The performance of activities required by the Technical Requirements Manual at least once per 24 months.

13. The performance of activities required by the Operational Quality Assurance Program to meet the criteria of subpart G, 10CFR72, at least once per 24 months.

17.2.18.1 Audit Organizations

Organizations performing activities affecting quality that are subject to evaluation include the following:

1. The nuclear engineering, operations, regulatory affairs and Nuclear Oversight organizations for CPNPP.

2. Contractors, consultants, and suppliers of quality related items or service. NVLAP and A2LA accredited commercial grade calibration suppliers do not require audit when evaluated in accordance with Section 17.2.7.

17.2.18.2 Nuclear Oversight

As part of the Quality Assurance Program Nuclear Oversight:

1. Utilizes an audit planning document which defines the organizations and activities to be evaluated and the frequency of the audits. The audit schedule is performance-based and additional audits may be scheduled based upon program or functional area performance or other factors that indicate the need for increased assessment. For audits, other than those audit areas with a maximum frequency specified by regulation (Security and Emergency Plan), an interval extension grace period of up to 25% may be used for the scheduled commencement date when conditions, such as plant operational considerations or to accommodate performance-based observations of activities related to the audit area, make meeting the specified schedule date impractical. When an audit interval extension greater than one month is used, the next audit for that particular audit area will be scheduled from the original anniversary month rather than from the month of the extended audit.

2. Requires auditors to be familiar with the type of activities to be evaluated and have no direct responsibilities in the area being evaluated.

3. Provide audit checklists or other objective guidelines to identify those activities which affect quality.

4. Requires examination of the essential characteristics of the quality activity examined.

5. Requires an audit report be prepared that notes the extent of examination and deficiencies found.

6. Requires the audit report be sent to management responsible for the area evaluated for review and corrective action for deficiencies.

7. Requires corrective action taken as result of the audit be reported.

8. Requires re-audit of deficient areas when it is considered necessary to verify implementation of required corrective actions.

9. Requires vendors/subcontractors to comply with items 1-8 above to the extent necessary.

Documentation of audits performed by participating contractors is made available to Nuclear Generation for evaluation.

17.2.18.2.1 Nuclear Generation Verification

In summary, Nuclear Generation verifies conformance of the regulatory audit requirements by three methods:

1. Review of contractor's/vendors' quality assurance methods for auditing.

2. Review of documentation of the audit report performed by these contractors/vendors.

3. Internal and external evaluations performed by Nuclear Oversight personnel.

17A LIST OF QUALITY ASSURED ITEMS

17A.1 SCOPE OF QA APPLICABILITY

This appendix identifies major safety-related items for Comanche Peak Nuclear Power Plant (CPNPP) within the scope of the nuclear quality assurance (QA) programs established to meet the requirements of Appendix B to 10 CFR Part 50. Safety-related items listed require special consideration during design, purchasing, fabrication, handling, shipment, storage, cleaning, erection, installation, inspection, testing, operation, maintenance, repair, refueling, and modification. These items include structures, systems, and components or portions thereof that prevent or mitigate the consequences of postulated accidents that could cause undue risk to the health and safety of the public.

This appendix also identifies major non-safety related items for CPNPP and the appropriate level of quality assurance where applicable.

Table 17A-1 (the Q-List) identifies the systems and components and their applicable quality assurance requirements for the operation of CPNPP.

The quality assurance applied to the safety related structures, systems, and components as identified in Table 17A-1 are consistent with the safety function that a structure, system, or component is to perform and are determined by engineering as a design function. Table 17A-2 provides the quality assurance notes applicable to Table 17A-1 and the classification of equipment to which they are applied.

Respective descriptions of the quality assurance related activities of these organizations (Criteria I through XVIII of the Appendix B to 10 CFR Part 50) are presented in Sections 17.1 and 17.2. As a minimum, Table 17A-1 includes all safety-related structures, systems, and components discussed in Section 3.2.1.1 (Seismic Category I) and Section 3.2.1.2 (Seismic Category II).

Table 17A-1 also includes other items of the plant not classified as safety-related but for which some degree of quality assurance applies. These items augment reliable performance of safety-related items. In order to ensure that appropriate quality assurance measures are applied to these items and other programmatic activities during the operations phase, Vistra OpCo has established a specifically structured non-Appendix B quality assurance program to augment the Appendix B quality assurance program for safety-related systems and activities described in Section 17.2. This specifically structured program is defined in an Appendix to the CPNPP QA Manual.

The existing quality program controls established to meet 10CFR50 Appendix B may be applied to the Dry Cask Storage System structures, systems and components that are important to safety. The applicability of existing quality assurance program requirements for the Dry Cask Storage System are defined in an Appendix to the CPNPP QA Manual.

Changes to FSAR Table 17A-1 are reviewed and accepted by the Director, Nuclear Oversight. The FSAR amendment promulgating the change is approved and submitted by the Senior Vice President & Chief Nuclear Officer.

17A.2 CRITERIA FOR APPLICATION OF QA

Because the Table 17A-1 serves as a basis for identifying safety- related structures, systems, and components which require consideration in accordance with the QA programs, the following criteria were applied for establishment of the list:

1. Safety Classification

   Systems and components, consistent with their function, were designated as Safety Class 1, 2, 3, 1E, Non-1E, N/A or non-nuclear safety (NNS) (see Section 3.2.2). Safety-related components or their portions designed to the ASME B&PV Code, Section III, are subject to QA programs, and are listed in Table 17A-1.

2. Seismic Category Classification

   a. Seismic Category I

      Structures, systems, and components designated as seismic Category I in accordance with Reg.Guide 1.29 are subject to QA and are listed in the Table 17A-1.

   b. Seismic Category II

      Systems and components which require some seismic design requirements in accordance with Reg.Guide 1.29, but not to the extent of seismic Category I, are listed as seismic Category II.

   c. Seismic Category NONE

      Those systems and components which have no seismic design requirements are listed as seismic Category “NONE”.

3. Additional Classification of Mechanical Components

   All NNS piping and plumbing designated as Class 5 are listed. See Section 3.2.2 for a discussion of the Class 5 categorization.

4. Fire Protection

   Systems and components provided for fire protection for safety- related areas and subject to quality assurance requirements as described in Section 9.5.1 are listed.

5. Radioactive Waste Management Systems (RWMS)

   Systems and components which process radioactive waste are included. The boundaries of RWMS are shown on the flow diagrams.

6. Other

Those systems and components which are given some QA because of criteria not discussed above are also listed. Some components which have no QA requirements are also listed to satisfy information requirements of FSAR Section 3.2 and to provide clarification on QA applicability.

17A.3 INDEX

Table 17A-1 is divided into the following systems:

SYSTEM NO.	SYSTEM
1.	Reactor Coolant System (RCS)
2.	Chemical and Volume Control System (CVCS)
3.	Boron Thermal Regeneration Subsystem (BTRS)
4.	Safety Injection System (SIS)
5.	Residual Heat Removal (RHR) System
6.	Boron Recycle System (BRS)
7.	Containment Spray System (CSS)
8.	Containment Isolation System
9.	Combustible Gas Control System
10.	Component Cooling Water System (CCWS)
11.	Station Service Water System (SSWS)
12.	Main Steam, Reheat and Steam Dump System
13.	Auxiliary Feedwater System
14.	Steam Generator Feedwater System
15.	Diesel Generator, Fuel Oil, and Auxiliary Systems
16.	Spent Fuel Pool Cooling and Cleanup System
17	Liquid Waste Processing System (LWPS)
18.	Gaseous Waste Processing System (GWPS)
19.	Solid Waste Management System (SWMS)
20.	Demineralized and Reactor Makeup Water System
21.	Vents and Drains System

SYSTEM NO.	SYSTEM
22.	Containment Ventilation Systems
23.	Control Room Air-Conditioning System
24.	Safeguards Building HVAC System
25.	Fuel Building Ventilation System
26.	Diesel Generator Building Ventilation System
27.	Uncontrolled Access Area Ventilation System
28.	Primary Plant Ventilation System
29.	Auxiliary Building HVAC System
30.	Service Water Intake Structure Ventilation System
31.	Chilled Water Systems
32.	Process Sampling System
32.a	Post Accident Sampling System
32.b	Secondary Sampling System
33.	Fuel Handling Equipment and Fuel Assemblies
34.	Containment Building Miscellaneous Equipment
35.	Miscellaneous Handling Equipment
36.	Structures
37.	Electrical Equipment
38.	Radiation Monitoring System
39.	Fire Protection System
40.	Plant Gas System
41.	Instrumentation and Control Equipment
42.	Tornado Venting Components
43.	Compressed Air Systems
44.	Protective Coatings
45.	Potable and Sanitary Water System

SYSTEM NO.	SYSTEM
46.	Condensate System
47.	Auxiliary Steam System
48.	Steam Generator Blowdown & Cleanup System
49.	Pipe Whip Restraints
50.	Meteorological Instrumentation
51.	Uninterruptible Power Supply (UPS) Area Air-Conditioning System
52.	Turbine Plant Cooling Water System
53.	Condensate Polishing System
54.	Condenser Vacuum and Waterbox Primary System
55.	Heater Drains System
56.	Chemical Feed System
57.	Security Systems
58.	Chlorination Systems

Notes

1. Services provided to support a safety or other necessary function:
   a. Emergency power - automatic loading
   b. Emergency power - manual loading
   c. Component cooling water
   d. Service water
   c. Steam
2. Portions of equipment containing component cooling or service water are Safety Class 3, Code Class 3.
3. Deleted.

3a Deleted.

4. Deleted.
5. Deleted.

TABLE 17A-1
LIST OF QUALITY ASSURED STRUCTURES, SYSTEMS AND COMPONENTS

6. Deleted.
7. Safety classes for fluid system components are defined by the engineering flow diagrams and are in accordance with ANSI N18.2, Nuclear Safety Criteria for the Design of Stationary Pressurized Water Reactor Plants except as descr bed in Section 3.2.2. Safety classes for electrical, instrumentation and control components are defined by the one-line diagrams, electrical wiring diagrams, and instrumentation and control diagrams. Safety classes for reactor containment pressure boundary components are in accordance with ANSI N18.2.
8. The Main Steam Isolation and Bypass Valves were originally procured to ASME Class 1 as permitted by paragraph NA-2134 of the ASME Code, Section III. Procurement of ASME Code components to classifications higher than their end use is common (and acceptable); however; the application shown is the required classification for system and for ASME XI activities.
9. Parts must meet the structural integrity requirements of the specification and applicable quality assurance requirements of 10 CFR Part 50, Appendix B.
10. Failure can cause no nuclear safety problem, although an economic loss may result.
11. This component is Safety Class 3 under the definition 2.2.3(1), (3), or (4) of ANSI N18.2-1973 and qualifies for no special seismic design by meeting the four following conditions. Portions of systems in which this component is located that perform the same safety function likewise qualify for no special seismic design.

    Conditions to be met for exemption are the following:

    a. Failure would not directly cause a Condition III or IV event (as defined in ANSI N18.2-1973, Nuclear Safety Criteria for the Design of Stationary Pressurized Water Reactor Plants).

    b. There is not safety function to mitigate nor could failure prevent mitigation of the consequences of a Condition III or IV event.

    c. Failure during or following any Condition II event would result in consequences no more severe than allowed for a Condition III event.

    d. Routine post seismic procedures would disclose loss of the safety function.
12. The applicable code or standard provided is the primary ASME code or industry standard which applies to the given component. Additional information about the design requirements is provided in the referenced FSAR Sections. IEEE 323 applies to harsh equipment only. ASME: American Society of Mechanical Engineers. III stands for Section III of the ASME Boiler and Pressure Vessel (B&PV) Code. VIII stands for Section VIII of the ASME B&PV Code. Pressure vessels which are part of the RCPB meet the requirements of 1971 Version, with application of all Addenda through and including the Summer 1972 Addenda. Pumps, valves, and piping which are part of the RCPB meet the requirements of the 1971 Version, with application of all Addenda through and including the Winter 1972 Addenda. Later Code versions may be used optionally.
13. Not Used
14. Must maintain fuel array to prevent criticality under adverse conditions including occurrences of the SSE.
15. To be safety classified, failure of the tool must be directly a nuclear safety problem. If a nuclear safety problem arises from tool failures combined with a procedural failure thereafter, the tool is Non-Nuclear Safety.
16. Failure inside isolable reactor Containment prevents substantial release to the environment of radioactive gases from damaged spent fuel.
17. Deleted.

TABLE 17A-1
LIST OF QUALITY ASSURED STRUCTURES, SYSTEMS AND COMPONENTS

18. Any reactor vessel internal, the single failure of which could cause release of a mechanical piece having potential for direct damage (as to the vessel cladding) or flow blockage, shall be classified to a minimum of Safety Class 2.
19. These items are not required as mechanical supports for CRDM housings, but are required to ensure functioning of the control rods.
20. Failure could cause a LOCA, but less than a Condition III loss-of-coolant.
21. This equipment is not commercially available as ASME Code, Section III, Class 3.
22. This equipment is included in the scope of IEEE 387; in that, ANSI N18.2 endorses IEEE-308 which in turn endorses IEEE-387, for diesel generators. IEEE-387 provides principal design criteria, etc., for individual diesel generator units which enable them to meet their functional requirements as part of the standby power supply.
23. Critical parts required to maintain structural integrity during a seismic event are subjected to QA program.
24. These devices will remain in place following a SSE.
25. Component supports are designed in accordance with ASME B&PV Code, Section III, Class 3 but fabricated to AISC -1970.
26. Deleted.
27. Deleted.
28. Deleted.
29. Deleted.
30. Applies only to that bolting involved with coastdown function.
31. Tubing, valves and fittings connected to ASME Class 2 and 3 systems are procured to ASME Section III Class 2 and 3 requirements. Instruments and racks are not covered by ASME Code. Also see Note 41.
32. Deleted.
33. The requirements of FSAR Section 6.1B.2 for Containment and Section 12.3.1.2 for radiation areas outside Containment are implemented by approved procedures. These procedures will establish the requirements necessary to ensure a good quality coating system. The fire protection requirements for protective coatings are in FSAR Section 9.5.1.5.3. The quality assurance requirements for the protective coatings program for Service Level I are in accordance with EPRI Report 1003102, “Guideline on Nuclear Safety-Related Coatings”, Revision 1 (formerly TR-109937) and ASTM D 5144-00, Standard Guide for Use of Protective Coating Standards in Nuclear Power Plants.
34. The quality requirements of Branch Technical Position ETSB 11-1, Rev. 1, are satisfied. Specifically, codes and standards required in the design, fabrication, inspection and testing of pressure vessels, tanks, heat exchangers, piping and valves, and pumps for the liquid and solid radwaste systems, and the steam generator blowdown processing system comply as a minimum with Table 1 of Branch Technical Position ESTB 11-1, Revision 1, except for the instance stated in Note 83 to this Table. Note: This is not within the scope of FSAR Section 17.2. Where “Note 34” is used for safety-related equipment (Safety Class 1, 2, or 3, or Seismic Category I), the QA provisions of Appendix B envelope and satisfy the requirements of ETSB 11-1. The scope of ESTB 11-1 is defined in the engineering flow diagrams by "RWMS" boundary demarcation.
35. ATCOR topical report no. 132A gives a breakdown of system components and applicable design codes.

TABLE 17A-1
LIST OF QUALITY ASSURED STRUCTURES, SYSTEMS AND COMPONENTS

36. The applicable code for the Containment is the proposed Standard Code for Concrete Reactor Vessels and Containment (April 1973) issued for trial use and comments. It was developed by the Joint ACI-ASME Technical Committee on Concrete Pressure Components for Nuclear Service (see Section 3.8.1.2.1).

37. Deleted.

38a. This applies to safety-related and non-safety related instruments which are connected to nuclear safety related piping or ducting with seismic Category I tubing and supports.

38b. This applies to non-safety related instruments connected to NNS piping or ducting by NNS tubing and supports.

39. All pressure switches are differential pressure switches with the low side open to atmosphere.

40. Code Class 1, 2 or 3 indicates item within ASME Code Boundary. Code Class "-" indicates item not within ASME Code Boundary.

41. The ASME III Code (excluding NA-4000, NA-5000, and NA-8000) shall apply to all tubing, valves and fittings. Tubing, valves and fittings are procured as ASME material but will not be installed with Third Party Inspection, Code Stamping, and Code Data Reports as specified in ASME Subsection NA-5000 and NA-8000. Site fabrication and installation of tubing, valves and fittings will be in accordance with an NRC approved QA program governing non-ASME work which meets the requirements of Appendix-B to 10 CFR part 50 (excluding ASME III Subsection NA-4000). Piping installed between root valves and instruments is subject to the same requirements as stated previously in this note for instrument tubing, valves and fittings. Tubing and valve supports shall be installed as Seismic Category I but shall not comply with ASME III Subsection NF requirements. See Section 3.9B.3.4.3 for details.

42. The quality assurance requirements of Appendix A of the Branch Technical Position APCSB 9.5-1 of Standard Review Plan, Section 9.5.1, Revision 1, are satisfied.

43. The quality assurance requirements of Branch Technical Position MEB 3-1 and APCSB 3-1 are satisfied.

44. Process piping meets quality assurance requirements as set forth in mechanical specification 2323-MS-46B, "Non-Nuclear Pipe Hanger and Supports" and mechanical specification 2323-MS-100, "Piping Erection". Tubing and tubing supports used in NNS process piping, control piping, and sampling piping meets the qualify assurance requirements as set forth in specification CPES-I-1018, Installation of Piping/Tubing and Instrumentation Class 5 piping and its supports are designated Seismic Category II or None. Seismic Category II is utilized for piping included in ASME Section III stress analyses, high energy lines, and other special cases indicated by engineering evaluation. Seismic Category None is normally utilized for 2 inch and under piping, and 4 inch and under air filled copper tubing/pipe, unless otherwise indicated by engineering evaluation. Seismic Category II piping has Seismic Category II supports. Seismic Category NONE piping has Seismic Category NONE supports. In Category I Buildings, all Class 5 piping has been evaluated to show that seismic failure is not cred ble and therefore, the safety function of nuclear safety-related items is not adversely affected.

45. See system No. 40 for instrument piping (tubing). Piping includes pipe, tubing, fittings and valves.

46. Safety function is achieved by remaining in place. Component safety function is non-active.

47. Applicable codes and standards for concrete radiation shielding are listed in Section 3.8.4.2.

48. Only portions that furnish support to CRDMs, are Safety Class 1.

49. Deleted.

50. Deleted.

51. Supports for NNS instrumentation lines, instrument air lines, and pneumatic signal lines installed in Seismic Category I areas shall be Seismic Category II or NONE. Seismic Category NONE supports shall only be used if engineering evaluation shows that a seismic failure would not adversely affect the safety function of nuclear safety related items.

TABLE 17A-1
LIST OF QUALITY ASSURED STRUCTURES, SYSTEMS AND COMPONENTS

52. Masonry walls have been evaluated for seismic interactions (remained non-seismic), removed, or replaced with seismically designed walls of other material.
53. This load handling equipment satisfies NUREG-0554 single-failure-proof requirements. Seismic Category I denotes the capability to retain control of the lifted load and to maintain structural integrity during and after a seismic event. The loading combinations include OBE and SSE with lifted load except for the polar crane due to the low probability of SSE with lifted load (less than 1×10^{-7} per year). The polar crane criteria is discussed in FSAR Section 9.1.4.3.2.
54. Fire dampers are functionally part of fire barriers but are physically located in ventilation ducts and penetrations. The safety class designation on ventilation diagrams does not apply to the fire dampers. Fire dampers which are required to remain open after an SSE have thermal links that are designated seismic Category II and are qualified to keep the damper open.
55. The tank boundary extends to the first weld connecting the penetration nozzles to system piping outside the tank. The tank and associated piping inside the tank is not N-stamped.
56. The application of R.G. 1.97 is applied to those channels identified in FSAR Section 7.5.
57. The Class 5 piping and valves in these 2" and under seismic Category II lines are seismically analyzed and are supported by seismic Category II supports. Installation requirements are the same as other Class 5, seismic Category II pipes.
58. Excluding existing buried yard piping. QA requirements of Appendix A to BTP APCSB 9.5-1 of Standard Review Plan Section 9.5.1 Revision 1 are to be satisfied for future activities associated with buried yard piping that supplies fire protection water to safety related buildings.
59. QA for water extinguishers limited to UL listing.
60. Deleted.
61. Deleted.
62. This component has been qualified as seismic category I by analysis.
63. Applicable where wall is supported by structural steel specified seismically, e.g., all access blockouts that have removable block closures have seismically designed steel supports to prevent collapse of the blocks.
64. Application of modified GDC-4 (leak-before-break) removes the need for non-crushable insulation. The non-crushable insulation may be replaced.
65. The leak testing of the instrument tubing between the instrument isolation valve and the instrument will be accomplished during normal instrument calibration. Tubing systems previously pressure tested as being satisfactory, which were later repaired or replaced, shall not require an additional pressure test prior to initial plant startup but shall be evaluated under an in-service leak test program.
66. For the Non-1E portion of the AMSAC, the requirements of Generic Letter 85-06 will be implemented through application of a quality assurance program that satisfies applicable requirements of Regulatory Guide 1.33, Revision 2.
67. Seismic Category II conduit supports are subject to Operations Quality Assurance Note B.
68. ASME III is the primary code for design and/or fabrication. This item is not within the ASME III, jurisdictional boundary.
69. This applies to auxiliary relay racks 1 and 2 only. The only 1E function of the Auxiliary Relay Racks is to provide isolation.
70. Seismic Category II anchor bolts, structural steel and/or mounting are subject to Operations Quality Assurance Note B.

TABLE 17A-1
LIST OF QUALITY ASSURED STRUCTURES, SYSTEMS AND COMPONENTS

71. NNS HVAC dampers are Seismic Category NONE. Operations Quality Assurance Note B applies to mounting and supports in Seismic Category II ductwork.
72. Seismic Category II mounting, anchors, and/or supports are subject to Operations Quality Assurance Note B.
73. Critical parts of these radiation monitors subject to Operations Quality Assurance Note B are the lead shielding for the detectors and the supports and anchors for those shields.
74. Critical parts of these radiation monitors subject to Operations Quality Assurance Note B are the lead shielding and fluid system pressure boundary and the supports and anchors for these items.
75. Valve required during and after a tornado.
76. Only Control Room Blowout Panels are Seismic Category II (to remain closed) and subject to Operations Quality Assurance Note B.
77. Certain non-safety related (Seismic Category NONE) instrumentation and controls located outside Seismic Category I areas are denoted as Class 1E. These devices are fully Class 1E except for seismic qualification. Seismic qualification and installation are provided to the extent practical considering that the specific location (e.g. building) is not seismically qualified. See Figure 7.1-3 (Sht. 16), Section 7.2.1.1.6, Section 8.3.1.4.1, and Section 10.4.7 for descriptions of these items.
78. Includes the design features and administrative measures to assure the safe handling of heavy loads.

TABLE 17A-1
LIST OF QUALITY ASSURED STRUCTURES, SYSTEMS AND COMPONENTS

79. Valve operators for safety related valves are classified and have QA applicability as follows:

Valve Operator Type	Applicable Safety Class	Code/ Standard	Code Class	Seismic Category	Quality Assurance	Remarks
Self Actuated (e.g. check valve, relief valve, etc.): Included in table listing because "operator" is integral to valve						
Manual: Included in the table listing because the classification of a manual “Operator” is included in the valve classification. Table 3.9B-10 identifies where handwheels are credited for manual operation of active valves.						
Extension Stems (Active)	N/A	Mfrs Stds	-	I	Note A	
Extension Stems (Passive)	N/A	Mfrs Stds	-	NONE	Note C	Note 72
Solenoid: Included in table listing because "operator” is integral to valve; however, Safety Class may be 1E or N1E with applicable corresponding standards in addition to the ANSI safety class.						
Motor (Active Vlv)	1E	IEEE 323	-	I	Note A	
Motor (Passive Vlv)	N1E	Mfrs Stds	-	NONE	Note C	
Air/hydraulic (Active Vlv*)	3, N/A**	Mfrs Std	-	I	Note A	
Air/hydraulic (Passive Vlv)	N/A	Mfrs Stds	-	I#	Note A	
Air/hydraulic (Passive Vlv)	N/A	Mfrs Stds	-	NONE##	Note C	

* Active valves for each system are identified in Tables 3.9N-10 and 3.9B-10.

** Safety Class 3 is applicable to the air/hydraulic valve operator when an air accumulator is required for the valve to perform a safety function. Otherwise, Safety Class is "N/A".

\# Operator with Class 1E Appurtenances.

Operator with non-1E Appurtenances.

80. Cables and heat shrinkable cable insulation sleeves are not seismically qualified. However, the basic standards to which cables and heat shrinkable cable insulation sleeves are procured and their associated installation requirements assure their functioning following a seismic event.

81. High energy line piping segments which are listed in FSAR Section 3.7B.2.8 as located in the Turbine Building are designated class 5 piping and classified as Seismic Category II even though the locations are in a non-seismic building. Additional analyses are performed to demonstrate that unacceptable interactions of these piping segments with Non-Category I structures and components will not occur during a seismic event. These piping segments are seismically analyzed for break postulation and seismic qualification.

TABLE 17A-1
LIST OF QUALITY ASSURED STRUCTURES, SYSTEMS AND COMPONENTS

82. Piping and supports for the Diesel Generator exhaust piping the building, from the flex ble connectors to just upstream of the exhaust relief valve, are designed, analyzed, installed and inspected to the requirements of ASME Section III, including Code Case N-253-2. In some of the pipe support qualifications, part of the material stress allowables are extracted from ANSI B31.1. In all cases, the requirements of Code Case N-253-2 were met or exceeded. The piping and associated supports are exempt from Code Stamping.
83. Radiation monitors are not designed to ASME VIII, Division 1; however, manufacturer's design standards include hydrotesting to 1.5 times design pressure and compliance with ASME IX welding requirements.
84. Steam Generator nozzle dams are used during shutdown and refueling. ANSI N18.2 is not applicable. Seismic and QA requirements apply to critical components of the nozzle dam and support frame and to the diaphragm seal.
85. Non-1E level switches installed in ASME piping are safety related for pressure boundary integrity only. There are two types:
    a. Displacement Type (ASME).
    b. Thermal Dispersion Type (Non-ASME).
86. The Safety Class 2 (containment isolation) portion of the Unit 1 personnel airlock hydraulic system contains both ASME and non-ASME components as denoted on Figure 3.8-22. The ASME code is not applicable to the tubing and hydraulic system components.
87. See Table 17A-2 for the Operations Quality Assurance Notes.
88. The Containment Air Radiation Monitor is classified as N1E because it is not required to function during or following a LOCA and is not environmentally qualified for that event. It is electrically isolated from the 1E bus during and after a LOCA; therefore, IEEE-323 does not apply. The monitor's Nuclear Safety Function is performed in normal operation and after seismic events in accordance with RG 1.45 [FSAR Section 5.2.5]. The monitor is classified as seismic Category I and is seismically qualified in accordance with IEEE-244.
89. Requirements of applicable codes meet or exceed those of CMAA 70 in applicable areas.
90. Underwater lights containing mercury (such as high pressure sodium lights) are subject to inspections and precautions and limitations that assure nuclear safety is not compromised.
91. Abandoned in place.
92. ANSI Safety Class 3 tubing, valves and fittings connected to HVAC systems may be procured to ASME Section III Class 3 requirements; however, the ASME Code is not applicable to the design or installation. ANSI Safety Class 3 tubing, valves, and fittings are designed and installed to seismic Category I requirements.
93. The Radial Arm Hoist Assembly (RAHA) is used during Modes 5 and 6 to aid in reactor vessel head stud removal and other refueling activities. Because the Mode 5 and 6 configuration does not meet RG 1.29, Seismic Category II requirements, the hoists and their trolleys are removed during Modes 1 through 4 and the radial arms are secured in a Seismic Category II configuration that meet the requirements of Reg. Guide 1.29, Rev. 2, Position C.2 and QA Note B.
94. Alternate penetration insert is for use in Modes 5 and 6.
95. The airlock instrumentation is a special case as descr bed in FSAR Section 6.2.4.1.3.
96. The SFP level instrument mounting brackets and anchorages were designed in accordance with the CPNPP requirements as a Seismic Category I component support. Other evaluations provided in letters TXX-15084 and TXX-15122 demonstrate that adequate and reasonable designs have been provided to support the other SFP level instrument channel components for the site's SSE.

TABLE 17A-1
LIST OF QUALITY ASSURED STRUCTURES, SYSTEMS AND COMPONENTS

97. The Westinghouse SHIELD Shutdown Seal is a separate component from the Reactor Coolant Pump No. 1 seal and located within the No. 1 seal insert package. The SHIELD Shutdown Seal is secured in a Seismic Category II configuration that meets the requirements of R.G. 1.29, Rev. 2 Position C.2, Augmented Quality Assurance and FSAR Table 17A-2 Note B.

98. Containment Recirculation Cooling Units at Containment Elevation 905 in Unit 2 only are provided with removable silencers which may be installed in Modes 5 and 6 and with the reactor de-fueled to reduce noise during refueling outages.

99. Fuel Assemblies are not classified by ANSI N18.2. Safety Class 3 id based on ANSI/ANS 51.1 (1983).

100. The portion of seismic instrumentation in the control room is installed seismic category II (i.e., seismic monitoring system cabinet).

TABLE 17A-2
QUALITY ASSURANCE SUMMARY

SAFETY CLASS	SEISMIC CATEGORY	SAFETY RELATED	OPERATIONS QA APPLIED
1	I	YES	YES, A
2	I	YES	YES, A
3	I	YES	YES, A
3, 1E	NONE	NO	YES, A
1E	I, N/A	YES	YES, A
N/A, N1E	I	YES	YES, A
NNS, N/A	II	NO	YES, B
NNS, N/A, N1E	NONE	NO	YES, C or D
NNS, N/A, N1E	NONE	NO	NO, E

Operations Quality Assurance Notes:

A. An Operations QA Program will be implemented which satisfies applicable requirements of Regulatory Guide 1.33, Rev. 2, “Quality Assurance Program Requirements” (Operations).

B. Critical parts required to maintain structural integrity during a seismic event are subjected to an Operations QA Program which satisfies applicable requirements of Regulatory Guide 1.33, Rev. 2.

C. Full QA requirements were not imposed for manufacture and/or installation; however, a specifically structured non-Appendix B QA program will be instituted during operation of equipment.

D. An Operations QA Program will be implemented which satisfies applicable requirements of Appendix A of the Branch Technical Position APCSB 9.5-1 of Standard Review Plan, Section 9.5.1, Rev. 1.

E. No formal quality assurance program is required. Normal applications of administrative controls for non-safety related items is applied.

F. Appropriate quality assurance measures are in accordance with Appendix A-1 of NEI 12-02, Revision 1, “Industry Guidance for Compliance with NRC Order EA-12-051, “To Modify Licenses with Regard to Reliable Spent Fuel Pool Instrumentation.”

I OPERATIONAL SAFETY

I.A OPERATING PERSONNEL

I.A.1 OPERATING PERSONNEL AND STAFFING

OBJECTIVE:

"Complex transients in nuclear power plants place high demands on the operators in the control room. The objective of the actions described in this task is to increase the capability of the shift crews in the control room to operate the facility in a safe and competent manner by assuring that a proper number of individuals with the proper qualifications and fitness are on shift at all times."

-NUREG 0660, pg. I.A.1-1

I.A.1.1 Shift Technical Advisor

Action Plan Requirements:

"Provide on shift at each nuclear power plant a qualified person (the shift technical advisor) with a bachelor's degree or equivalent in a science or engineering discipline with specific training in the plant response to off-normal events and in accident analysis of the plant."

"Shift technical advisors shall serve in an advisory capacity to shift supervisors. The licensee shall assign normal duties to the shift technical advisor that pertain to the engineering aspects of assuring safe operations of the plant, including the review and evaluation of operating experience."

-NUREG 0578, pg. 13

Also see NUREG 0737

CPNPP Response

Refer to revised Section 13.2.1.1, Item 5 .

I.A.1.2 Shift Supervisor Administrative Duties

Action Plan Requirements:

"The administrative duties of the shift supervisor shall be reviewed by the senior officer of each utility responsible for plant operations. Administrative functions that detract from or are subordinate to the management responsibility for assuring the safe operation of the plant shall be delegated to other operations personnel not on duty in the control room."

- NUREG 0578, pg. A-48

CPNPP Response

A list of administrative duties of the Shift Supervisor will be provided to the Vice President, Nuclear, for his review prior to fuel load.

I.A.1.3 Shift Manning

Action Plan Requirements:

"The minimum shift crew for a unit shall include three operators, plus an additional three operators when the unit is operating. Shift staffing may be adjusted at multi-unit stations to allow credit for operators holding licenses on more than one unit."

"In each control room, including common control rooms for multiple units, there shall be at all times a licensed reactor operator for each reactor loaded with fuel and a senior reactor operator licensed for each reactor that is operating. There shall also be onsite at all times, an additional relief operator licensed for each reactor, a licensed senior reactor operator who is designated as shift supervisor, and any other licensed senior reactor operators required so that their total number is at least one more than the number of control rooms from which a reactor is being operated."

"Administrative procedures shall be established to limit maximum work hours of all personnel performing a safety-related function to no more than 12 hours of continuous duty with at least 12 hours between work periods, no more than 72 hours in any 7 day period, and no more than 14 consecutive days of work without at least 2 consecutive days off."

-NUREG 0694, pg. 11

CPNPP Response

Procedures have been established to address shift manning and an overtime policy. These procedures will be implemented prior to fuel load.

CPNPP currently follows shift manning and overtime policy prescribed by 10 CFR Part 26 Subpart I which supercedes NUREG-0694 criteria.

I.A.2 TRAINING AND QUALIFICATION OF OPERATING PERSONNEL

OBJECTIVE:

"Improve the capability of operators and supervisors to understand and control complex reactor transients and accidents, and improve the general capability of an operations organization to respond rapidly and effectively to upset conditions. Increase the education, experience, and training requirements for operators, senior operators, supervisors, and other personnel in the operations organization to substantially improve their capability to perform their duties."

-NUREG 0660, pg. I.A.2-1

I.A.2.1 Immediate Upgrading of Operator and Senior Operator Training and Qualifications

Action Plan Requirements:

"A. Eligibility Requirements to be Administered an Examination.

"1. Experience*

a. Applicants for senior operator licenses shall have 4 years of responsible power plant experience. Responsible power plant experience should be that obtained as a control room operator (fossil or nuclear) or as a power plant staff engineer involved in the day-to-day activities of the facility, commencing with the final year of construction. A maximum of 2 years power plant experience may be fulfilled by academic or related technical training, on a one-for-one time basis. Two years shall be nuclear power plant experience. At least 6 months of the nuclear power plant experience shall be at the plant for which he seeks a license.

b. Applicants for senior operator licenses shall have held an operator's license for 1 year."

"2. Training

a. Senior operator*: Applicants shall have 3 months of shift training as an extra man on shift.

b. Control room operator*: Applicants shall have 3 months training on shift as an extra person in the control room.

---

*Precritical applicants will be required to meet unique qualifications designed to accommodate the fact that their facility has not yet been in operation.

---

c. Training programs shall be modified, as necessary, to provide:

1) Training in heat transfer, fluid flow and thermodynamics.

2) Training in the use of installed plant systems to control or mitigate an accident in which the core is severely damaged.

3) Increased emphasis on reactor and plant transients."

"3. Facility Certifications

Certifications completed pursuant to Sections 55.10(a) (6) and 55.33a(4) and (5) of 10 CFR Part 55 shall be signed by the highest level of corporate management for plant operation (for example, Vice President for Operations)."

-NRC Letter dated March 28, 1980, Enclosure 1

Also see NUREG 0737

CPNPP Response

Refer to revised Section 13.2.1.1. The referenced program is consistent with 10 CFR 55 rulemaking issued after the TMI-2 event.

I.A.2.3 Administration of Training Programs

Action Plan Requirements

"Training center and facility instructors who teach systems, integrated responses, transient and simulator courses shall demonstrate their competence to NRC by successful completion of a senior operator examination."

"Instructors shall be enrolled in appropriate requalification programs to assure they are cognizant of current operating history, problems, and changes to procedures and administrative limitations."

-NRC Letter dated March 28, 1980, Enclosure 1

CPNPP Response

Refer to revised Section 13.2.1. The referenced program is consistent with 10 CFR 55 rulemaking issued after the TMI-2 event.

I.A.3 LICENSING AND REQUALIFICATION OF OPERATING PERSONNEL

OBJECTIVE:

"Upgrade the requirements and procedures for nuclear power plants operator and supervisor licensing to assure that safe and competent operators and senior operators are in charge of the

day-to-day operation of nuclear power plants. Increase the requirements for initial issuance of licenses and for license renewals and provide closer NRC monitoring of licensed activities."

-NUREG 0660, Pg. I.A.3-1

I.A.3.1 Revise Scope and Criteria for Licensing Examinations

Action Plan Requirements:

"B. NRC Examinations

1. Increase Scope of Examinations

a. A new category shall be added to the operator written examination entitled, "Principles of Heat Transfer and Fluid Mechanics."

b. A new category shall be added to the senior operator written examination entitled, "Theory of Fluids and Thermodynamics."

c. Time limites shall be imposed for completion of the written examinations:

1. Operator: 9 hours.

2. Senior Operator: 7 hours.

d. The passing grade for the written examination shall be 80% overall and 70% in each category.

e. All applicants for senior operator licenses shall be required to be administered an operating test as well as the written examination.

f. Applicants will grant permission to NRC to inform their facility management regarding the results of the examinations for purposes of enrollment in requalification programs."

-NRC Letter, dated March 28, 1980
Enclosure 1, pg. 4

2. Simulator Examinations

"Simulator examinations will be included as part of the licensee examinations."

"The administration of simulator examinations will be deferred for applicants whose facilities do not have simulators on site as of October 1, 1980. These deferred simulator examinations will be initiated by October 1, 1981."

- NUREG 0737

CPNPP Response

Refer to revised Section 13.2.1.1 . The referenced program is consistent with 10 CFR 55 rulemaking issued after the TMI-2 event.

All CPNPP senior operator cold license candidates will be prepared for an operating test as well as a written examination.

NRC will be provided with a signed release granting permission for NRC to inform CPNPP management regarding the results of the examinations for purposes of enrollment in requalification programs.

CPNPP takes the position that operations on the specified plant should be reinforced by examination at the time of licensing rather than operations on a non-identical plant. Reasoning from this position, CPNPP maintains that simulator examinations on a non-identical plant simulator should not be scheduled consecutively with the balance of the license examination. Furthermore, scheduling examinations at a remote location for an entire operating staff on a fully-booked simulator where the examination target date is not completely predictable cannot be accomplished by a cold license applicant in the narrow window of time prescribed.

I.B SUPPORT PERSONNEL

I.B.1 MANAGEMENT FOR OPERATIONS

OBJECTIVE:

"Improve licensee safety performance and ability to respond to accidents by upgrading the licensee groups responsible for radiation protection and plant operation. The areas to be upgraded include (1) staff size; (2) education and experience of staff members; (3) plant operating and emergency prodecures; (4) management awareness of and attention to safety matters; and (5) numbers and types of personnel available to respond to accidents. Licensee safety performance would further improved if (1) a full-time, dedicated, onsite safety engineering staff were established, and (2) and integrated program for the systematic review of operating experience were provided with the concurrent dissemination of information to plant personnel."

- NUREG 0660, pg. I.B.1-1

I.B.1.2 Evaluation of Organization and Management Improvements of Near – Term Operating License Applicants

Action Plan Requirements:

Each applicant for an operating license shall establish an onsite independent safety engineering group (ISEG) to perform independent reviews of plant operations.

The pricipal function of the ISEG is to examine plant operating characteristics, NRC issuances, Licensing Information Service advisories, and other appropriate sources of plant design and operating experience information that may indicate areas for improving plant safety. The ISEG is to perform independent reviews and audits of plant activities including maintenance, modifications, operating problems, and operational analysis, and aid in the establishment of programmatic requirements for plant activities. Where useful improvements can be achieved, it is expected that this group will develop and present detailed recommendations to corporate management for such things as revised procedures or equipment modifications.

Another functions of the ISEG is to maintain surveillance of plant operations and maintenance activities to provide independent verification that these activities are performed correctly and that human errors are reduced as far as practicable. ISEG will then be in a position to advise utility management on the overall quality and safety of operations. ISEG need not perform detailed audits of plant operations and shall not be responsible for sign-off functions such that it becomes involved in the operating organization.

- NUREG 0737

CPNPP Response

The principal functions and composition of the former ISEG have been distributed throughout CPNPP organizations.

Since the time of NUREG-0737 (1980) and CPNPP licensing and initial operations (1990), the CPNPP organization has continually evolved and improved. Many new plant programs and

processes have been developed and implemented (e.g., improved Corrective Action Program, System Engineering Department and related programs, a Maintenance Rule Program, individual plant department self-assessments, etc.). These improved organizational attributes overlap and/ or complement the original ISEG intended functions. Therefore it was determined that continued description of the ISEG in the FSAR was unnecessary.

I.B.2 INSPECTION OF OPERATING REACTORS

I.B.2.2 Resident Inspector at Operating Reactors

“An NRC resident inspector will be assigned to each site.”

- NUREG 0694, Pg. 26

CPNPP Response

CPNPP will provide facilities for each resident inspector as required.

I.C OPERATING PROCEDURES

OBJECTIVE:

"Improve the quality of procedures to provide greater assurance that operator and staff actions are technically correct, explicit and easily understood for normal, transient, and accident conditions. The overall content, wording, and format of procedures that affect plant operation, administration, maintenance, testing, and surveillance will be included. A principal part of this work is to improve procedures for dealing with abnormal conditions and emergencies by improving the delineation of symbols, events, and plant conditions that identify emergency or off-normal situations that confront the operators and, once identified, to assure consistency with operator training."

- NUREG-0660, pg. I.C-1

I.C.1 SHORT-TERM ACCIDENT ANALYSIS AND PROCEDURES REVISION

Action Plan Requirements:

"a. Provide the analysis, emergency procedures, and training to substantially improve operator performance during a small break loss-of-coolant accident."

"b. Provide the analysis, emergency procedure, and training needed to assure that the reactor operator can recognize and respond to conditions of inadequate core cooling."

"c. Provide the analysis, emergency procedures, and training to substantially improve operator performance during transients and accidents, including events that are caused or worsened by inappropriate operator actions."

- NUREG 0578, Pg. 12

Also see NUREG 0737.

CPNPP Response

Small break loss-of-coolant accident analyses have been performed and submitted to Staff in WCAP-9600. The report presents a comprehensive study of Westinghouse system response to small breaks. On-going efforts aimed at improving emergency operating procedure guidelines have already been discussed by Westinghouse and NRC Staff.

Inadequate core cooling is an item to be addressed, as stated in I.E. Bulletin 79-06C. Further definition of the scope of the item is needed form the NRC Staff, such as system failure and operator error assumptions to be made in the analyses. At present Westinghouse model preparation is in progress to permit response to identified action.

Westinghouse does plan to perform pre-test calculations of the LOFT tests when the necessary input information is available.

The purpose of the recommended transient and accident analysis is to provide an increase in safety by improving the performance of reactor operators during transient and accident

conditions. The primary concern is that the operator training and emergency operating procedures are based on the conservative FSAR Chapter 15 analyses. Chapter 15 should continue to be used for design basis analyses since these show the most limiting initial approach to safety limits, both core thermal and system overpressurization. What is needed to meet the intent of this section of NUREG-0578 is to show the long-term consequences using realistic assumptions (better estimate modeling) incorporating the effects of the following:

1. Operator's failure to act when required.

2. Operator's inappropriate actions during an accident.

3. Additional failures.

4. Selected system operations (e.g., re-starting of RCP's etc.)

The results of these analyses can be used to evaluate information available to the operator and the adequacy of existing procedures. Appropriate changes can then be incorporated into the existing procedures, designs, and training programs. Development of the models to incorporate such effects is in itself a long-term effort before detailed analyses can be run. Significant interaction between industry and the NRC is required to agree on the assumptions, bases, appropriate actions or misactions to be modeled, and best estimate boundary conditions. When completed, the analyses results using the better estimate modeling tools can enhance the current operator training programs by providing additional insight into the course of events the operator will likely encounter during a transient.

The Westinghouse Owners Group (WOG) will submit a detailed description of a program to comply with the requirements of item I.C.1 to the NRC in early 1981. The program will identify WOG's previous submittals to the NRC and the additional effort required to obtain full compliance with this item. After approval of the program by the NRC, CPNPP will submit to the NRC a schedule and program, based on the WOG program, for meeting the requirements of item I.C.1.

NUREG-0737 states that reviews of emergency procedures being conducted under the pilot program, item I.C.8. (NUREG-0660), will be discontinued when the long-term program item I.C.9 (NUREG-0660) is made available. Because it is anticipated that the requirements and guidelines of the long-term program will soon be available, CPNPP will comply with the long-term program rather than submitting procedures for review under the pilot monitoring program.

I.C.2 SHIFT AND RELIEF TURNOVER PROCEDURES

Action Plan Requirements:

"Review and revise plant procedures as necessary to assure that a shift turnover checklist is provided and required to be completed and signed by the on-going and off-going individuals responsible for command of operations in the control room. Supplementary checklists and shift logs should be developed for the entire operations organization, including instrument technicians, auxiliary operators, and maintenance personnel."

- NUREG 0578, Pg. 13

CPNPP Response

A procedure has been established for shift and relief turnover to provide a checklist for reactor operators and shift supervisors. The checklist for auxiliary operators, a system to evaluate the shift turnover, and the implementation of these procedures will be completed prior to fuel load.

I.C.3 SHIFT SUPERVISOR'S RESPONSIBILITIES

Action Plan Requirements:

"Review plant administrative and management procedures. Revise as necessary to assure that reactor operations command and control responsibilities and authority are properly defined. Corporate management shall revise and promptly issue an operations policy directive that emphasizes the duties, responsibilities, and authority and lines of command of the control room operators, the shift technical advisor, and the person responsible for reactor operations command in the control room (i.e., the senior reactor operator)."

- NUREG 0578, Pg. 12

CPNPP Response

Prior to OL and annually thereafter, the Senior Vice President & Principal Nuclear Officer will issue a management directive that emphasizes the primary management responsibility of the Shift Manager for safe operation of the plant under all conditions and that clearly defines his command duties.

Procedures have been established which define the responsibilities and authorities of the Shift Manager and establish lines of succession. These procedures explicitly address the NUREG concerns dealing with retaining breadth of perspective of operational conditions affecting safety and remaining in the control room under accident conditions to direct operational activities. These new provisions will be incorporated into the training program for the Shift Manager.

I.C.4 CONTROL ROOM ACCESS

Action Plan Requirements:

"Review plant emergency procedures, and revise as necessary, to assure that access to the control room under normal and accident conditions is limited to those persons necessary to the safe command and control of operations."

- NUREG 0578, Pg. 13

CPNPP Response

Administrative procedures have been written to formalize policies which allow the Shift Manager, or his designated alternate, to restrict access to the Control Room during both normal operations and emergencies. The procedures establish a clear line of authority, responsibility and succession in the Control Room in the event of an emergency.

I.C.5 PROCEDURES FOR FEEDBACK OF OPERATING EXPERIENCE TO PLANT STAFF

Action Plan Requirements:

"In accordance with Task Action Plan I.C.5, Procedures for Feedback of Operating Experience to Plant Staff (NUREG-0660), each applicant for an operating license shall prepare procedures to assure that operating information pertinent to plant safety originating both within and outside the utility organization is continually supplied to operators and other personnel and is incorporated into training and retraining programs. These procedures shall:

(1) Clearly identify organizational responsibilities for review of operating experience, the feedback of pertinent information to operators and other personnel, and the incorporation of such information into training and retraining programs;

(2) Identify administrative and technical review steps necessary in translating recommendations by the operating experience assessment group into plant actions (e.g., changes to procedures; operating orders);

(3) Identify the recipients of various categories of information from operating experience (i.e., supervisory personnel, shift technical advisors, operators, maintenance personnel, health physics technicians) or otherwise provide means through which such information can be readily related to the job functions of the recipients;

(4) Provide means to assure that affected personnel become aware of and understand information of sufficient importance that should not wait for emphasis through routine training and retraining programs;

(5) Assure that plant personnel do not routinely receive extraneous and unimportant information on operating experience in such volume that it would obscure priority information or otherwise detract from overall job performance and proficiency;

(6) Provide suitable checks to assure that conflicting or contradictory information is not conveyed to operators and other personnel until resolution is reached; and,

(7) Provide periodic internal audit to assure that the feedback program functions effectively at all levels."

- NUREG 0737

CPNPP Response

Procedures have been established to ensure that reports of industry operating experiences distributed either as INPO Event Reports or INPO SEE-IN reports, vendor technical correspondence, or as NRC Correspondence are assessed, and that applicable reports are distributed directly to appropriate station personnel, including, when appropriate, the Shift Operations Manager and the Nuclear Training Manager. For INPO Event Reports, INPO SEE-In reports and NRC Information Notices, these procedures direct recipients to develop appropriate action plans in response to the recommendations developed from assessed reports and to inform the Performance Improvement Department of their plans. The Performance Improvement

Department will monitor recipients' efforts and related developments until the problems identified and/or the concerns raised by the report processing are adequately addressed. Vendor technical correspondence is screened for operating experience by the Vendor Equipment Technical Information Program and distributed to the cognizant organization for action/information. The cognizant organization must acknowledge review of the vendor technical correspondence. NRC Bulletins and other pertinent NRC assessments of operating experience are screened by Performance Improvement and Regulatory Affairs for appropriate distribution and forwarded to the cognizant organization for action/information.

Correspondence which requires a written response or a specific action are tracked to completion by Regulatory Affairs.

Procedures have been established to provide a mechanisim for: reporting problems which occur at CPNPP, correcting the condition, evaluating the reports to identify trends, and determining what changes, if any, are required to prevent recurrence. Procedures assign responsibility for ensuring all required corrective actions are completed. Information on these problems are available to management and plant staff through various methods for dissemination of relevant information to their personnel.

Procedures have been developed in both the Operations department and the Training department to ensure that appropriate information is communicated to operations personnel and incorporated into training programs. These procedures include mechanisms for timely dissemination of information when circumstances warrant. The Shift Operations Manager has the responsibility of screening the available information to ensure both that operations personnel are not burdened with extraneous and unimportant information, and that they do not receive conflicting or contradictory information.

The Performance Improvement Department will distribute operating experience related information to appropriate licensed and other interested personnel. The Performance Improvement Department will ensure that all appropriate personnel remain cognizant of recent industry and station operating experience.

I.C.6 PROCEDURES FOR VERIFYING CORRECT PERFORMANCE OF OPERATING ACTIVITIES

Action Plan Requirements:

"It is required (from NUREG-0660) that licensees' procedures be reviewed and revised, as necessary, to assure that an effective system of verifying and correct performance of operating activities is provided as a means of reducing human errors and improving the quality of normal operations. This will reduce the frequency of occurrence of situations that could result in or contribute to accidents. Such a verification system may include automatic system status monitoring, human verification of operations and maintenance activities independent of the people performing the activity (see NUREG-0585, Recommendation 5), or both.

Implementation of automatic status monitoring if required will reduce the extent of human verification of operations and maintenance activities but will not eliminate the need for such verification in all instances. The procedures adopted by the licensees may consist of two phases – one before and one after installation of automatic status monitoring equipment, if required, in accordance with item I.D.3."

- NUREG 0737

CPNPP Response

Procedures will be established which designate the responsibilities and authorities of personnel associated with the control of equipment. The procedures will address the second, independent verification of proper tagging and the return-to-service of equipment by qualified operators. These procedures will be implemented prior to fuel load.

I.C.7 NSSS VENDOR REVIEW OF PROCEDURES

Action Plan Requirements:

"Obtain nuclear steam supply system (NSSS) vendor review of low-power testing procedures to further verify their adequacy."

- NUREG 0694, Pg. 14

"Obtain NSSS vendor review of power-ascension test and emergency procedures to further verify their adequacy."

- NUREG 0694, Pg. 20

CPNPP Response

CPNPP shall have Westinghouse review the low-power testing procedures prior to fuel loading and the power-ascension and emergency procedures prior to full-power operation.

I.C.8 PILOT MONITORING OF SELECTED EMERGENCY PROCEDURES FOR NTOL APPLICANTS

Action Plan Requirements:

"Correct emergency procedures, as necessary, based on the NRC audit of selected plant emergency operating procedures (e.g., small-break LOCA, loss of feedwater, restart of engineered safety features following a loss of ac power, steam-line break, or steam-generator tube rupture)."

- NUREG 0694, Pg. 21

Also see NUREG-0737.

CPNPP Response

NUREG-0737 states that reviews of emergency procedures being conducted under the pilot monitoring program, item I.C.8. (NUREG-0660), will be discontinued when the long-term program item I.C.9 (NUREG-0660) is made available. Because it is anticipated that the requirements and guidelines of the long-term program will soon be available, CPNPP will comply with the long-term program rather than submitting procedures for review under the pilot monitoring program.

I.D CONTROL ROOM DESIGN

OBJECTIVE:

"Improve the ability of nuclear power plant control room operators to prevent accidents or cope with accidents if they occur by improving the information provided to them."

- NUREG 0660, Pg. I.D-1

I.D.1 CONTROL ROOM DESIGN REVIEW

Action Plan Requirements:

"In accordance with Task Action Plan I.D.1, Control Room Design Reviews (NUREG-0660), all licensees and applicants for operating licenses will be required to conduct a detailed control-room design review to identify and correct design deficiencies. This detailed control-room design review is expected to take about a year. Therefore, the Office of Nuclear Reactor (NRR) requires that those applicants for operating licenses who are unable to complete this review prior to issuance of a license make preliminary assessments of their control rooms to identify significant human factors and instrumentation problems and establish a schedule approved by NRC for correcting deficiencies. These applicants will be required to complete the more detailed control room reviews on the same schedule as licensees with operating plants."

- NUREG 0737

CPNPP Response

The Detailed Control Room Design Review (DCRDR) has been completed in accordance with NUREG-0700 and the reports submitted to the NRC. Onsite audits/reviews have been conducted by the NRC. Implementation of the required design changes has been completed. A final environmental survey was conducted for Unit 1 when construction and modifications were completed. Based on the results of the environmental surveys, Unit 2 control boards were compared to Unit 1 control boards to assess any design differences. Supplements to the DCRDR were submitted prior to fuel loads for Unit 1 and Unit 2 respectively.

Procedures have been developed to formalize the ongoing Human Factors Engineering (HFE) program at CPNPP. The major elements of the HFE program include:

a) HFE review of control room design changes which includes the following:

   1. HFE design review of existing "legacy" control room equipment/systems per guidelines contained in NUREG-0700, Revision 0 [1981].

   2. HFE design review of new and replacement plant computer and plant digital control systems per guidelines contained in NUREG-0700, Revision 2 [2002].

b) Multi-discipline team for the assessment, disposition and verification of Training, Operations and Engineering HFE concerns

c) Site specific HFE design guide

d) Function and task analysis of Emergency Response Guidelines (ERGs) and the comparison with control room capabilities

e) Computer Aided Design (CAD) detailed control board layout drawings

f) Standard abbreviations and acronyms for control room labels and procedures

The DCRDR and the ongoing HFE program were audited by the NRC in January, 1989.

I.D.2 PLANT SAFETY PARAMETER DISPLAY CONSOLE

Action Plan Requirements:

"In accordance with Task Action Plan 1.D.2, Plant Safety Parameter Display Console (NUREG-0660), each applicant and license shall install a safety parameter display system (SPDS) that will display to operating personnel a minimum set of parameters which define the safety status of the plant. This can be attained through continuous indication of direct and derived variables as necessary to assess plant safety status."

- NUREG 0737

Also see NRC Letter dated August 1, 1980.

CPNPP Response

A plant safety parameter display console has provided for CPNPP to assess plant safety status. This system is designed in accordance with NUREG-0696 and NUREG-0737 Supplement 1.

I.G PREOPERATIONAL AND LOW POWER TESTING

OBJECTIVE:

"Increase the capability of the shift crews to operate facilities in a safe and competent manner by assuring that training for plant changes and off-normal events if conducted. Near-term operating license facilities will be required to develop and implement intensified training exercises during the low-power testing programs. This may involve the repetition of startup test on different shifts for training purposes. Based on experiences form the near-term operating license facilities, requirements may be applied to other new facilities or incorporated into the plant drill requirement (Item I.A.2.5). Review comprehensiveness of test programs."

- NUREG 0660, Pg. I.G-1

I.G.1 TRAINING REQUIREMENTS

Action Plan Requirements:

"Define and commit to a special low-power testing program approved by NRG to be conducted at power levels no greater than 5 percent for the purposes of providing meaningful technical information beyond that obtained in the normal startup test program and to provide supplemental training."

- NUREG 0694, Pg. 15

"Supplement operator training by completing the special low-power test program. Test may be observed by other shifts or repeated on other shifts to provide training to the operators."

- NUREG 0694, Pg. 21

CPNPP Response

Refer to revised section 13.2.1.1. The referenced program is consistent with 10 CFR 55 rulemaking issued after the TMI-2 event.

Testing to demonstrate the length of time required to stabilize natural circulation, core flow distribution, ability to establish and maintain natural circulation with or without onsite and offsite power, the ability to uniformly borate and cool down to hot shutdown conditions using natural circulation, and subcooling monitor performance have been performed at the Sequoyah 1 and Salem 2 facilities, which are comparable prototype plants, and will not be performed at CPNPP.

A description of the natural circulation demonstrations that are to be conducted as part of the training program during the low-power test program will be included in the CPNPP FSAR (Chapter 14 - Initial Test Program).

II SITING AND DESIGN

II.B CONSIDERATION OF DEGRADED OR MELTED CORES IN SAFETY REVIEW

OBJECTIVE:

"Enhance public safety and reduce individual and societal risk by developing and implementing a phased program to include in safety reviews, consideration of core degradation and melting beyond the design basis. The program phases are (1) short- and medium-term actions for scoping and implementation; (2) added requirements for high population density sites; (3) research programs and design studies to develop additional needed information; and (4) a rulemaking proceeding to establish long-term policy, goals, and requirements related to accidents involving core damage greater than the present design basis."

- NUREG 0660, Pg. II.B-1

II.B.1 REACTOR COOLANT SYSTEM VENTS

Action Plan Requirements:

"Each applicant and licensee shall install reactor coolant system (RCS) and reactor vessel head point vents remotely operated from the control room. Although the purpose of the system is to vent noncondensible gases from the RCS which may inhibit core cooling during natural circulation, the vents must not lead to an unacceptable increase in the probability of a loss-of-coolant accident (LOCA) or a challenge to containment integrity. Since these vents form a part of the reactor coolant pressure boundary, the design of the vents shall conform to the requirements of Appendix A to 10 CFR Part 50, "General Design Criteria." The vent system shall be designed with sufficient redundancy that assures a low probability of inadvertent or irreversible actuation.

"Each licensee shall provide the following information concerning the design and operation of the high point vent system:*

(1) Submit a description of the design, location, size, and power supply for the vent system along with results of analyses for loss-of-coolant accidents initiated by a break in the vent pipe. The results of the analyses should demonstrate compliance with the acceptance criteria of 10 CFR 50.46.

(2) Submit procedures and supporting analysis for operator use of the vents that also include the information available to the operator for initiating or terminating vent usage."

"*It was the intent of the October 30, 1979 letter to delete the requirement to meet the criteria of 10 CFR 50.44 and SRP 6.2.5 for beyond-design-basis events. The analysis requirements of Position 2 in the September 13, 1979 letter are therefore unnecessary."

CPNPP Response

CPNPP has the capability to remotely vent gases from the reactor vessel head and pressurizer vapor space during a post-accident situation where large quantities of non-condensible gas may collect.

Venting of the reactor vessel head is provided via a line isolated by two one-inch valves in series which vents directly to containment. The venting of the pressurizer vapor space is provided in the same manner. The valves are fail-closed solenoid valves which are environmentally and seismically qualified. The head vent valves are powered by Train A 1E power and the pressurizer vent valves are powered by Train B 1E power.

These vents are operable from the Control Room and positive indication of valve position is also provided in the Control Room.

Procedures will be developed to address the use of the Reactor Coolant System vents. The procedures will address information available to the operator and instructions for initiating or terminating vent usage. This will be implemented upon staff approval.

Details of the design and supporting information required by NUREG- 0737 is provided in Section 1.7, 3.10N, 3.11N, 3A, 5.1 and 17A.

II.B.2 PLANT SHIELDING TO PROVIDE ACCESS TO VITAL AREAS AND PROTECT SAFETY EQUIPMENT FOR POSTACCIDENT OPERATION

Action Plan Requirements:

“With the assumption of a postaccident release of radioactivity equivalent to that described in Regulatory Guides 1.3 and 1.4 (i.e., the equivalent of 50% of the core radioiodine, 100% of the core noble gas inventory, and 1% of the core solids are contained in the primary coolant), each licensee shall perform a radiation and shielding-design review of the spaces around systems that may, as a result of an accident, contain highly radioactive materials. The design review should identify the location of vital areas and equipment, such as the control room, radwaste control stations, emergency power supplies, motor control centers, and instrument areas, in which personnel occupancy may be unduly limited or safety equipment may be unduly degraded by the radiation fields during postaccident operations of these systems.”

“Each licensee shall provide for adequate access to vital areas and protection of safety equipment by design changes, increased permanent or temporary shielding, or postaccident procedural controls. The design review shall determine which types of corrective actions are needed for vital areas throughout the facility.”

CPNPP Response

A design review of CPNPP radiation and shielding for post-accident operations has been performed in accordance with the guidelines of NUREG-0737. The plant shielding review is a non-nuclear safety-related study, and is not subject to Quality Assurance. The review considered the potential radiation exposure to operators in vital areas and to Class 1E equipment. The following section describes the assumptions and methodology employed in the review and a summary of the results. Any design changes resulting from the study are covered by the

QA requirements for the items being changed. Any additions or modifications to shielding during operations are subject to an appropriate Operations QA Program. The results of the review of radiation qualification of Class 1E equipment will be included in FSAR Section 3.11.

II.B.2.1 Source Terms

The source terms used in this evaluation of shielding are based on the postulated post-accident release of radioactivity equivalent to that described in Regulatory Guide 1.4 and TID-14844.

The reactor core inventory of radioisotopes is derived from the assumptions listed in Table 12.2-24.

The source terms and corresponding systems employed in the evaluation are described in Section 12.2.1.3. The specific subsections are 12.2.1.3.3 for nondepressurized primary coolant, 12.2.1.3.4 for depressurized containment sump water, 12.2.1.3.5 for Process Sampling System sources, and 12.2.1.3.1 for containment atmosphere. These source terms are based on the core activity release fractions identified in Table 12.2-16.

II.B.2.2 System Review

After establishing the source terms noted above, the systems which may contain highly radioactive materials in a post-accident situation have been evaluated. The specific systems reviewed are described in the following subsections.

II.B.2.2.1 Containment

Direct radiation penetrating through the containment walls and radiation streaming through penetrations was based on the source term discussed in Section 12.2.1.3.1. Radiation streaming causes a significant dose rate outside the containment equipment hatch in a field within ″ 25° from the hatch centerline. The dose rate changes with time and distance. Immediately following a LOCA the dose rate is calculated to be about 44 rem per hour at a point 30 feet from the containment surface and about 4 rem per hour at 240 feet. These dose rates decrease to less than 2 rem per hour and 0.06 rem per hour respectively at 24 hours after the accident.

II.B.2.2.2 Emergency Core Cooling System

Plant shielding has been evaluated considering the Emergency Core Cooling System (ECCS) to be operating in the recirculation mode. The residual heat removal pumps take suction from the containment sump, and the safety injection pumps and centrifugal charging pumps take suction from the residual heat removal pump discharge.

Prior to the start of recirculation, the ECCS will contain water from the refueling water storage tank. Although recirculation operation is not initiated until approximately 10 minutes to several hours after the start of an accident the shielding review has assumed that at the beginning of the accident the ECCS contains the source terms described in Section 12.2.1.3.4.

II.B.2.2.3 Residual Heat Removal System

Plant shielding has been evaluated considering the Residual Heat Removal System (RHRS) contains the source terms specified in Section 12.2.1.3.3 for nondepressurized LOCA conditions, or the source terms specified in Section 12.2.1.3.4 for depressurized LOCA conditions as appropriate.

II.B.2.2.4 Containment Spray System

Plant shielding has been evaluated considering the Containment Spray System (CSS) to be operating in the recirculation mode. Prior to the start of recirculation, the CSS will contain water from the refueling water storage tank. Although CSS recirculation operation is not initiated until approximately 15 minutes to several hours after an accident (if required), the shielding evaluation has assumed that at the beginning of the accident the CSS contains the source terms described in Section 12.2.1.3.4.

II.B.2.2.5 Chemical And Volume Control System

A portion of the chemical and volume control system (CVCS), namely the charging pumps and the connecting piping to the RHRS and safety injection system, may contain post-accident sources during depressurized LOCA conditions. Source terms in this portion of the CVCS are described in Section 12.2.1.3.4. The remainder of the CVCS is not expected to become highly radioactive in a post-accident situation because the letdown system is automatically isolated and is not required for accident mitigation.

II.B.2.2.6 Gas Waste Processing System

The Gas Waste Processing System (GWPS) is not expected to contain highly radioactive material generated following an accident since the system is automatically isolated from components that do contain the radioactive material, and it is not required to mitigate an accident. Therefore, the system has been excluded as a potential source of highly radioactive material following a LOCA.

II.B.2.2.7 Post-Accident Sampling System

The Process Sampling System (PSS) is used for post-accident sampling.

Plant shielding has been evaluated considering PSS components and sample lines containing liquid sources as described in Section 12.2.1.3.3 or 12.2.1.3.4.

II.B.2.3 Shielding Methods

Evaluation of plant shielding for equipment qualification dose evaluations following an accident includes direct radiation from the containment, and radiation from piping and components of systems discussed in Section II.B.2.2, as appropriate. Direct radiation through shield walls and streaming and scattered radiation through penetrations were considered. Direct radiation and streaming radiation dose rates for the post-accident shielding evaluation were calculated by point-kernel shielding codes. Exponential attenuation through the shields with dose build-up factors corresponding to the number of mean free paths in the shield were considered. The scattered radiation dose rate from surrounding surfaces was determined by the albedo method.

Gamma energy levels of the radiation source are typically divided into eight or ten energy groups for the analysis.

II.B.2.4 Design Review

The plant shielding design review has identified the radiation exposure rates in vital areas requiring personnel access following a LOCA. The vital areas of the plant which may need periodic access after a LOCA for performing manual operations to mitigate the consequences of the accident are described in Table II.B.2-4. This table also presents the operator path or route numbers, the time after LOCA when access to the area is required, and the calculated radiation dose that may be received by the operator during the performance of the assigned task.

Plant drawings have also been developed to illustrate the post LOCA access routes to the vital areas. These drawings are presented in Figures II.B.2-25 through II.B.2-86. Radiation dose rates between various points of the operator path, the time spent between consecutive points and the path or route number are shown in Table II.B.2-5 and II.B.2-6.

The Control Room Complex and the Technical Support Center (TSC) are vital areas requiring full-time occupancy during the course of an accident. The integrated dose for these areas is less than 5 rem whole-body, or equivalent, for the duration of the accident in accordance with GDC 19. Further details pertaining to the Control Room and TSC dose analyses are provided in Section 15.6.5.4.4.

Motor control centers (MCCs) are not considered to be vital areas for purpose of this review, since single failure criteria were assumed; and a single failure would not prohibit the ability of the MCCs' functions to be performed from the control room.

Access to radwaste control panels is not considered to be vital, since the safety injection signal during postulated DBA conditions will isolate reactor coolant letdown. Therefore, no highly radioactive post-accident fluids will be present in the radwaste systems.

II.B.2.5 Radiation Qualification of Class 1E Equipment

The post-accident radiation exposure to Class 1E equipment located outside and inside containment has been evaluated for post-accident sources postulated to exist following a LOCA. The source terms for equipment located outside containment are described in Section 12.2.1.3.3, 12.2.1.3.4, or 12.2.1.3.5, as applicable. For Class 1E equipment inside containment, the larger dose resulting from sources described in either Section 12.2.1.3.3 or Sections 12.2.1.3.1 and 12.2.1.3.4 were utilized. Equipment dose evaluations for Class 1E equipment inside and outside containment are based on the guidelines of NUREG 0588 and Regulatory Guide 1.89. These dose evaluations consider both gamma and beta radiation, as appropriate for post-accident conditions, and include contributions from normal operations. The calculated post-accident radiation dose values for Class 1E equipment are included in FSAR Appendix 3A.

II.B.3 POST-ACCIDENT SAMPLING

Action Plan Requirements:

"A design and operational review of the reactor coolant and containment atmosphere sampling line systems shall be performed to determine the capability of personnel to promptly obtain (less

than 1 hour) a sample under accident conditions without incurring a radiation exposure to any individual in excess of 3 and 18-3/4 rem to the whole body or extremities, respectively. Accident conditions should assume a Regulatory Guide 1.3 or 1.4 release of fission products. If the review indicates that personnel could not promptly and safely obtain the samples, additional design features or shielding should be provided to meet criteria.

"A design and operational review of the radiological spectrum analysis facilities shall be performed to determine the capability to promptly quantify (in less than 2 hours) certain radionuclides that are indicators of the degree of core damage. Such radionuclides are noble gases (which indicate cladding failure), iodines and cesiums (which indicate high fuel temperatures), and nonvolatile isotopes (which indicate fuel melting). The initial reactor coolant spectrum should correspond to a Regulatory Guide 1.3 or 1.4 release. The review should also consider the effects of direct radiation from piping and components in the auxiliary building and possible contamination and direct radiation from airborne effluents. If the review indicates that the analyses required cannot be performed in a prompt manner with existing equipment, then design modifications or equipment procurement shall be undertaken to meet the criteria.

"In addition to the radiological analyses, certain chemical analyses are necessary for monitoring reactor conditions. Procedures shall be provided to perform boron and chloride chemical analyses assuming a highly radioactive initial sample (Regulatory Guide 1.3 or 1.4 source term). Both analyses shall be capable of being completed promptly (i.e., the boron sample analysis within an hour and the chloride sample analysis within a shift)."

CPNPP Response

II.B.3.1 General Description

FSAR Section 9.3.2 describes the process sampling system installed in CPNPP. This system was designed for the capability of obtaining samples during normal operating conditions. During postulated accident conditions, radiation levels would be significantly increased.

The Post-Accident Sampling System (PASS) is comprised of two independent subsystems; the Reactor Coolant PASS (RC PASS) and the Containment Air PASS (CA PASS). Figures II.B.3-1 and Flow Diagram M1(2)-301-A illustrate the basic system flow diagrams for the RC PASS and CA PASS respectively.

II.B.3.2 Design Criteria and Functional Requirements

The requirements of NUREG-0737, II.B.3 have been eliminated for CPNPP in accordance with License Amendment 91.

II.B.3.3 PASS Equipment

As stated above, the CPNPP PASS is comprised of two independent subsystems, the Reactor Coolant PASS (RC PASS) and the Containment Air (CA PASS). A discussion of the major components of each of these subsystems is provided below.

II.B.3.3.1 Reactor Coolant PASS

The RC PASS, as shown in Figure II.B.3-1, includes the following major components:

- RC PASS Sample Module
- RC PASS Remote Operating Module
- RC PASS Flush and Diversion Manifold
- RC PASS Auxiliary Module
- RC PASS Flush Module
- RC PASS Sample Cooler

The RC PASS is in layup.

II.B.3.3.2 Containment Air PASS

The Containment Air PASS (CA PASS) will be used to obtain micro-volume samples of the containment atmosphere. The CA PASS, as shown in Flow Diagram

M1(2)-301-A, includes the following major components:

- CA PASS Sample Module
- CA PASS Remote Operating Module
- CA PASS Sample Diversion Valve

The CA PASS is in layup.

II.B.3.3.3 PASS Isolation Valve Control

II.B.3.3.3.1 PASS Isolation Valve Control Panel

The PASS Isolation Valve Control Panel (PIVCP) is a Class 1E, Seismic Category I electrical control panel. It is located in the cable spreading room, a low radiation area.

The PIVCP is provided to permit control for all isolation valves associated with both the RC PASS and the CA PASS. The bypass function of the PIVCP has been disabled.

The PIVCP has control switches for the operation of twelve (12) isolation valves. Three (3) of these valves can also be controlled during normal operation of the Sample Valve Control Panel (SVCP).

Train oriented selector switches are provided at the PIVCP to select controls at the SVCP or PIVCP. The remaining nine (9) valves are controlled exclusively at the PIVCP.

The PIVCP is under direct administrative control of the control room operator. Train oriented control switches configured “CLOSE-LOCAL” are provided in the control room.

Placing these switches in the “LOCAL” position permits operation of the 12 isolation valves from the PIVCP.

II.B.3.3.3.2 Instrument Air to Containment Isolation Valve Control

Instrument air must be available for operation of the PSS Isolation Valves. Instrument air to Containment valve HV-3487 is isolated by a Containment Isolation Phase A signal. This valve must be opened to admit instrument air to tubing run inside containment in order to obtain a sample from RCS.

Opening valve HV-3487 is accomplished by operating the control switch for this valve on Main Control panel CB-01 to the OPEN position. This is a spring-return position in which the switch must be manually held to over-ride the Containment Isolation signal. Releasing the switch will cause the valve to close if the Containment Isolation signal is still present. This operation is in accordance with FSAR Section 7.3.1.1.4.2 Containment Isolation System.

Operating pressure for Instrument air is greater than the maximum pressure in Containment following an accident. The volume of Containment is so great that the capacity and use of the Instrument Air system will not significantly increase Containment pressure. A check valve inside Containment will close if the Containment pressure is greater than the Instrument Air system pressure. Since it meets containment isolation requirements and does not bring reactor coolant or containment atmosphere out of containment post-accident, instrument air is not an isolated auxiliary system (e.g. CVCS letdown) and may be used for this function.

II.B.4 TRAINING FOR MITIGATING CORE DAMAGE

Action Plan Requirements:

“A program is to be developed to ensure that all operating personnel are training in the use of installed plant systems to control or mitigate an accident in which the core is severely damaged. The training program should include the following topics.”

"1. Incore Instrumentation

a. Use of fixed or movable incore detectors to determine extent of core damage and geometry changes.

b. Use of thermocouples in determining peak temperatures; methods for extended range readings; methods for direct readings at terminal junctions.

c. Methods for calling up (printing) incore data from the plant computer.”

"2. Excore Nuclear Instrumentation (NIS)

a. Use of NIS for determination of void formation; void location basis for NIS response as a function of core temperatures and density changes.”

"3. Vital Instrumentation

a. Instrumentation response in an accident environment; failure sequence (time to failure, method of failure); indication reliability (actual vs indicated level).

b. Alternative methods for measuring flows, pressures, levels, and temperatures.

1) Determination of pressurizer level if all level transmitters fail.

2) Determination of letdown flow with a clogged filter (low flow).

3) Determination of other Reactor Coolant System parameters if the primary method of measurement has failed."

"4. Primary Chemistry

a. Expected chemistry results with severe core damage; consequences of transferring small quantities of liquid outside containment; importance of using leak tight systems.

b. Expected isotopic breakdown for core damage; for clad damage.

c. Corrosion effects of extended immersion in primary water; time to failure."

"5. Radiation Monitoring

a. Response of Process and Area Monitors to severe damages; behavior of detectors when saturated; method for detecting radiation readings by direct measurement at detector output (overranged detector); expected accuracy of detectors at different locations; use of detectors to determine extent of core damage.

b. Methods of determining dose rate inside containment from measurements taken outside containment."

"6. Gas Generation

a. Methods of H_2 generation during an accident; other sources of gas (Xe, Ke); techniques for venting or disposal of non-condensibles.

b. H_2 flammability and explosive limit; sources of 0_2 in containment or Reactor Coolant System.

- NRC Letter dated March 28, 1980, ENCLOSURE 3

"Complete the training of all operating personnel in the use of installed systems to monitor and control accidents in which the core may be severely damaged."

- NUREG 0694, Pg. 22

Also see NUREG 0737

CPNPP Response

Refer to revised sections 13.2.1.1 and 13.2.1.2. The referenced program is consistent with 10 CFR 55 rulemaking issued after the TMI-2 event.

				UNIT 1		UNIT 2	
			Time After LOCA (hrs)		Operator Dose[7]		Operator Dose[7]
	Vital Access Area	Description of Task[1]	When Access is Required	Route No.	(rem)	Route No.	(rem)
20.	Rooms 108A and 108B	Manually isolate steam supply to the AFWPT	7.0	20 Fig. II.B.2-42.4	4.0[10]	20 Fig. II.B.2-85 Fig. II.B.2-86	4.1[10]

Notes:

(1) It is assumed that each task is performed by one operator (except for Task 20).

(2) This is the maximum dose which occurs due to buildup on ESF filters at 168 hours after LOCA.

(3) These tasks may have to be repeated several times and more than one operator may be needed.

(4) Tasks No. 7 and 8 may be performed by the same operator.

(5) Task Nos. 10 and 11 may be performed by the same operator.

(6) This is the maximum dose which occurs due to buildup on Control Room pressurization filters and intake air inducting upstream of the filters at 8 hours after LOCA.

(7) Values listed represent total accumulated radiation dose to the whole body and whole body dose = extremity dose, unless separate values are noted by WB (Whole Body) or EX (Extremity). Values include all applicable dose components (e.g., task standby/briefing, en route transit, task performance, handling of radioactive materials.)

(8) Although tank is not required to be filled for one week, operators may choose to begin filling the tank after 3 days.

(9) This is the maximum dose which assumes access plate removal and replacement for each tanker truck delivery. In addition, one operator is assumed to perform the task for all deliveries.

(10) Two operators are required to perform this Task. Access is required to each room, 108A and 108B, (one separate operator per room). Dose reflects operator dose to either room.

TABLE II.B.3-1
DELETED

II.D REACTOR COOLANT SYSTEM RELIEF AND SAFETY VALVES

OBJECTIVE:

"Demonstrate by testing and analysis that the relief and safety valves, block valves and associated piping in the reactor coolant system are qualified for the full range of operating and accident conditions. Anticipated transients without scram (ATWS) may be considered in later phases of the test program. In addition, design changes or modifications will be made that are necessary to provide positive indication of valve position."

- NUREG 0660, Pg II.D-1

II.D.1 TESTING REQUIREMENTS

Action Plan Requirements:

"Pressurized-water reactor and boiling-water reactor licensees and applicants shall conduct testing to qualify the reactor coolant system relief and safety valves under expected operating conditions for design-basis transients and accidents."

CPNPP Response

CPNPP participated fully in the EPRI Safety and Relief Valve Test Program to demonstrate acceptable valve operability under expected flow conditions. Table II.D.1-1 key plant parameters pertaining to the pressurizer safety, relief, and PORV block valves. Also see Section 5.4.13 for additional details about the safety and relief valves. Valves identical to those installed at CPNPP were tested in the EPRI test program as documented in Reference 1. Block valves tested are documented in Reference 2. Inlet fluid conditions for the tests adequately envelope those expected at CPNPP as documented in Reference 3 and 8. Justification that the actual valve test conditions adequately represent anticipated plant conditions is provided in Reference 4, Sections 3.7 and 4.7 for relief and safety valves respectively. Test results for the CPNPP-representative safety and block valves are summarized in Reference 5, Sections 3.5 and 4.6 respectively.

A. The CPNPP safety valve inlet piping configuration is shorter than that employed in the tests. However, the test conditions report (Reference 4, Section 4.7), states that only the long inlet piping configuration was tested because, "…the operability of such valves with a shorter inlet is expected to be as good or better than that observed with the test configuration." Safety valve ring settings for CPNPP are comparable to the "reference" ring settings of the following tests: 929, 931a, 932, 1406, 1411, 1415, and 1419. Further discussion of the inlet piping and valve ring settings comparison with the EPRI Tests is provided in Reference 8.

   Expected valve discharge back pressure for CPNPP was modeled by Continuum Dynamics for EPRI and the results are presented in Reference 6, page 3-8. The calculated back pressure of 291 psi is well below that of the referenced 900-series of EPRI tests (650 psi) and only moderately above the 245 psi of the 1400-series of tests.

   The relief valve tests results (NP-2628-LD, Section 4.6), reflect acceptable operation in both the Marshall Steam Station tests and the Wyle Phase III tests.

Based upon the above indicated references to the appropriate reports produced in support of EPRI Project V102, the pressurizer safety and relief valves, as installed at CPNPP, were adequately represented by the previously referenced tests. Westinghouse, in Reference 7, concluded that those same tests adequately demonstrated acceptable performance of the tested safety valves for pressurizer relief at CPNPP.

Reanalysis of the CPNPP Unit 1 pressurizer safety and relief valve piping determined it to be adequate provided a loop seal temperature profile similar to that produced in EPRI Test 917 is maintained. Consequently, the safety valve loop seals will be insulated to maintain the referenced or hotter temperature profile. The calculated piping support loads have been incorporated into a reanalysis of the existing piping supports. Based on the EPRI test temperature profile and Westinghouse recommendation, since the presence of insulation on the upstream piping, which slopes to the valve, would prevent heat transfer from the piping and thus promote flashing of the liquid into steam, no insulation is installed upstream of the PORVs. A water seal is maintained at the PORVs via the sloped piping.

B. Block Valves - A small number of block valves, including the type and model used for CPNPP, were tested at the Marshall Steam Station Test Facility. After modifications to the valve operator, the valve successfully closed under high flow and high differential pressure conditions. Sufficient data was gathered to determine the modifications required to assure correct valve operation under all fluid conditions.

Subsequently, in response to IE Bulletin 81-02, CPNPP has modified the PORV block valves by changing the operator gear ratio to guarantee adequate thrust capability and by rewiring the operator for limit closing control.

Additional block valve tests are not necessary because:

1. The operability of block valves is not a safety issue. Plant procedures provide methods for safely shutting down in the event of a small break LOCA.

2. Results of block valve tests performed at the Marshall Station have provided sufficient information to address valve operability.

3. The CPNPP PORV was demonstrated to perform well over a wide range of operating and accident conditions during the EPRI relief valve testing.

4. The probability of a relief valve failure to perform its intended function is low and on the same magnitude as other [[b]] break LOCA initiators. Operability of the associated block valve does not increase the probability of a small break LOCA.

C. ATWS Testing - Although not specifically addressed by the valve testing program, the results provide most of the information necessary to address ATWS events (i.e., relief capability at high pressure).

D. For additional information on CPNPP response to this item, see References 8 and 9.

II.D.3 RELIEF AND SAFETY VALVE POSITION INDICATION

Action Plan Requirements:

"Reactor coolant system relief and safety valves shall be provided with a positive indication in the control room derived from a reliable valve-position detection device or a reliable indication of flow in the discharge pipe."

- NUREG 0737

CPNPP Response

The pressurizer PORVs have both open and close limit switches with control indicating lights mounted at their respective control switches on the main control board. The limit switches are snap acting, positive throw switches mounted on the valve yokes. They are operated by the actual valve stem motion.

The pressurizer safety valves will be equipped with Reed type valve position indicating switches with indicating lights on the main control boards. Opening of either pressurizer PORVs or safety valves will alarm in the Control Room.

Procedures will be developed/revised to address the RCS relief valve and safety valve indications. The use of this equipment will be integrated into the operator training. This will be implemented by fuel load.

These valve position indicators shall be seismically and environmentally qualified in accordance with IEEE Stds 323-1974 and 344-1975. The indicators shall be qualified and installed prior to fuel load.

II.E SYSTEM DESIGN

II.E.1 AUXILIARY FEEDWATER SYSTEM

OBJECTIVE:

"Improve the reliability of the auxiliary feedwater system (AFWS)."

- NUREG 0660, Pg. II.E.1-1

II.E.1.1 Auxiliary Feedwater System Evaluation

Action Plan Requirements:

"The Office of Nuclear Reactor Regulation is requiring reevaluation of the auxiliary feedwater (AFWS) systems for all PWR operating plant licensees and operating license applications. This action includes:

1. Perform a simplified AFW system reliability analysis that uses event-tree and fault-tree logic techniques to determine the potential for AFW system failure under various loss-of-main-feedwater-transient conditions. Particular emphasis is given to determining potential failures that could result from human errors, common causes, single-point vulnerabilities, and test and maintenance outages:

2. Perform a deterministic review of the AFW system using the acceptance criteria of Standard Review Plan

3. Reevaluate the AFW system flowrate design bases and criteria."

- NUREG 0737

4. Based on the analyses performed modify the AFWS, as necessary.

- NUREG 0694, Pg. 22

Also see NRC Letter From D. F. Ross, Jr., dated March 10, 1980.

CPNPP Response

1. The Applicant has performed a simplified Auxiliary Feedwater system reliability analysis similar in method to that described in Appendix III to NUREG-0611. The evaluation is a non-nuclear safety-related study, and is not subject to Quality Assurance. The results of this analysis presented below were prepared in response to the NRC Letter dated March 10, 1980.

   A. System Description

      A complete description of the Auxiliary Feedwater System is in Section 10.4.9. The Auxiliary Feedwater System is designed to provide a supply of high-pressure feedwater to the secondary side of the steam generators for reactor coolant heat

removal following a loss of normal feedwater. The system is comprised of two electric motor-driven pumps and a third turbine-driven pump. All three pumps draw suction from the Nuclear Safety Class 3 Condensate Storage Tanks. A single line supplies water through a common locked-open valve to the suction of the motor-driven pumps, and a second line supplies water to the suction of the turbine-driven pump. The motor-driven pumps normally feed two steam generators each. The turbine-driven pump discharge line branches into four separate lines each feeding one steam generator. The actuation of the Auxiliary Feedwater System following an accident is automatic. A simplified system flow diagram is shown in Figure II.E.1.1-1.

B. Testing

The Auxiliary Feedwater System testing is controlled by the Surveillance Requirements in the CPNPP Technical Specifications.

C. Technical Specification

See Testing above.

D. Reliability Evaluation Results

The results of the reliability evaluations are presented below for the following three events: loss of main feedwater (MFW) with offsite power available, loss of MWF and loss of offsite AC, and loss of feedwater and loss of all AC.

i. Loss of MFW with Offsite Power Available

The simplified fault tree for this transient is shown in Figure II.E.1.1-2 (Sheet 1). The reliability analysis of the Auxiliary Feedwater System based on this event did not identify any single failures that would result in insufficient auxiliary feedwater flow. One double failure was identified. This failure is the result of the closure or blocking of each of the valves in the two supply lines from the condensate storage tank. This double failure is the dominant failure mode.

ii. Loss of MFW and Loss of Offsite AC

The simplified fault tree for this transient is shown in Figure II.E.1.1-2 (Sheet 2). This accident differs from the above only In that the power for the motor driven pumps will come from the diesel generators. To determine what effect this has on overall Auxiliary Feedwater System reliability, the quantified fault tree was expressed as a function of diesel generator reliability. As expected, if the diesels have high reliability, the system reliability is the same as the “loss of feed” event and if the diesels have no reliability, the system reliability is the same as the “loss of feed and the loss of all AC” in the event offsite power is lost. For a diesel generator failure probability as high as .03 the dominant failure mode remains the same as the “loss of feed” event.

iii. Loss of Feedwater and Loss of All AC

The simplified fault tree for this transient is shown in Figure II.E.1.1-2 (Sheet 3). If all AC power is lost, there is only one steam-driven Auxiliary Feedwater pump for this train. The reliability analysis indicates that the dominant failure mode is the steam driven train being out for test or maintenance.

E. Principal Dependencies Identified

The principal dependency found in this analysis was the failure of all trains due to closure of the manual valves in the two supply lines from the condensate storage tank. These valves are locked open and will have special administrative controls-.

There were no design deficiencies noted by this simplified reliability analysis; therefore, no design changes were required.

F. Recommendations

The NRC March 10, 1980 letter instructed applicants to factor the recommendations of Appendix III to NUREG—0611 into plant design. Those recommendations applicable to Comanche Peak are discussed here.

i. GS-1 Tech. Spec. LCO Train Outage Time Limit

CPNPP will have the time limit recommended in the Westinghouse Standard Technical Specifications.

ii. GS—4 Emergency Procedures Backup Water Supply

CPNPP will have an emergency procedure for operators to switch to the backup water supply. See Section 10.4.9.

iii. GS-6 Flow Path Verification

CPNPP will confirm flow path availability of a train that has been out of service to perform periodic testing or maintenance.

iv. Primary AFW Water Source Low Level Alarm

The CPNPP Condensate Storage Tanks have a useable volume of 28,780 gallons of water at the Lo—Low level alarm. Assuming the largest capacity AFW pump is operating, this alarm will allow the operator at least 20 minutes to anticipate the need to make up water or transfer AFW pump suction to the Service Water System.

v. AFW Pump Endurance Test

CPNPP will perform a pump endurance test as part of the pre-startup testing program.

2. For a discussion of how the Auxiliary Feedwater System meets acceptance criteria see FSAR Subsection 10.4.9.

3. Below are listed the AFW System Flowrate design bases and criteria, by question as listed in Enclosure 2 to the March 10, 1980 NRC letter which originally requested the information.

Question 1

a. Identify the plant transient and accident conditions considered in establishing AFWS flow requirements, including the following events:

1) Loss of Main Feed (LMFW)

2) LMFW w/loss of offsite AC power

3) LMFW w/loss of onsite and offsite AC power

4) Plant cooldown

5) Turbine trip with and without bypass

6) Main steam isolation valve closure

7) Main feed line break

8) Main steam line break

9) Small break LOCA

10) Other transient or accident conditions not listed above.

b. Describe the plant protection acceptance criteria and corresponding technical bases used for each initiating event identified above, The acceptance criteria should address plant limits such as:

1) Maximum RCS pressure (PORV or safety valve actuation)

2) Fuel temperature or damage limits (DNB, PCT, maximum fuel central temperature)

3) RCS cooling rate limit to avoid excessive coolant shrinkage

4) Minimum steam generator level to assure sufficient steam generator heat transfer surface to remove decay heat and/or cool down the primary system.

Response to Question 1.a

The reactor plant conditions which impose safety-related performance requirements on the design of the Auxiliary Feedwater System are as follows for Comanche Peak.

- Loss of Main Feedwater Transients
  - Loss of main feedwater with offsite power available
  - Loss of non-emergency AC power (i.e., loss of main 78 feedwater without offsite power available)
- Secondary System Pipe Ruptures
  - Feedline rupture
  - Steamline rupture
- Loss of all AC Power
- Loss of Coolant Accident (LOCA)
- Cool down

Loss of Main Feedwater Transients

The design loss of main feedwater transients are those caused by:

- Interruptions of the Main Feedwater System flow due to a malfunction in the feedwater or condensate system
- Loss of offsite power with the consequential shutdown of the system pumps, auxiliaries, and controls

The transients are discussed in Sections 15.2.7 and 15.2.6.

The Loss of Non-Emergency AC Power (15.2.6), Loss of Normal Feedwater (15.2.7), and Feedline Rupture (15.2.8) events serve as the basis for the minimum flow required by the Auxiliary Feedwater System for CPNPP. The auxiliary feedwater pumps are sized such that sufficient flow against the steam generator safety valve set pressure (with 3% accumulation) will be provided to remove the stored and residual heat even with the worst single failure in the Auxiliary Feedwater System. The Loss of Non-Emergency AC Power and Loss of Normal Feedwater analyses presented in Chapter 15 demonstrate that the Auxiliary Feedwater System is capable of removing the stored and residual heat, thus preventing the overpressurization of the RCS and loss of water through either the pressurizer relief or safety valves. The Feedline Rupture analyses also demonstrate that the Auxiliary Feedwater System capacity is sufficient to prevent RCS overpressurization and uncovering the reactor core.

Secondary System Pipe Ruptures

The feedwater line rupture accident is discussed in Section 15.2.8.

The main steamline rupture accident is discussed in Section 15.1.5. Auxiliary feedwater is not needed during the early phase of the transient but flow to the faulted loop will contribute to an excessive release of mass and energy to containment. Thus, steamline rupture conditions establish the upper limit on auxiliary feedwater flow delivered to a faulted loop. Eventually, however, the Reactor Coolant System will heat up again and auxiliary feedwater flow will be required to be delivered to the non-faulted loops, but at somewhat lower rates than for the loss of feedwater transients described previously. As discussed in Section 10.4.9., provisions have been made in the design of the Auxiliary Feedwater System to limit, control, or terminate the auxiliary feedwater flow to the faulted loop as necessary in order to prevent containment overpressurization following a steamline break inside containment, and to ensure the minimum flow to the remaining unfaulted loops.

Loss of All AC Power

The loss of all AC power is postulated as resulting from accident conditions wherein not only onsite and offsite AC power is lost but also AC emergency power is lost as an assumed common mode failure.

Battery power for operation of protection circuits is assumed available. The Auxiliary Feedwater System provides both an auxiliary feedwater pump power and control source which are not dependent on AC power and which are capable of maintaining the plant at hot shutdown until AC power is restored.

Loss-of-Coolant Accident LOCA

The loss of coolant accidents discussed in Section 15.6.5 do not impose any flow requirements on the AFWS in addition to those required by the other accidents. The following description of the small LOCA is provided here for the sake of completeness to explain the role of the Auxiliary Feedwater System in this transient,

Small LOCA’s are characterized by relatively slow rates of decrease in reactor coolant system pressure and liquid volume. The principal contribution from the Auxiliary Feedwater System following such small LOCA’s is basically the same as the system function during hot shutdown or following a spurious safety injection signal which trips the reactor. Maintaining a water level inventory in the secondary side of the steam generators provides a heat sink for removing decay heat and establishes the capability for providing a buoyancy head for natural circulation. The Auxiliary Feedwater System may be utilized to assist in a system cooldown and depressurization following a small LOCA while bringing the reactor to a cold shutdown condition.

Cooldown

The cooldown function of the Auxiliary Feedwater System is discussed in Section 10.4.9.

Response to Question 1.b

Table II.E.1.1-2 summarizes the criteria which are the general design bases for each event, discussed in the response to Question 1.a, above. Specific assumptions used in the analyses to verify that the design bases are met are discussed in response to Question 2.

The primary function of the Auxiliary Feedwater System is to provide sufficient heat removal capability following reactor trip and to remove the decay heat generated by the core and prevent systam overpressurization. Other plant protection systems are designed to meet short term or pre-trip fuel failure criteria. The effects of excessive coolant shrinkage are evaluated by the analysis of the rupture of a main steam pipe transient. The maximum flow requirement determined by other bases are incorporated into this analysis, resulting in no additional flow requirements.

Question 2

Describe the analyses and assumptions and corresponding technical justification used with plant condition considered in 1.a above including:

a. Maximum reactor power (including instrument error allowance) the time of the initiating transient or accident.

b. Time delay from initiating event to reactor trip.

c. Plant parameter(s) which initiates AFWS flow and time between initiating eveit End introduction AFWS flow steam generator(s)

d. Minimum steam generator water level when initiating event occurs.

e. Initial steam generator water inventory and depletion rate before and after AFWS flow commences -- identify reactor decay heat rate used.

f. Maximum pressure at which steam is released from steam generator(s) and against which the AFW pump must develop sufficient head.

g. Minimum number of steam generators that must receive AFW flow; e.g., 1 out of 2? 2 out of 4?

h. RC flow condition – continued operation of RC pumps or natural circulation.

i. Maximum AFW inlet temperature.

j. Following a postulated steam or feed line break, time delay assumed to isolate temperature and direct AFW flow to intact steam generator(s). AFW pump flow capacity allowance to accommodate the time delay and maintain minimum steam generator water level. Also identify credit taken for primary system heat removal due to blowdown.

k. Volume and maximum temperature of water in main feed lines between steam generator(s) and AFWS connection to main feed line.

l. Operating condition of steam generator normal blowdown following initiating event.

m. Primary and secondary system water and metal sensible heat used for cooldown and AFW flow sizing.

n. Time at hot standby and time to cooldown RCS to RHR system cut in temperature to size AFW water source inventory,

Response to 2

Analyses have been performed for the limiting transients which define the AFWS performance requirements. These analyses have been provided for review. Specifically, they include:

- Loss of main feedwater
- Loss of non-emergency AC power
- Rupture of a main feedwater pipe
- Rupture of a main steam pipe inside containment

In addition to the above analyses, calculations have been performed specifically for Comanche Peak to determine the plant cooldown flow (storage capacity) requirements. The loss of all AC power is evaluated via a comparison to the transient results of a Blackout, assuming an available auxiliary pump having a diverse (non-AC) power supply. The LOCA analysis, as discussed in the response Question 1.b, incorporates the system flow requirements as defined by other transients, and therefore is not performed for the purpose of specifying AFWS flow requirements. Each of the analyses listed above are explained in further detail in the following sections of this response.

Loss of Main Feedwater/Loss of Non-Emergency AC Power

Analyses of a loss of main feedwater, with and without assuming a loss of power to the reactor coolant pumps, were performed in Sections 15.2.6 and 15.2.7 for the purpose of showing that the peak RCS pressure remains below the criterion for Condition II transients and no water relief occurs through the pressurizer relief or safety valves. Sections 15.2.6 and 15.2.7 summarize the assumptions used in these analyses. The analyses assume that the plant is initially operating at 102% (calorimetric error) of the engineered safety features (ESF) design rating, a conservative assumption in defining decay heat and stored energy in the RCS. The reactor is assumed to be tripped on low-low steam generator water level, allowing for level 78 uncertainty. Sections 15.2.6 and 15.2.7 show that there is considerable margin with respect to filling the pressurizer even with the most limiting single active failure in the Auxiliary Feedwater System.

These analyses contribute in establishing the capacity of the auxiliary feedwater pumps and also establish train association of equipment so that these analyses remain valid assuming the most limiting single failure.

Rupture of Main Feedwater Pipe

The double ended rupture of a main feedwater pipe downstream of the main feedwater line check valve is analyzed in Section 15.2.8 which summarizes the assumptions used in this analysis. Reactor trip is assumed to occur when the faulted steam generator is at the low-low level setpoint (adjusted for errors). This conservative assumption maximizes the stored heat prior to reactor trip and minimizes the ability of the steam generator to remove heat from the RCS following reactor trip due to a conservatively small total steam generator inventory. As in the loss of normal feedwater analysis, the initial power rating was assumed to be 102% of the ESF design rating. Auxiliary feedwater flow of 430 gpm was assumed to be delivered to the two non-faulted steam generators 1 minute after reactor trip. At 30 minutes after reactor trip, it is assumed that the operator has isolated the AFWS from the break and a flow of 265 gpm from the second motor-driven auxiliary feed pump is delivered to the third non-faulted steam generator. The criterion that the reactor core remains covered with water is met.

This analysis contributes in establishing the capacity of the auxiliary feedwater pumps, establishes requirements for layout to preclude indefinite loss of auxiliary feedwater to the postulated break, and establishes train association requirements for equipment so that the AFWS can deliver the minimum flow required in 1 minute assuming the worst single failure.

Rupture of a Main Steam Pipe Inside Containment

Because the steamline break transient is a cooldown, the AFWS is not needed to remove heat in the short term. Furthermore, addition of excessive auxiliary feedwater to the faulted steam generator will affect the peak containment pressure following a steamline break inside containment. This transient is performed at four power levels for several break sizes. Auxiliary feedwater is assumed to initiate at the time of the break, independent of system actuation signals. The maximum flow is used for this analysis. Table II.E.1.1-3 summaries the assumptions used in this analysis. At 10 minutes after the break, it is assumed that the operator has isolated the AFWS from the faulted steam generator which subsequently blows down to ambient pressure. The criteria stated in Table II.E.1.1-2 are met.

This transient establishes the maximum allowable auxiliary feedwater flow rate to a single faulted steam generator assuming all pumps operating, establishes the basis for runout protection, if needed, and establishes layout requirements so that the flow requirements may be met considering the worst single failure.

Plant Cooldown

Maximum and minimum flow requirements from the previously discussed transients meet the flow requirements of plant cooldown. This operation, however, defines the basis for tank size, based on the required cooldown duration, maximum decay heat input and maximum stored heat in the system. As previously discussed in the response to Question 1.a, the auxiliary feedwater system partially cools the system to the point where the RHRS may complete the cooldown, i.e., 350°F in the RCS. Table II.E.1.1-3 shows the assumptions used to determine the cooldown heat capacity of the auxiliary feedwater system.

The cooldown is assumed to commence at the maximum rated power, and maximum trip delays and decay heat source terms are assumed when the reactor is tripped. Primary metal, primary water, secondary system metal and secondary system water are all included in the stored heat to

be removed by the AFWS. See Table II.E.1.1-4 for the items constituting the sensible heat stored in the NSSS.

This operation is analyzed to establish minimum tank size requirements for auxiliary feedwater fluid source which are normally aligned.

Question 3

Verify that the AFW pumps in your plant will supply the necessary flow to the steam generator(s) as determined by items 1 and 2 above considering a single failure, Identify the margin in sizing the pump flow to allow for pump recirculation flow, seal leakage and pump wear.

Response to 3

The Auxiliary Feedwater System (AFWS) is designed, and the equipment specified, considering all criteria established by the NSSS supplier.

Each unit of the CPNPP has two motor driven auxiliary feedwater pumps, and one turbine-driven auxiliary feedwater pump. The turbine driven pump can function without AC power.

FSAR Section 10.4.9 provides the auxiliary feedwater pump capacities.

Pump seals are designed to minimize leakage and expected leakage is considered negligible. The pumps are subjected to periodic inspection, testing and maintenance programs. Performance standards will be set for the pumps. If performance degrades below set limits due to wear, the wear rings in the pump will be replaced. The AFWS is equipped with flow-limiting orifices that will limit the flow to a faulted steam generator from the motor-driven pumps to 700 gpm and from the turbine-driven pump to 600 gpm. The total flow to the faulted steam generator will not be more than 1300 gpm, which is less than the 1380 gpm maximum flow stated in Table II.E.1.1-3. The other steam generators will receive more than the minimum required flow.

AFWS flow rates are provided in Sections 15.1.5, 15.2.6, 15.2.7 and 15.2.8. The flow rates assumed in the accident analyses have considered the most limiting single active failure.

4. See Response to 1.E above.

II.E.1.2 Auxiliary Feedwater System Automatic Initiation And Flow Indication

Action Plan Requirements:

"a. Automatic Initiation of the Auxiliary Feedwater System

Provide automatic initiation of all auxiliary feedwater systems, The initiation signals and circuits shall be designed in such a manner that a single failure will not result in the loss of auxiliary feedwater system function. Testability of the initiating signals and circuits shall be a feature of the design. The initiating signals and circuits shall be powered from the emergency buses. Manual capability to initiate the auxiliary feedwater system from the control room must be retained and must be implemented in such a manner that a single failure in the manual circuits will not result in the loss of system function. The a-c motor driven pumps and valves in the auxiliary feedwater system must be included in the

automatic actuation (simultaneous or sequential) of the loads to the emergency buses. The design of the automatic initiating signals and circuits must be such that their failure will not result in the loss of manual capability to initiate the auxiliary feedwater system from the control room."

NUREG 0578, Pg. 10

"b. Auxiliary Feedwater Flow Indication to Steam Generators

Provide safety-grade indication in the control room of auxiliary feedwater flow for each steam generator. The flow instrument channels shall be powered from the emergency buses, consistent with satisfying the power diversity requirements for auxiliary feedwater systems."

- NUREG 0578, Pg. 11

Also see NUREG 0737.

Response to a.

Auxiliary feedwater system initiation as described herein is safety-related. The CPNPP design complies with the stated positions of NUREG-0578 also as described in the detailed responses below; therefore, no design changes were required as a result of related Action Plan requirements. Components which provide this function are listed in Table 17A-1.

NUREG—O578 Positions 1 to 7

"Consistent with satisfying the requirements of General Design Criterion 20 of Appendix A to 10 CFR 50 with respect to the timely initiation of the auxiliary feedwater system, the following requirements shall be implemented in the short term:"

NUREG—O578 Position 1

"The design shall provide for the automatic initiation of the auxiliary feedwater system."

CPNPP Response

The Auxiliary Feedwater System consists of three separate trains. Two of the trains each consist of one 50 percent capacity electric motor driven auxiliary feedwater pump, valves, piping and controls, The third train consists of a 100% capacity turbine driven auxiliary feedwater pump, valves, piping and controls. See FSAR Fig. 10.4-11. The electric motor driven pumps start automatically on:

1. Two out of four Lo-Lo steam generator level signals from any one of four steam generators

2. Trip of both main feedwater pumps (as sensed by hydraulic pressure switches on the feedwater pumps)

3. Station blackout sequence signal

4. Safety injection signal.

The turbine driven pump starts automatically on:

1. Two out of four Lo-Lo steam generator level signals from any two of four steam

2. Station blackout sequence signal.

The pneumatic flow control valve in each of the auxiliary feedwater lines to the steam generators is a normally open, fail open valve. The motor-operated and manual isolation valves in these lines are maintained open by administrative procedure.

NUREG-0578 Position 2

"The automatic initiation signals and circuits shall be designed so that a single failure will not result in the loss of auxiliary feedwater system function."

CPNPP Response

As shown in our response to NUREG-0578, Position 1 above, the auxiliary feedwater initiation circuitry is part of the Engineered Safety Features (ESF) system, and as such, is installed in accordance with IEEE Standard 279. This Standard is referenced in 10 CFR 50.55a(h).

NUREG-0578 Position 3

"Testability of the initiating signals and circuits shall be a feature of the design."

CPNPP Response

The auxiliary feedwater initiation signals and circuitry are testable. Such testability is included as a requirement of the technical specifications.

NUREG-0578 Position 4

"The initiating signals and circuits shall be powered from the emergency buses,"

CPNPP Response

As shown in our responses to Positions 1 and 2, the initiating signals and circuits are a part of the plant engineered safety features. The requirements for the ESF system dictate that the system shall meet the "single failure criteria." To accomplish this, the initiating signals and circuits are powered from separate emergency buses.

The initiating sensors such as steam generator low-low level are powered from separate and redundant nuclear instrumentation and control panels, each of which is supplied by either on-site emergency generators or station emergency batteries. Each of the two redundant Solid State Protection System (SSPS) trains is supplied by separate power sources.

NUREG-0578 Position 5

“Manual capability to initiate the auxiliary feedwater system from the control room shall be retained and shall be implemented so that a single failure in the manual circuits will not result in the loss of system function.”

CPNPP Response

Manual initiation for each train exists in the control room. No single failure in the manual initiation portion of the circuit can result in the loss of auxiliary feedwater system function.

NUREG-0578 Position 6

“The a-c motor-driven pumps and valves in the auxiliary feedwater system shall be included in the automatic actuation (simultaneous and/or sequential) of the loads to the emergency buses.”

CPNPP Response

As with all ESF equipment, the a-c motor-driven pumps and all valves in the system are automatically transferred to, and sequentially loaded on, the emergency buses on loss of offsite power.

NUREG-0578 Position 7

“The automatic initiating signals and circuits shall be designed so that their failures will not result in the loss of manual capability to initiate the AFWS from the control room.”

CPNPP Response

All automatic and manual initiating signals and circuits are installed in accordance with regulatory requirements and are safety grade and redundant. No single failure in the automatic portion of the system will result in loss of the capability to manually initiate the AFWS from the control room.

NUREG-0578 Position

“In the long term, the automatic initiation signals and circuits shall be upgraded in accordance with safety grade requirements.”

CPNPP Response

As described in the preceding responses, the automatic initiating signals presently meet safety grade requirements. No upgrading is required.

CPNPP Response to b.

Auxiliary feedwater system flow as described herein is safety-related. The CPNPP design complies with the stated positions of NUREG-0578 also as described in the responses below; therefore, no design changes were required as a result of related Action Plan requirements. Components which provide this function are listed in Table 17A-1.

NUREG-0578 Positions 1 and 2

Consistent with satisfying the requirements set forth in General Design Criterion 13 to provide the capability in the Control Room to ascertain the actual performance of the AFWS when it is called to perform its intended function, the following requirements shall be implemented:

NUREG-0578 Position 1

Safety-grade indication of auxiliary feedwater flow to each steam generator shall be provided in the Control Room.

CPNPP Response

Two safety-grade indicators of auxiliary feedwater flow to each steam generator are provided in the Control Room. In addition, safety-grade auxiliary feedwater flow indication is provided for each auxiliary feedwater pump.

These flow indicators are included in the human factors analysis of the Control Room which is discussed under item I.D.1.

NUREG-0578 Position 2

The auxiliary feedwater flow instrument channels shall be powered from the emergency buses consistent with satisfying the emergency power diversity requirements of the auxiliary feedwater system set forth in Auxiliary Systems Branch Technical Position 10-1 of Standard Review Plan, Section 10.4.9.

CPNPP Response

Of the two safety-grade indicators of auxiliary feedwater flow to each steam generator, one is powered from a Train A vital instrument ESF bus and the other from a Train B vital instrument ESF bus.

The pump flow indicators are powered from the vital instrument ESF bus of the same train as the pump. The turbine driven pump flow indication is from Train A.

II.E.3 DECAY HEAT REMOVAL

OBJECTIVE:

“Improve the reliability and capability of nuclear power plant systems for removing decay heat and achieving safe shutdown conditions following transients and under post accident conditions.”

- NUREG 0600, Pg. II.E.3-1

II.E.3.1 Reliability of Power Supplies for Natural Circulation

Action Plan Requirements:

Consistent with satisfying the requirements of General Design Criteria 10, 14, 15, 17, and 20 of Appendix A to 10 CFR Part 50 for the event of loss of offsite power, the following positions shall be implemented:

(1) The pressurizer heater power supply design shall provide the capability to supply, from either the offsite power source or the emergency power source (when offsite power is not available), a predetermined number of pressurizer heaters and associated controls necessary to establish and maintain natural circulation at hot standby conditions. The required heaters and their controls shall be connected to the emergency buses in a manner that will provide redundant power supply capability.

(2) Procedures and training shall be established to make the operator aware of when and how the required pressurizer heaters shall be connected to the emergency buses. If required, the procedures shall identify under what conditions selected emergency loads can be shed from the emergency power source to provide sufficient capacity for the connection of the pressurizer heaters.

(3) The time required to accomplish the connection of the preselected pressurizer heater to the emergency buses shall be consistent with the timely initiation and maintenance of natural circulation conditions.

(4) Pressurizer heater motive and control power interfaces with the emergency buses shall be accomplished through devices that have been qualified in accordance with safety-grade requirements.

- NUREG 0737

CPNPP Response

Power is supplied to four pressurizer heater groups from offsite power, when available, and from the onsite emergency diesel generators through ESF buses. Redundancy is provided by supplying two groups of pressurizer heaters from each redundant ESF train, Control power for manual on/off control of each of these four heater groups is supplied from the 125 volt DC ESF bus in the same train as the main power supply.

Procedures are established to control Reactor Coolant System pressure and temperature. Per Westinghouse analysis, pressurizer heaters are not required during natural circulation cooldown to Hot Shutdown or Cold Shutdown.

No loads need to be shed from the emergency power source to provide sufficient capacity for the connection of the pressurizer heaters.

The electrical interface between each of the four pressurizer heater groups and its associated F bus of concern is through a circuit breaker which trips on an “S” signal and is qualified in accordance with safety-grade requirements. The manual controls for these breakers are qualified in accordance with safety-grade requirements.

II.E.4 CONTAINMENT DESIGN

OBJECTIVE:

“Improve the reliability and capability of nuclear power plant containment structures to reduce the radiological consequences and risks to the public from design basis events and degraded—core and core—melt accidents.”

- NUREG 0660, Pg. II.E.4-1

II.E.4.1 Dedicated Penetration

Action Plan Requirements:

Plants using external recombiners or purge systems for postaccident combustible gas control of the containment atmosphere should provide containment penetration systems for external recombiner or purge systems that are dedicated to that service only, that meet the redundancy and single—failure requirements of General Design Criteria 54 and 56 of Appendix A to 10 CFR 50, and that are sized to satisfy the flow requirements of the recombiner or purge system.

The procedures for the use of combustible gas control systems following an accident that results in a degraded core and release of radioactivity to the containment must be reviewed and revised, if necessary.

- NUREG 0737

CPNPP Response

Post accident combustible gas contol vis external hydrogen purge or internal electric hydrogen recombiners is no longer required as described in Section 6.2.5. See Section 6.2.4 for containment penetration isolation.

II.E.4.2 Isolation Dependability

Action Plan Requirements:

“Provide containment isolation on diverse signals in conformance with Section 6.2.4 of the Standard Review Plan, review isolation provisions for non-essential systems and revise as necessary, and modify containment isolation designs as necessary to eliminate the potential for inadvertent reopening upon reset of the isolation signal.”

- NUREG 0578, Pg. 8

"(1) Containment isolation system designs shall comply with the recommendations of Standard Review Plan Section 6.2.4, (i.e., that there be diversity in the parameters sensed for the initiation of containment isolation).

"(2) All plant personnel shall give careful consideration to the definition of essential and nonessential systems, identify each system determined to be nonessential, describe the

basis for selection of each essential system, modify their containment isolation designs accordingly, and report the results of the reevaluation to the NRC.

"(3) All nonessential systems shall be automatically isolated by the containment isolation signal.

"(4) The design of control systems for automatic containment isolation valves shall be such that resetting the isolation signal will not result in the automatic reopening of containment isolation valves. Reopening of containment isolation valves shall require deliberate operator action.

"(5) The containment setpoint pressure that initiates containment isolation for nonessential penetrations must be reduced to the minimum compatible with normal operating conditions.

"(6) Containment purge valves that do not satisfy the operability criteria set forth in Branch Technical Position CSB 6-4 or the Staff Interim Position of October 23, 1979 must be sealed closed, as defined in SRP 6.2.4, Item II.3.f during operational conditions 1, 2, 3, and 4. Furthermore, these valves must be verified to be closed at least every 31 days." (A copy of the Staff Interim Position is enclosed as Attachment 1.)

"(7) Containment purge and vent isolation valves must close on a high radiation signal.

- NUREG 0737

CPNPP Response

1. There are two phases of containment isolation at CPNPP. Phase A isolates all nonessential process lines but does not effect safety injection, containment spray, component cooling water supplied to the reactor coolant pumps, or auxiliary feedwater. Phase B isolates all process lines except safety injection, containment spray, and auxiliary feedwater.

   Phase A isolation is initiated by high containment pressure, low steam line pressure, low pressurizer pressure, or manual initiation. Phase B isolation is initiated by high-high containment pressure or manual initiation.

   In addition, containment ventilation isolation is initiated by Phase A isolation, containment spray actuation, or high containment radioactivity.

   This system fully complies with Section 11.6 of the SRP 6.2.4. Compliance with all remaining sections of SRP 6.2.4 is documented in Section 6.2.4.

2. A reevaluation of the classification assigned to each process penetration has been performed and is described in revised Section 6.2.4.3.

3. All nonessential systems use either normally closed manual valves or the valves are automatically isolated on a containment isolation signal. See revised Section 6.2.4.3.

4. The CPNPP design complies with the position. The operator must reset each device individually as desired. See revised Section 7.3.1.1.4.

5. The CPNPP containment pressure setpoint (Hi-1) that initiates containment isolation for non-essential penetrations is 3.2 psig. This setpoint is the minimum compatible with normal operating conditions and the value used in accident analyses.

6. The containment isolation valves for the containment purge system are automatic isolation valves. Furthermore, these valves will be closed during operational modes 1, 2, 3 and 4 (see response to Question 022.20). These valves will be verified to be closed at least every 31 days.

7. CPNPP complies as described in Section 6.2.4.

TABLE II.E.1.1-2
CRITERIA FOR AUXILIARY FEEDWATER SYSTEM DESIGN BASIS CONDITIONS

Condition or Transient	Classification[a]	Criteria	Additional Design Criteria
Loss of Main Feedwater	Condition II	Peak RCS pressure not to exceed design pressure +10%. No consequential fuel failures	Pressurizer does not fill.
Loss of Non-Emergency AC Power	Condition II	(Same as LMFW)	Pressurizer does not fill.
Feedline Rupture	Condition IV	10CFR100 dose limits. Containment design pressure not exceeded	Core does not uncover.
Loss of all A/C Power	N/A	Note 1	Same as loss of non-emergency A/C power assuming turbine driven pump
Loss of Coolant	Condition IIII	10 CFR 100 dose limits 10 CFR 50 PCT limits	
	Condition IV	10 CFR 100 dose limits 10 CFR 50 PCT limits	
Main Steamline Break	Condition IV	Containment design pressure and temperature not exceeded	
Cooldown	N/A		100°F/hr 557° to 350°F

a) Ref: ANSI N18.2 (This information provided for those transients performed in the FSAR).

Note:

1 Although this transient establishes the basis for AFW pump powered by a diverse power source, this is not evaluated relative to typical criteria since multiple failures must be assumed to postulate this transient.

TABLE II.E.1.1-3
SUMMARY OF ASSUMPTIONS USED IN AFWS DESIGN VERIFICATION ANALYSES

(Sheet 1 of 2)

Transient		Cooldown	Main Steamline Break (containment)
a.	Max reactor power	3644 MWt	0, 30, 70, 102% of rated (percent of 3425 MWt)
b.	Time delay from event to Rx trip	2 sec	variable
c.	AFWS actuation signal/time delay for AFWS flow	N/A	Assumed immediately @ 0 sec (no delay)
d.	SG water level at time of reactor trip	N/A	N/A
e.	Initial SG inventory	70,760 lbm/SG at 544.6°F	consistent with power
	Rate of change before & after AFSW actuation	N/A	N/A
	Decay heat	N/A	ANS + 20%
f.	AFW pump design pressure	1236 psia	N/A
g.	Minimum # of SGs which must receive AFW flow	N/A	N/A
h.	RC pump status	Tripped	All operating
i.	Maximum AFW temperature	100°F	440°F
j.	Operator action	N/A	10 minutes
k.	MFW purge volume/ S/G temperature	450 ft^3/440°F	800 ft^3/loop (for dryout time)

TABLE II.E.1.1-3
SUMMARY OF ASSUMPTIONS USED IN AFWS DESIGN VERIFICATION ANALYSES

(Sheet 2 of 2)

Transient		Cooldown	Main Steamline Break (containment)
l.	Normal blowdown	none assumed	none assumed
m.	Sensible heat	Table II.E.1.1-4	N/A
n.	Time at standby/time to cooldown to RHR	2 hr/4 hrs	N/A
o.	AFW flow rate	variable	1380 gpm (constant) to faulted SG.

Note:

Refer to Sections 15.2.6, 15.2.7 and 15.2.8 for the assumptions used in the Loss of Non-Emergency AC Power, Loss of Main Feedwater and Feedline Break events.

TABLE II.E.1.1-4
SUMMARY OF SENSIBLE HEAT SOURCES

Primary Water Sources (initially at rated power temperature and inventory)

- RCS fluid
- Pressurizer fluid (liquid and vapor)

Primary Metal Sources (initially at rated power temperature)

- Reactor coolant piping, pumps and reactor vessel
- Pressurizer
- Steam generator tube metal and tube sheet
- Steam generator metal below tube sheet
- Reactor vessel internals

Secondary Water Sources (initially at rated power temperature and inventory)

- Steam generator fluid (liquid and vapor)
- Main feedwater purge fluid between steam generator and AFWS piping.

Secondary Metal Sources (initially at rated power temperature)

- All steam generator metal above tube sheet, excluding tubes.

TABLE II.E.1.1-5
THIS TABLE HAS BEEN DELETED

II.F INSTRUMENTATION AND CONTROLS

OBJECTIVE:

"Provide instrumentation to monitor plant variables and systems during and following an accident. Indications of plant variables and status of systems important to safety are required by the plant operator (licensee) during accident situations to (1) provide information needed to permit the operator to take preplanned manual actions to accomplish safe plant shutdown; (2) determine whether the reactor trip, engineered safety features systems, and manually initiated systems are performing their intended functions (i.e., reactivity control, core cooling, maintaining reactor coolant system integrity, and maintaining containment integrity); (3) provide information to the operator that will enable him to determine the potential for a breach of the barriers to radioactivity release (i.e., fuel cladding, reactor coolant pressure boundary, and containment) and if a barrier has been breached; (4) furnish data for deciding on the need to take unplanned action if an automatic or manually initiated safety system is not functioning properly or the plant is not responding properly to the safety systems in operation; (5) allow for early indication of the need to initiate action necessary to protect the public and for an estimate of the magnitude of the impending threat; and (6) improve requirements and guidance for classifying nuclear power plant instrumentation, control, and electrical equipment important to safety."

-NUREG 0660, pg. II.F-1

II.F.1 ADDITIONAL ACCIDENT MONITORING INSTRUMENTATION.

Action Plan Requirements:

"Item II.F.1 of NUREG-0660 contains the following subparts:

(1) Noble gas effluent radiological monitor:

(2) Provisions for continuous sampling of plant effluents for postaccident releases of radioactive iodines and particulates and onsite laboratory capabilities (this requirement was inadvertently omitted from NUREG-0660; see Attachment 2 that follows, for position);

(3) Containment high-range radiation monitor;

(4) Containment pressure monitor;

(5) Containment water level monitor; and

(6) Containment hydrogen concentration monitor.

"NUREG-0578 provided the basic requirements associated with items (1) through (3) above. Letters issued to all operating nuclear power plants dated September 13, 1979 and October‘ 30, 1979 provided clarification of staff requirements associated with items (1) through (6) above. Attachments 1 through 6 present the NRC position on these matters."

-NUREG-0737

CPNPP Response

The use of the additional accident monitoring instrumentation as listed will be integrated into the operating procedures and training programs prior to fuel load:

(1) Noble Gas Monitor

The CPNPP design will include wide range noble gas monitors for the plant vent stack which will detect and measure concentrations of noble gas fission products in plant gaseous effluents during and following an accident.

An adjacent-to-line monitor will be provided for each main steam line to monitor the concentration in steam that may be released to the environment by the safety or relief valves.

For description of these monitors, see Section 11.5.

(2) Iodine/Particulate Sampling

The wide range noble gas monitor discussed above provides the capability to sample the plant vent stacks as required.

For description, see Section 11.5.

(3) Containment High Range Radiation Monitor

The redundant Category 1 monitors will be located in each Containment Building at Elevation 905'-9". Exact location is provided in Figure II.F-1. To ensure valid data, these monitors will be located at least 90E apart and will not be located adjacent to process piping.

Monitor special calibration and environmental qualification will be performed as specified in Table II.F.1-3 of NUREG-0737.

For further discussion, see Section 12.3.

(4) Containment Pressure

The CPNPP design will include redundant wide range pressure indication (0 - 150 psig) on the Main Control Board meeting Regulatory Guide 1.97 Rev. 2 requirements. In addition this parameter will be provided as input to the SPDS high level display.

The present CPNPP design includes four channels of intermediate range pressure indication (-5 to + 60 psig) on the Main Control Board meeting Regulatory Guide 1.97 Rev. 2 requirements. In addition this parameter will be provided as input to the SPDS high level display.

(5) Containment Water Level

CPNPP design will include redundant wide range containment level indication (elevation 808'-3" to 817' - 6) on the Main Control Board meeting the intent of Regulatory Guide 1.97 Rev. 2 requirements. In addition this parameter will be provided as input to the SPDS high level display. These transmitters measure volume in excess of 600,000 gallons. CPNPP design will also include normal sump level indications (0 - 3 feet) on the Main Control Board. The containment wide range level indication covers the maximum expected flooding levels assuming the reactor cavity is blocked and does not receive any flood water to simulate the most limiting post-accident condition (flooding starts at El. 808'). Actual post-accident conditions would include flooding into the reactor cavity sump (781'-2") and reactor cavity (783'-7"). Therefore, containment narrow range level indication is not considered as required for accident monitoring.

(6) Containment Hydrogen

See Sections 6.2.5.2.3 and 7.5 for containment hydrogen monitoring.

II.F.2 IDENTIFICATION OF AND RECOVERY FROM CONDITIONS LEADING TO INADEQUATE CORE COOLING

Action Plan Requirements:

"Licensees shall provide a description of any additional instrumentation or controls (primary or backup) proposed for the plant to supplement existing instrumentation (including primary coolant saturation monitors) in order to provide an unambiguous, easy-to-interpret indication of inadequate core cooling (ICC). A description of the functional design requirements for the system shall also be included. A description of the procedures to be used with the proposed equipment, the analysis used in developing these procedures, and a schedule for installing the equipment shall be provided."

-NUREG-0737

CPNPP Response

The CPNPP design will include redundant instrumentation to monitor the approach to, existence of and recovery from inadequate core cooling. The monitored parameters will be the reactor coolant system (RCS) saturation margin, the collapsed water level above the reactor core and the RCS temperature at the core exit.

An indication of a declining margin to saturation in the RCS will provide the earliest warning that conditions are developing which could lead to ICC. If the event is allowed to progress, saturation conditions will be observed along with an indication of a declining collapsed water level above the reactor core. Collapsed water level alone does not identify the existence of ICC, only the potential for ICC. Maintaining the collapsed water level at a point above the core is not essential for adequate core cooling. A steam/water froth region extending down into the core could equate to a collapsed water level below the top of the core and yet provide adequate core cooling. Only as the top of the froth region drops below the top of the core would ICC tend to occur. RCS pressure and core exit temperatures would indicate this phase of the event by a "saturation" margin in the superheat region. Alternatively, the recovery from ICC and the subsequent stages

of the event can be monitored to verify that corrective actions taken have resulted in the expected plant response.

The instrumentation to be used for monitoring the RCS saturation margin, collapsed water level, and core exit temperatures is described below.

II.F.2.1 RCS Saturation Margin

The core cooling monitor is a microprocessor-based system capable of determining the saturation margin in the RCS. This determination is based on the lower measurement of the hot leg or pressurizer pressure and the highest measured temperature in the RCS. The temperature used for the most current calculation and the saturation margin are displayed together on the main control board. Redundant microprocessor systems and sensor devices will maintain independence between the two separate trains of temperature and pressure data.

II.F.2.2 Collapsed Water Level

To provide the capability for measurement of the reactor coolant inventory in the upper head and plenum regions of the reactor vessel, CPNPP has decided to install a heated junction thermocouple (HJTC) system supplied by Combustion Engineering, Inc. (C-E). This system includes two identical probes located 180° apart, each in the immediate vicinity of a cold leg inlet. Each probe assembly contains a series of eight HJTC sensors with individual splash shields which are axially distributed inside a separator tube. An HJTC sensor consists of two physically separated thermocouple junctions, one of which is electrically heated. The basic principle of the system is to determine whether or not a sensor is covered with water by detecting the temperature difference between adjacent heated and unheated thermocouples.

The HJTC probe has undergone extensive tests by C-E and has demonstrated its ability to indicate the coolant inventory in the reactor vessel above the core.

When the collapsed water level inside the probe falls below a given sensor location during a loss-of coolant event, the heated junction temperature increases due to the relatively poor cooling ability (lower heat transfer coefficient) of steam instead of water. When the relative temperature difference between heated and unheated junctions exceeds a predetermined value, the sensor registers as being uncovered (i.e., surrounded by steam only). Once a sensor becomes uncovered, the potential increase in temperature of the heated junction depends upon the sensor heater power and the pressure. At low pressures, a high heater power can produce excessive junction temperatures and possible sensor failure. Therefore, a heater power control system is used to preclude excessive temperatures. However, should sensor damage occur due to overheating, the loss of a single HJTC sensor within a probe will not seriously compromise the resolution of usefulness of the HJTC probe measurements due to system redundancy and the independence of the sensors within the probe.

The probes for CPNPP will be of the “split-probe” design, having two sensors located in the upper head region and six sensors located in the upper plenum region. Sudden depressurization of the upper plenum could result in localized voiding with no immediate comparable occurrence in the upper head region due to the limited pressure equalization vent area in the upper support plate. The resulting pressure disequilibrium could result in high ambiguous indications without the “split-probe” design. This design will allow an unambiguous indication of collapsed water level in either region regardless of their instantaneous relative pressure. The measurement of

collapsed water level in either region above the core will give immediate indication to the reactor operator that a loss-of-coolant condition exists and that the approach to ICC is imminent unless proper corrective actions are taken.

The control board display will be in the form of two “mimic” probes, each composed of a column of light emitting diodes (LED’s) corresponding to the eight HJTC sensors in each probe. Sensors which are surrounded by water will be indicated by energizing the corresponding LED.

II.F.2.3 Reactor Coolant System Temperatures

The original, vendor supplied system of core exit thermocouples (CET) and resistance temperature detectors (RTD) will be used to supply the necessary temperature data for the core cooling monitoring system. The saturation margin monitor will be the primary data link for the CET’s. The plant process/ERF computers will have on-line access to the data but are secondary and isolated from this primary link. The core cooling monitor will pass a complete set of input and output data in engineering units to these computers following each calculation cycle. The set of fifty CET’s have been divided into two redundant trains, each representative of all four quadrants of the core. Although originally a non-safety class system, necessary modifications have been made to upgrade all of the system components to Class 1E. Maximum achievable train separation is maintained; however, complete separation is impossible in the reactor head region. Due to retrofit limitations, the two trains share reactor vessel head penetrations where a degree of physical separation is achieved with each individual thermocouple in a separate stainless steel sleeve. Above the vessel head, the messenger wires of the two safety trains are bundled separately and are physically separated from each other and from non-safety Train C cables to the greatest extent possible. Complete train separation is achieved above the CRDM Seismic Support Assembly’s platform (Unit 1) and the missile shield (Unit 2). All connectors and cold junction terminals have been upgraded to Class 1E. Thermocouple leads from the thermocouples to the cold junction terminals are mineral-oxide insulated and stainless steel jacketed.

The average bulk coolant temperature in each hot or cold leg of the primary reactor coolant loop is individually monitored by three RTDs in separate thermowells in each leg near the reactor vessel. These are also divided into two trains with either a hot or cold leg from each of the four loops represented in each train.

Computer software for the core cooling monitor is designed to limit the error introduced by the calculations themselves to less than 0.5°F. Thus, the primary sources of system inaccuracy are sensor inaccuracy first and the initial analog to digital conversion second. Core Cooling Monitor system accuracy is ±3.5°F. User modifiable parameter ranges are incorporated in the software to facilitate automatic testing for out-of-range data. The primary thermocouple temperature limits directly result from these ranges and from the potential loss of physical integrity of Type K thermocouples at elevated temperatures. Instrumentation ranges are listed in Table II.F.2-1.

II.F.2.4 Implementation

CPNPP will establish acceptable operation of the upgraded CETs and the core cooling monitors prior to fuel loading in Unit 1. Necessary modifications to the RCS pressure boundary have been incorporated to allow installation of the HJTC probes. Final installation and implementation of the HJTC probes are complete.

CPNPP Emergency Operating Procedures (EOPs) have incorporated the saturation margin monitor instrumentation and the HJTC instrumentation. The CPNPP EOPs are based on the analyses and generic Emergency Response Guideline Procedures developed by the Westinghouse Owners Group.

TABLE II.F.2-1
SATURATION MARGIN MONITOR AND CORE EXIT THERMOCOUPLE
SPECIFICATION SUMMARY

	PARAMETER	RANGE
INPUT:	Coolant Pressure (1)	0-3000 PSIG
	Pressurizer Pressure (1)	1700-2500 PSIG
	Coolant Temperature (4)	0-700°F
	Type K Thermocouple (25)	0-2300°F
	Cold Junction Temperature (3)	32°-500°F
OUTPUT:	Margin (1)	300°F subcooling to 300°F superheat
	Hottest Thermocouple (1)	0-2300°F
	Data (2)	All inputs and outputs in engineering units each cycle.

Core Cooling Monitor System Accuracy: ± 3.5°F

II.G ELECTRICAL POWER

OBJECTIVE:

"Increase the reliability and diversification of the electrical power supplies for certain safety-related equipment."

-NUREG 0660, pg. II.G-1

II.G.1 POWER SUPPLIES FOR PRESSURIZER RELIEF VALVES AND LEVEL INDICATORS

Action Plan Requirements:

"Consistent with satisfying the requirements of General Design Criteria 10, 14, 15, 17 and 20 of Appendix A to 10 CFR Part 50 for the event of loss-of-offsite power, the following positions shall be implemented:

Power Supply for Pressurizer Relief and Block Valves and Pressurizer Level Indicators

(1) Motive and control components of the power-operated relief valves (PORVs) shall be capable of being supplied from either the offsite power source or the emergency power source when the offsite power is not available.

(2) Motive and control components associated with the PORV block valves shall be capable of being supplied from either the offsite power source or the emergency power source when the offsite power is not available.

(3) Motive and control power connections to the emergency buses for the PORVs and their associated block valves shall be through devices that have been qualified in accordance with safety-grade requirements.

(4) The pressurizer level indication instrument channels shall be powered from the vital instrument buses. The buses shall have the capability of being supplied from either the offsite power source or the emergency power source when offsite power is not available."

-NUREG 0737

CPNPP Response

The Pressurizer PORVs are pneumatically operated valves with pilot solenoids.

The pilot solenoids are powered from 125 volt DC emergency buses which can be powered from batteries, offsite power or emergency onsite power.

The Pressurizer PORV controls are powered from the inverter buses which are capable of being fed from offsite and onsite emergency ac power, and the onsite dc power system.

The Pressurizer PORV block valves for CPNPP are motor operated valves. The power for the motors is supplied from class 1E 480 volt buses which may be supplied from either offsite power or onsite emergency diesel generators. Control power is provided from the same buses.

The Pressurizer PORV dc power and control power and the PORV block valve motor power and control power are connected to different emergency ESF buses through devices that are qualified in accordance with safety-grade requirements.

The Pressurizer level indicated circuits are safety-grade and post-accident qualified. AC power for these Class 1E instrument channels is supplied from inverters which are supplied from ESF buses with automatic backup from the emergency batteries.

The power supplies for the PORVs and block valves are listed appropriately in Table 17A-1.

II.K MEASURES TO MITIGATE SMALL-BREAK LOSS-OF-COOLANT ACCIDENT AND LOSS-OF-FEEDWATER ACCIDENTS

OBJECTIVE:

"To perform systems reliability analyses and to effect changes in emergency operating procedures and operator training to improve the capability of plants to mitigate the consequences of the small-break loss-of-coolant accidents (LOCA) and loss-of-feedwater events."

- NUREG 0660, Pg. II.K-1

II.K.1 IE BULLETINS

Action Plan Requirements:

"C.1.5* Review all valve positions, positioning requirements, positive controls and related test and maintenance procedures to assure proper ESF functioning. (See Bulletin 79-06A Item 8, 79-06B Item 7, 79-08 Item 6.)"

"C.1.10 Review and modify, as required, procedures for removing safety-related systems for service (and restoring to service) to assure operability status is known. (See Bulletin 79-05A Item 10, 79-06A Item 10, 79-06B Item 9, 79-08 Item 8.)"

"C.1.17 For Westinghouse-designed reactors, trip the pressurizer low-level coincident signal bistables, so that safety injection would be initiated when the pressurizer low-pressure setpoint is reached regardless of the pressurizer level. (See Bulletin 79-06A and Revision 1, Item 3.)"

-NUREG 0694, pg. 17

CPNPP Response

II.K.1 Procedures will be reviewed and, as necessary, revised to address the removal of safety-related systems from service (and restoring to service) to assure proper operability.

II.K.1.5 CPNPP will review all safety-related valve positions, positioning requirements, and positive controls to assure that valves remain positioned (open or closed) in a manner to ensure the proper operation of engineered safety features.

CPNPP will review and modify as necessary those related maintenance, testing, startup, and supervisory periodic surveillance procedures to ensure that safety-related valves are returned to their correct positions following manipulations and are so maintained during all operational modes.

II.K.1.10 CPNPP will review and modify as necessary the maintenance and test procedures to ensure that they require:

(a) Verification, by test or inspection, of the operability of redundant safety-related systems prior to the removal of any safety-related system from service.

(b) Verification of the operability of all safety-related systems when they are returned to service following maintenance or testing.

(c) Explicit notification of involved reactor operations personnel whenever a safety-related system is removed from and returned to service.

II.K.1.17 FSAR Section 15.6 discusses CPNPP protection from decrease in reactor coolant inventory. Pressurizer low level trips are not utilized at CPNPP.

II.K.2.13 Thermal Mechanical Report – Effect of High-Pressure Injection on Vessel Integrity for Small-Break Loss-of-Coolant Accident With No Auxiliary Feedwater

Action Plan Requirements:

"A detailed analysis shall be performed of the thermal-mechanical conditions in the reactor vessel during recovery from small breaks with an extended loss of all feedwater."

Changes to Previous Requirements and Guidance

"Also, this requirement has been changed to include all operating pressurized-water reactors (PWRs) and applicants."

- NUREG 0737

CPNPP Response

II.K.2.13 To address the requirements of detailed analysis of the thermal-mechanical conditions in the reactor vessel during recovery from small-break LOCAs with loss of all feedwater, the Westinghouse Owner's Group (WOG) has initiated a number of programs applicable to generic Westinghouse plants. Results of these programs are summarized in the following reports.

(1) "Summary Report on Reactor Vessel Integrity for Westinghouse Operating Plants," WCAP-10019, December 1981 (transmitted via Ref. #1).

(2) "Summary of Evaluations Related to Reactor Vessel Integrity performed for the Westinghouse Owner's Group," May 1982 (transmitted via Ref. 2).

Although these reports are primarily directed to demonstrating that there are no near-term safety concerns for operating Westinghouse plants, the

analytical methodologies and general conclusions are applicable to CPNPP.

Pressurized thermal shock is not expected to be a problem at CPNPP because of reactor vessel material properties. Based on the conservative material assumptions described in the Technical Specifications, the limiting material RT_{ndt} changes from an initial value of 40°F to 110°F (1/4 T) after 16 EFPY of fast neutron fluence is well below the proposed NRC screening criterion of 270°F (Ref. 3).

The limiting RT_{ndt} will be benchmarked and updated during CPNPP operation using neutron fluence data provided by the in-situ capsule surveillance program. This updating will include the reevaluation of the prediction of RT_{ndt}. If an extrapolated RT_{ndt} value were to violate the NRC screening criteria, then CPNPP would respond with an appropriate action plan according to NRC requirements.

2. Letter OG-70, dated May 28, 1982, O. D. Kingsley (WOG) to H. R. Denton (NRC).

3. “NRC Evaluation of Pressurized Thermal Shock” (draft), U.S. NRC, September 13, 1982.

II.K.2.17 Potential for Voiding in the Reactor Coolant System During Transients

Action Plan Requirements:

“Analyze the potential for voiding the reactor coolant system (RCS) during anticipated transients.”

Changes to Previous Requirements and Guidance

“The previous requirement has been to include all PWR operating reactors and applicants.”

- NUREG 0737

CPNPP Response

II.K.2.17 Westinghouse (in support of the Westinghouse Owner’s Group) has performed a study which addresses the potential for void formation in Westinghouse designed Nuclear Steam Supply Systems during natural circulation cooldown/ depressurization transients. The study has been submitted to the NRC by the Westinghouse Owners Group (Letter OG-57, dated April 20, 1981, R. W. Jurgensen to P. S. Check) and is applicable to Comanche Peak Nuclear Power Plant.

In addition, the Westinghouse Owners Group has developed a natural circulation cooldown guideline that takes the results of the study into account so as to preclude void formation in the upper head region during natural circulation cooldown/depressurization transients, and specifies those conditions under which upper head voiding may occur. These Westinghouse Owners Group generic guidelines have been submitted to the NRC (Letter OG-64, dated November 30, 1981, R. W. Jurgensen to D. G. Eisenhut). The generic guidance developed by the Westinghouse Owners Group (augmented as appropriate with plant specific consideration) will be utilized in the implementation of the CPNPP Emergency Operating Procedures.

II.K.2.19 Sequential Auxiliary Feedwater Flow Analysis

Action Plan Requirements:

"Provide a benchmark analysis of sequential auxiliary feedwater (AFW) flow to the steam generators following a loss of main feedwater."

Changes to Previous Requirements and Guidance

"The previous requirement has been changed to include all operating pressurized-water reactors (PWRs) and applicants for operating license."

- NUREG 0737

CPNPP Response

II.K.2.19 This requirement is not applicable to plants with inverted U-tube steam generators such as the Westinghouse steam generators for Comanche Peak.

II.K.3 FINAL RECOMMENDATIONS FOR B&O TASK FORCE

II.K.3.1 Installation and Testing of Automatic Power-Operated Relief Valve Isolation System

Action Plan Requirements:

"All PWR licensees should provide a system which uses the PORV block valve to protect against a small-break loss-of-coolant accident. This system will automatically cause the block valve to close when the reactor coolant system pressure decays after the PORV has opened. Justification should be provided to assure that failure of this system would not decrease overall safety by aggravating plant transients and accidents."

"Each licensee should perform a confirmatory test of the automatic block valve closure system following installation."

- NUREG 0737

CPNPP Response

I.K.3.1 Based on the reduction in PORV LOCA frequency due to post-TMI modifications already implemented, and automatic PORV block valve closure system is unnecessary and therefore not incorporated. See the response to II.K.3.2 below and WCAP-9804 for further discussion.

II.K.3.2 Report on Overall Safety Effect of Power-Operated Relief Valve Isolation System

Action Plan Requirements:

"(1) The licensee should submit a report for staff review documenting the various actions taken to decrease the probability of a small-break loss-of-coolant accident (LOCA) caused by a stuck- open power-operated relief valve (PORV) and show how these actions constitute sufficient improvements in reactor safety."

"(2) Safety-valve failure rates based on past history of the operating plants designed by the specific nuclear steam supply system (NSSS) vendor should be included in the report submitted in response to (1) above."

- NUREG 0737

CPNPP Response

II.K.3.2 The Westinghouse Owners Group submitted WCAP-9804, "Probabilistic Analysis and Operational Data in Response to Item II.K.3.2 for Westinghouse NSSS Plants" to the NRC on March 13, 1981. This report describes various modifications to Westinghouse plants since TMI and, using probabilistic analysis via event trees, estimates the effect of the post-TMI changes, the modifications described in WCAP-9804 have been incorporated by CPNPP. Therefore, the improvements in reactor safety demonstrated by the WCAP are applicable.

II.K.3.3 Reporting of SV & RV Failures & Challenges

Action Plan Requirements:

"Assure that any failure of a PORV or safety valve to close will be reported to the NRC promptly. All challenges to the PORVs or safety valves should be documented in the annual report."

- NUREG 0694, Pg. 24

CPNPP Response

II.K.3.3 Reporting of SV and RV Failures and Challenges

The CPNPP Emergency Plan requires prompt notification to the NRC of the failure of a SV or RV to close. The reporting of SV & RV challenges was moved from the annual report to the monthly operating report (TS 6.9.1.5), then License Amendment 64 deleted this reporting requirement altogether.

II.K.3.5 Automatic Trip of Reactor Coolant Pumps During Loss-Of-Coolant Accident

Action Plan Requirements:

"Tripping of the reactor coolant pumps in case of a loss-of-coolant accident (LOCA) is not an ideal solution. Licensees should consider other solutions to the small-break LOCA problem (for example, an increase in safety injection flow rate). In the meantime, until a better solution is found, the reactor coolant pumps should be tripped automatically in case of a small-break LOCA. The signals designated to initiate the pump trip are discussed in NUREG-0623."

- NUREG 0737

CPNPP Response

II.K.3.5 TMI Action Plan Item II.K.3.5 has been evaluated in accordance with the guidelines set forth in NRC Generic Letter 83-10c. The Westinghouse Owner's Group (WOG) has performed a series of analyses to determine (1) what unique indicators exist that would distinguish between a SBLOCA and a SGTR, and (2) the 10 CFR 50, Appendix K and Best Estimate predictions of the Peak Cladding Temperatures (PCT) associated with the delayed Reactor Coolant Pump (RCP) trip scenario.

Reference 1 provided the basis for calculating the three (3) unique distinguishing identifiers that exist for CPNPP. The generic WOG Emergency Response Guidelines were then used to develop the plant specific Emergency Operating Procedure (EOP) for the scenario. The CPNPP EOPs will require a manual trip of the RCPs when conditions warrant the action. Reference 2 documents that even for the most limiting Westinghouse plant, the PCTs are below the limits established in NRC Generic Letter 83-10c. This result provides the justification for allowing a manual trip of the RCPs.

References:

(1) OG-110, dated 1 December 1983, J. J. Sheppard (WOG) to R. J. Mattson (NRC).

(2) OG-117, dated 12 March 1984, J. J. Sheppard (WOG) to R. J. Mattson (NRC).

II.K.3.9 Proportional Integral Derivative Controller Modification

Action Plan Requirements:

"The Westinghouse-recommended modification to the proportional integral derivative (PID) controller should be implemented by affected licensees."

- NUREG 0737

CPNPP Response

II.K.3.9 CPNPP has reconfigured the pressurizer power operated relief valve (PORV) controller for proportional-integral (PI) control action. Without derivative action the contribution to the error signal from reactor coolant pressure rate of change has been eliminated. This results in fewer challenges to the reactor protection system from spurious pressure signal noise.

II.K.3.10 Proposed Anticipatory Trip Modification

Action Plan Requirements:

"The anticipatory trip modification proposed by some licensees to confine the range of use to high-power levels should not be made until it has been shown on a plant-by-plant basis that the probability of a small-break loss-of-coolant accident (LOCA) resulting from a stuck- open power-operated relief valve (PORV) is substantially unaffected by the modification."

- NUREG 0737

CPNPP Response

II.K.3.10 The CPNPP design includes the P-9 interlock which blocks the direct reactor trip on a turbine trip at or below 50% of rated thermal power. Analyses have been performed which demonstrate that a turbine trip without direct reactor trip at or below 50% of rated thermal power does not pose any undue or additional challenges to the pressurizer PORVs. Assuming all control systems are operable, neither the RCS PORVs nor the steam generator ARVs reached their respective pressure setpoints. Even when single credible failures in the control systems are considered, the pressurizer PORVs do not reach their setpoints. Also see FSAR Section 7.2.

II.K.3.11 Justification of Use of Certain PORVs

Action Plan Requirements:

"Demonstrate that the PORV installed in the plant has a failure rate that is not significantly less than the valves for which there is an operating history."

- NUREG 0694, Pg. 18

CPNPP Response

II.K.3.11 The CPNPP Pressurizer Power Operated Relief Valves are Copes Vulcan Model No. D-100-160 globe valves. The report on failure rates required by II.K.3.2 will establish the operating history for these valves.

II.K.3.12 Confirm Existence of Anticipatory Reactor Trip Upon Turbine Trip

Action Plan Requirements:

"Licensees with Westinghouse-designed operating plants should confirm that their plants have an anticipatory reactor trip upon turbine trip. The licensee of any plant where this trip is not present should provide a conceptual design and evaluation for one installation of this trip."

- NUREG 0737

CPNPP Response

II.K.3.12 CPNPP has the anticipatory reactor trip on turbine trip as described in Section 7.2.1.1.2, item 6.

II.K.3.17 Report on Outages of Emergency Core-Cooling Systems Licensee Report and Proposed Technical Specification Changes

Action Plan Requirements:

"Several components of the emergency core-cooling (ECC) systems are permitted by technical specifications to have substantial outage times (e.g., 72 hours for one diesel-generator; 14 days for the HPCI system). In addition, there are no cumulative outage time limitations for ECC systems. Licensees should submit a report detailing outage dates and lengths of outages for all ECC systems for the last 5 years of operation. The report should also include the causes of the outages (i.e., controller failure, spurious isolation)."

Changes to Previous Requirements and Guidance

"This clarification adds the requirement to propose changes that will improve and control availability."

- NUREG 0737

CPNPP Response

II.K.3.17 ECCS Outages

The NRC has closed this item for CPNPP. The requirements of 10 CFR 50.72 and 50.73 and reporting on the NPRDS is adequate for reporting ECCS outages.

II.K.3.25 Effect of Loss of Alternating-Current Power on Pump Seals

Action Plan Requirements:

"The licensees should determine, on a plant-specific basis, by analysis or experiment, the consequences of a loss of cooling water to the reactor recirculation pump seal coolers. The

pump seals should be designed to withstand a complete loss of alternating-current (ac) power for at least 2 hours. Adequacy of the seal design should be demonstrated."

Changes to Previous Requirements and Guidance

"The evaluation and proposed modifications shall be submitted by July 1, 1981. The May 7, 1980 letter called for modifications by January 1, 1982. This clarification adds a documentation requirement for the evaluation to the submitted by July 1, 1981. The modification date remains unchanged. Additionally, this task has changed to include Westinghouse and Combustion Engineering operating reactors and operating reactor applicants."

- NUREG 0737

CPNPP Response

II.K.3.25 Loss of cooling water to the reactor coolant pump seal coolers due to loss of offsite power is not applicable to CPNPP because the Component Cooling Water supply to the Non-safeguards loop of the CCWS is through motor operated butterfly valves (1-HV-4526 and 4527 at location E-3 and 1-HV-4524 and 4525 at location D-3 on FSAR Figure 9.2-3) which fail-as-is on loss of power. As discussed in Section 5.4.1.3.1 the effect of loss of offsite power is to cause a temporary stoppage of the cooling water. Power is restored to the component cooling water pumps after 30 seconds (see Table 8.3-2). Therefore, cooling of the seal water heat exchanger and the reactor coolant pump packages described in FSAR Section 9.2.2.2 is restored in a timely manner on a loss of offsite power. The components described are covered under the appropriate items in Table 17A-1.

II.K.3.30 Revised Small-Break Loss-of-Coolant-Accident Methods to Show Compliance With 10 CFR Part 50, Appendix K

Action Plan Requirements:

"The analysis methods used by nuclear steam supply system (NSSS) vendors and/or fuel suppliers for small-break loss-of-coolant accident (LOCA) analysis for compliance with Appendix K to 10 CFR Part 50 should be revised, documented, and submitted for NRC approval. The revisions should account for comparisons with experimental data, including data from the LOFT Test and Semiscale Test facilities."

Changes to Previous Requirements and Guidance

"The changed requirement (1) allows for justification of acceptability of present small-break LOCA models by comparison with test date, and (2) requests each licensee to outline scope and schedule for model revision or comparison with test data by late fall, 1980. The original requirement did not allow provision for showing acceptability of present models by comparison with plant data."

- NUREG 0737

CPNPP Response

II.K.3.30 TUGCO has participated, as a member of the Westinghouse Owners Group in the development of the modified SBLOCA code NOTRUMP. A technical description of the code was submitted to the NRC via References 1 and 2. A favorable SER was released on May 21, 1985, Reference 3.

(3) Safety Evaluation. TMI Action Item II.K.3.30 for Westinghouse Plants attached to NRC letter V. S. Noonan to M. D. Spence dated June 6, 1985.

II.K.3.31 Plant-Specific Calculations to Show Compliance with 10 CFR Part 50.46

Action Plan Requirements:

"Plant-specific calculations using NRC-approved models for small-break loss-of-coolant accidents (LOCAs) as described in item II.K.3.30 to show compliance with 10 CFR 50.46 should be submitted for NRC approval by all licensees."

- NUREG 0737

CPNPP Response

II.K.3.31 In Reference 1, the NRC Staff indicated that the resolution of TMI Action Plan Item II.K.3.31 may be accomplished by generic analyses to demonstrate that the previous NRC approved WFLASH SBLOCA results were conservative when compared with the new NOTRUMP SBLOCA. Such generic studies were undertaken by the Westinghouse Owners Group (WOG) of which Texas Utilities is a participating member. The WOG completed these generic studies and has submitted the results of the analyses to the NRC in the topical report WCAP-11145 (Reference 2). Topical report WCAP-11145 is therefore referenced in order to demonstrate that the requirements to TMI Action Plan II.K.3.31 are satisfied for CPNPP in a generic fashion in accordance with Reference 1.

Topical report WCAP-11145 documents the results of a series of Small Break LOCA (SBLOCA) analyses performed with the NRC approved NOTRUMP SBLOCA Evaluation Model. Cold leg break spectrum analyses were performed for the limiting SBLOCA plant form each of the Westinghouse 4- loop, 4-loop Upper Head Injection (UHI), 3-loop, and 2- loop plant categories. The limiting SBLOCA plant in each category was defined on the basis of previous SBLOCA analyses which were performed with the WFLASH SBLOCA code. In addition to

the cold leg break spectrums, a hot leg and pump suction break were performed as part of the 4- loop plant analyses, confirming that the cold leg was still the worst break location. Comparison of the NOTRUMP cold leg break spectrum results with the previously generated WFLASH results, showed that the WFLASH results were conservative for all plant categories. In particular, for the previous bounding 4-loop peak clad temperature (PCT) plant the NOTRUMP SBLOCA code calculated a PCT which was 537 °F lower than the WFLASH code calculated value. This result is consistent with the other generic studies which indicated that the NOTRUMP SBLOCA calculated PCTs tended to be significantly lower than the previously bounding WFLASH PCTs.

The generic results documented in WCAP-11145, demonstrate that a plant specific reanalysis of CPNPP with the NOTRUMP SBLOCA should result in the calculation of a limiting PCT which would be significantly lower than the 1788°F PCT currently calculated with the WFLASH. Hence, the WFLASH results which currently form the licensing basis for CPNPP are conservative and still valid for demonstrating the adequacy of the Emergency Core Cooling System to mitigate the consequences of a SBLOCA, as required by 10CFR50.46. It is therefore concluded that a plant specific analysis is not needed in order for CPNPP to comply with TMI Action Item II.K.3.31. Rather, Texas Utilities references WCAP-11145 in order to comply with TMI Action Item II.K.3.31 on a generic basis in accordance with Reference 1.

III EMERGENCY PREPAREDNESS AND RADIATION EFFECTS

III.A EMERGENCY PREPAREDNESS AND RADIATION EFFECTS

III.A.1 IMPROVE LICENSEE EMERGENCY PREPAREDNESS - SHORT TERM

OBJECTIVE:

"Promptly improve and upgrade licensee emergency preparedness by requiring improvements in facilities, plans, procedures, offsite support, technical assistance, equipment and supplies required to adequately respond to and manage an accident."

- NUREG 0660, Pg. III.A.1-1

III.A.1.1 Upgrade Emergency Preparedness

Action Plan Requirements:

"Licensees will upgrade emergency preparedness in accordance with the requirements described in the NRC "Action Plan for Promptly Improving Emergency Preparedness" (SECY 79-450), which was distributed to all licensees during regional meetings in August 1979, and in accordance with subsequently issued acceptance criteria (NUREG-0654). These actions include:

(1) Preparing and submitting upgraded plans which satisfy the NRR supplemental acceptance criteria provided by the NRC emergency preparedness review teams, with special attention to the establishment of emergency action levels in accordance with NUREG-0610, "Basis for Emergency Action Levels for Nuclear Power Facilities."

(2) Implementing the short-term emergency planning recommendations of NUREG-0578.

(3) Establishing an onsite Technical Support Center, an onsite Operational Support Center, and a near-site Emergency Operations Facility.

(4) Establishing improved offsite radiological monitoring capability in accordance with the NRR/RAB technical position.

(5) Providing planning assistance to appropriate Federal, State, and Local governments to assure that their emergency response roles are properly coordinated with the facility plan and that such plans satisfy the NRC acceptance criteria.

(6) Providing resources as necessary to State and Local governments for implementing the emergency planning zone concept, in accordance with NUREG-0396, "Planning Basis for the Development of State and Local Government Radiological Emergency Response Plans in Support of Light Water Nuclear Power Plants."

(7) Participating in periodic joint exercises involving Federal, State, and Local government emergency response organizations.

- NUREG 0660, Pg. III.A.1-9

"Provide an emergency response plan in substantial compliance with NUREG-0654, "Criteria for Preparedness and Evaluation of Radiological Emergency Response Plans and Preparedness in Support of Nuclear Power Plants" (which may be modified after May 13, 1980 based on public comments except that only a description of and completion schedule for the means for providing prompt notification to the population (App. 3), the staffing for emergencies in addition to that already required (Table B.1), and an upgraded meteorological program (App. 2) need be provided. NRC will give substantial weight to FEMA findings on offsite plans in judging the adequacy against NUREG-0654. Perform an emergency response exercise to test the integrated capability and a major portion of the basic elements existing within emergency preparedness plans and organizations."

- NUREG 0694, Pg. 25

CPNPP Response

1) The CPNPP Emergency Plan has been written in accordance with the draft version of NUREG-0654 and was submitted to the NRC in October 1980 for review.

2) For implementation of NUREG-0578, 2.1.8.a, Post Accident Sampling, see FSAR Section II.B.3.

   For implementation of NUREG-0578, 2.1.8.b, Accident Monitoring Instrumentation, see FSAR Section II.F.1.

   For implementation of NUREG-0578, 2.1.8.c, Improved Inplant Iodine Instrumentation, see FSAR Section III.D.3.3.

3) See FSAR Section III.A.1.2 and CPNPP Emergency Plan, Section 6.0.

4) See CPNPP Emergency Plan, Section 7.0.

5) Planning assistance is provided to State and Federal agencies upon request. Local planning assistance is provided by Vistra OpCo.

6) Resources to implement the State and Local emergency plans will be made available to those agencies.

7) The State and Local emergency plans provide for periodic joint exercises with CPNPP.

III.A.1.2 Upgrade Licensee Emergency Support Facilities

Action Plan Requirements:

"A separate technical support center shall be provided for use by plant management, technical, and engineering support personnel. In an emergency, this center shall be used for assessment of plant status and potential offsite impact in support of the control room command and control function. The center should also be used in conjunction with implementation of onsite and offsite emergency plans, including communications with an offsite emergency response center. Provide at the onsite technical support center the as-built drawings of general plant arrangements and

piping, instrumentation, and electrical systems. Photographs of as-built system layouts and locations may be an acceptable method of satisfying some of these needs."

"Each operating nuclear power plant should establish and maintain a separate onsite operational support center outside the control room. In the event of an emergency, shift support personnel (e.g., auxiliary operators and technicians) other than those required and allowed in the control room shall report to this center for further orders and assignment."

- NUREG 0578, Pg. 13

Also see NRC Letter, dated April 25, 1980; August 1, 1980; and September 5, 1980.

CPNPP Response

I. INTRODUCTION

CPNPP established emergency response facilities (ERFs), consisting of a Technical Support Center (TSC), an Operational Support Center (OSC), and an Emergency Operations Facility (EOF), prior to issuance of an operating license. These facilities meet the guidelines of NUREG 0578, 0654, 0694, and also meet the intent of NUREG 0696 "Functional Criteria for Emergency Response Facilities," as stated in the description below.

The ERFs have been upgraded by incorporation of an integrated data acquistion and display system. This system provides data to the TSC and EOF and also provides the Safety Parameter Display System (SPDS) displays to the Control Room, TSC and EOF. A description of this system is provided in the discussion below.

The CPNPP Emergency Plan has been revised to describe the existence and function of the current CPNPP emergency response facilities; therefore, facility description in Sections IV, V and VI below for the TSC, OSC and EOF, respectively, are not described in FSAR Section III.A.1.2 but are relocated to the CPNPP Emergency Plan.

II. EMERGENCY RESPONSE FACILITY INSTRUMENTATION, DATA SYSTEM EQUIPMENT, AND POWER SUPPLIES

The data display equipment provided in the TSC and EOF is part of the integrated Emergency Response Facility (ERF) Computer System. As shown in Figure III.A.1.2-2, the integrated ERF Computer System gathers, stores and displays data needed in the TSC and EOF to analyze the plant conditions. The system performs its function independent of action in the Control Room and without degradation or interfering with Control Room and plant functions. Two of four TSC displays are powered by a Non-1E battery backed, Uninterruptable Power Supply (UPS) System; two TSC displays are powered from a Non-Class 1E 120 VAC common supply; EOF displays are powered from an AC source (the 25 KV Plant Support Power Loop).

Signals to the integrated ERF Computer System, which are received from sources providing signals to safety-related equipment or displays, are isolated to ensure that the system will not degrade performance of the safety-related equipment or displays.

Power supplied to the ERF computer will be provided from a Non-1E Battery UPS System to insure the continuity of TSC functions if temporary loss of primary TSC Power sources occurs. Upon loss of all A/C power or a seismic event, the ERF computer will not be functional; however, plant process data can be acquired from other sources.

The design goal for the data system reliability is to achieve an operational unavailability goal of 0.01 during all plant operating conditions above cold shutdown.

The SPDS display equipment used in the TSC and EOF is not seismically qualified; it will have the same design goal of meeting the TSC and EOF data system reliability and performance criteria. The design of the TSC and EOF data system equipment incorporates human factors engineering with consideration for both operating and maintenance personnel. The TSC and EOF display equipment discribed herein is included under the appropriate items in Table 17A-1.

III. TECHNICAL DATA AND DATA SYSTEM

The ERF Computer System receives, stores, processes, and displays information acquired from different areas of the plant as needed to perform the TSC and EOF function. The ERF Computer System provides access to accurate and reliable information sufficient to determine:

1. Plant steady-state operating conditions prior to an accident.

2. Transient conditions producing the initiating event.

3. Plant systems dynamic behavior throughout the course of an accident.

The data set available to the data system is complete enough to permit accurate assessment of an accident without interference with the Control Room emergency operation.

The data set available to the ERF Computer System includes Category 1 and applicable Category 2 Type A, B, C and E Accident Monitoring variables (as described in FSAR Section 7.5) and Type D Accident Monitoring variables which are also identified as Type D variables in Regulatory Guide 1.97, Rev. 2, Table 2.

All sensor data and calculated variables used in the data set for SPDS, EOF, or for transmission to offsite locations are available for display. The accuracy of the data displayed is substantially the same as the accuracy of comparable data displayed in the Control Room. The time resolution of data acquisition is sufficient to provide data without loss of information during transient conditions where that data is necessary for operator action. The time resolution of each sensor signal will respond on the potential transient behavior of the variable being measured.

The ERFCS contains a long-term archival system with disk storage for the TSC and EOF data set. At least one fuel cycle of data is stored by the ERFCS. The sample frequency is consistent with use of the data. Archival data storage is provided automatically and retrieval of historical data is incorporated in the standard HMI display package located on every TSC and EOF workstation and does not impact ERFCS data acquisition function.

A sufficient number of display and printout devices is provided in the TSC and EOF to allow designated personnel to perform their assigned tasks. The displays include alphanumeric and graphical representations of:

1. Plant system variables

2. In-plant radiological variables

3. Meteorological information

Trend information and time history display capability are available to personnel in the TSC and EOF. The displays are designed so that call up, manipulation, and presentation of data can easily be performed. The data display presents information in easily understood formats.

The SPDS can also be displayed in the TSC and EOF.

IV. TECHNICAL SUPPORT CENTER (TSC)

See the CPNPP Emergency Plan, Section 6 and specifically 6.2.

V. OPERATIONAL SUPPORT CENTER (OSC)

See the CPNPP Emergency Plan, Section 6 and specifically 6.3.

VI. EMERGENCY OPERATIONS FACILITY (EOF)

See the CPNPP Emergency Plan, Section 6 and specifically 6.4.

VII. SAFETY PARAMETER DISPLAY SYSTEM (SPDS)

A. FUNCTION

The purpose of the Safety Parameters Display System (SPDS) is to assist control room personnel in evaluating the safety status of the plant. The SPDS provides a continuous high level graphical display of plant parameters or derived variables representative of the safety status of the plant.

As an operator aid, SPDS serves to concentrate a minimum set of plant parameters from which the plant safety status can be assessed. More detailed plant information will be provided by several secondary displays.

Human factor engineering is incorporated in the SPDS design to enhance the functional effectiveness of the control room personnel.

The SPDS will be operational during normal, as well as, emergency conditions except for loss of all A/C power or seismic events. However, data acquisition will remain available from other sources. The SPDS will be able to display pertinent information concerning steady-state and transient conditions.

All portions of the SPDS have been designed and specified such that all design basis safety questions have been considered.

Revision 3 to the SPDS Safety Analysis Report contains further supporting information and analysis, and was transmitted via Reference [1].

B. LOCATION

SPDS displays are available in the Control Room, TSC, and EOF. The SPDS location in the control room will be visible to both the control room operator and the Senior Reactor Operator.

C. SIZE

The SPDS will be compatible with the existing space in the control room area and will not interfere with normal movement or with full visual access to other control room operating systems or displays.

D. STAFFING

The SPDS will be of such design that no operating personnel, in addition to the normal control room operating staff, are required for its operation.

E. DISPLAY CONSIDERATIONS

Vistra OpCo was a member of the Safety Assessment System committee to develop and implement the necessary displays to meet the requirements for the SPDS. The committee consisted of Quadrex Corporation and eleven other utilities owning Westinghouse PWRs. The Luminant Power implementation of the generic SAS design has been integrated into the Emergency Response Facility Computer System (ERFCS). The following discussion serves as a general description of the SPDS portion of the ERFCS.

1. General Considerations

The ERFCS satisfies the requirements of the Safety Parameter Display System (SPDS). This section describes the portion of the ERFCS which meets the SPDS requirements of NUREG-0696 and the intent of NUREG-0737 Supplement 1. The ERFCS provides a centralized, flexible, computer-based data and display system to assist control room personnel in evaluating the safety status of the plant. This assistance is accomplished by providing the operator and also Emergency Response Facilities (ERFs) a high-level graphical display containing a minimum set of key plant parameters representative of the plant safety status. More detailed plant information is provided by several secondary displays. All graphical displays are presented to the control room operator on high resolution multiple color monitors.

All data displayed by the SPDS is validated by comparing redundant sensors, checking the value against reasonable limits, calculating rates of change, and/or checking temperature versus pressure curves.

All displays on the SPDS have been carefully designed by persons with plant operating experience and evaluated against human factors design criteria. The intent of the SPDS is to present to the control room personnel a few easily understandable displays which use color coding and pattern recognition techniques to indicate off-normal values.

These displays are updated and validated on an essentially real-time basis.

The SPDS will be operable during normal and abnormal plant operating conditions. The SPDS will operate during all SPDS required modes of plant operation. The normal operation mode will encompass all plant conditions at or above normal operating pressure and temperature. When the reactor coolant system is intentionally cooled below normal operating values, the operator will select the Heatup-Cooldown mode which alters the limit checking algorithm for the key parameters. An additional mode may be provided to address concerns of cold shutdown plant conditions.

2. Display Hardware Locations and Operation

The SPDS portion of the ERFCS has been incorporated on every Plant Computer workstation located in controlled locations of the control room visible to the control room operator and the Senior Reactor Operator. Every Plant Computer workstation contains the high-level display from which the overall safety status of the plant may be assessed. The standard Human-Machine Interface package located on every Plant Computer workstation allows operator selection of several predetermined second level (trend) displays at any time.

The SPDS has been designed such that control room personnel can utilize its features without requiring additional operations personnel.

The SPDS displays have been provided to other ERFs, such as the Technical Support Center and Emergency Operations Facility.

3. Display Contents

The primary display consists of bar graphs of selected parameter values, digital status indicators for important safety system parameters and digital values. The parameters indicated by bar graphs and digital values include: RCS pressure, RCS temperature, pressurizer level, steam generator levels and steam generator pressures. Status indicators are provided for containment environment, secondary system radiation, and reactor vessel water level. Core exit temperature, amount of subcooling and containment radiation are indicated by digital values.

In addition, there is a message area which will be used to indicate that an appropriate secondary display provides further information in case an off-normal value is detected or an event is occurring.

Each of the bar graphs indicate wide-range values. If a parameter's value is outside the normal range, the bar color will turn yellow, then red. Arrows next to

the bar indicate the trend direction (increasing or decreasing) based on data smoothing algorithms.

Secondary displays may be selected by the operator. Trend graph groups of selected parameters, showing the last thirty minutes of plant operation are available. These trend groupings were chosen to keep like parameters or related parameters on one display "page."

4. Human Factor Engineering

Human factors engineering and industrial design techniques have been effectively combined to establish man-machine interface design requirements, maximize system effectiveness, reduce training and skill demands, and minimize operator error.

The monitor color graphic formats and functional keyboard designs have been developed through an interdisciplinary team of senior operational, human factors, industrial design and computer interface personnel.

Minimum use of color combined with simplified format through the monitor presentation have key design features to provide both normal and off-normal pattern recognition. The operator, who is the end user, has been directly involved from the conception to insure that man-machine interface goals of SPDS have been satisfied. Human factor engineering standards and testing verification have been used which are consistent with accepted practices.

5. Validation and Verification

The SPDS is implemented on a digital computer system which includes a peripheral display generator computer for color graphic displays. The software that controls the sensor data validation, key parameter construction, and display formats has been developed under a software quality assurance program based on guidance from ASME NQA-1 Subpart 2.7. Verification and validation activities have been performed on the system using NSAC-39, ANSI/ANS 10.4-1987, and IEEE 1012-1986 as guidelines.

F. DESIGN CRITERIA

The total SPDS will not be Class 1E or meet the single-failure criterion. The sensors and signal conditioners (such as preamplifiers, isolation devices, etc.) will be designed and qualified to meet Class 1E standards for those SPDS parameters that are also used by safety systems.

The control room operating staff will be provided with sufficient information and criteria to allow for performance of an operability evaluation of SPDS if an earthquake should occur.

The SPDS, as used in the control room, will be designed to an operational unavailability goal of 0.01. The cold shutdown unavailability goal for the SPDS during the cold shutdown and refueling modes for the reactor will be 0.2.

The unavailability goal of 0.01 is more stringent than can be reasonably achieved without some redundancy. Therefore, dual processing nodes in a Primary/Backup configuration, data multiplexors, and other critical peripherals have been installed.

The isolation of the SPDS from safety-related devices is described as follows for each type of safety-related device that has input to the SPDS computer system (e.g. multiplexed analog and digital inputs, core cooling monitor inputs, radiation monitoring system inputs, reactor vessel level indicaiton system inputs).

1. Multiplexed analog and digital inputs are obtained from various systems throughout the plant (e.g., analog signals from tank levels, system pressures, flow rates, etc., digital signals from valve postion, breaker position, etc.). All multiplexed inputs from safety-related devices are routed to their respective (Train A or B) qualified multiplexer cabinets (MUX) located in the environmentally protected cable spreading room. Since the signals from safety-related devices are utilized in the non-qualified Plant Computer System (ERFCS, SPDS), an appropriate qualified isolation device was chosen that would electrically isolate signals from qualified SSCs from the Plant Computer System. All credible adverse conditions were considered and tested per specifications given in the qualification test reports. The isolation devices are in compliance with applicable NRC guidelines and IEEE standards for environmental and seismic qualification, and the PCS isolators are designed and qualified for fail-safe operation.

2. Inputs to the SPDS from the core exit thermocouples and the margin to saturation indicator are by way of the two (Train A and B) qualified safety-related Core Cooling Monitors (CCMs). Electrical isolation between the CCMs and the SPDS is accomplished by means of dc to dc converters and optical isolators. DC to dc converters provide isolated dc power to the non-Class 1E CCM circuits by isolating the Class 1E power supply from the non-Class 1E circuits. Optical isolators provide electrical isolation between the Class 1E input signal circuitry and the non-Class 1E output signal circuitry. Testing was performed to verify that the input side of the isolator suffered no degradation as a result of faults applied to the isolator output. The application of the maximum credible fault voltage and current meets this criterion, thus assuring the adequacy of the dc to dc converter and optical isolator as an isolation device for this application. Adequacy was determined by vendor testing, which is documented in Reference [2].

3. All inputs to the SPDS from the Radiation Monitoring System (RMS) are transmitted as ASCII data from the RMS computer system, except for containment radiation inputs which are routed to the multiplexers as described in Item 1. The RMS computers are non-safety-related devices; therefore, no provision for electrical isolation between them and the SPDS is required.

4. All inputs to the SPDS from the qualified Reactor Vessel Level Indication System (RVLIS) are transmitted as ASCII data through an FOC data link from the qualified, safety-related RVLIS cabinet to the SPDS computer system. All credible adverse conditions were considered and tested per specifications given in the qualification test reports. The isolation devices are in compliance with applicable NRC guidelines and IEEE standards for environmental and seismic qualification, and the entire RVLIS system is designed for fail-safe operation.

The power supply will be from Non-1E Battery, UPS supply.

Expandability in both numbers of parameters and processing power will be provided.

Verification and validation are applied as appropriate.

VIII. INTEGRATED ERF COMPUTER SYSTEM

A. GENERAL DESCRIPTION

In general, the CPNPP integrated ERF computer system consists of a system configuration as shown in Figure III.A.1.2-2. The overall system principally consists of:

1. Data Acquisition System (DAS) units that isolate, digitize, and transmit field sensor signals to the ERF computers.

2. Redundant processing nodes will provide the data processing/distribution/ and record keeping functions required. The processing nodes will be powered from a highly reliable Non-1E Battery/UPS System.

3. For each unit the Human/Machine Interface (HMI) network will consist of sixteen (16) PCS workstations which implement the ERF/SPDS displays generated by the Westinghouse Ad-hoc Safety Assessment System Group. Nine workstations including four monitors on the Main Control Boards will be located in the control room, four in the TSC, and three in the EOF. All of the workstations will have full functional capability to display ERF/SPDS/Plant parameters and displays. The control room, and two of the TSC workstations will be powered from Non-1E, Battery/UPS power supplies. The rest of the workstations are powered from a Non-Class 1E 120 VAC common supply.

   The integrated ERF Computer System reliability design goal is to achieve 0.01 unavailability during all plant operating modes above cold shutdowns.

B. IMPLEMENTING SCHEDULE

The ERF Computer hardware and software was installed with a sufficient set of input variables to accomplish the SPDS and Regulatory Guide 1.23 functions by fuel load.

III.A.2 IMPROVING LICENSEE EMERGENCY PREPAREDNESS--LONG TERM

OBJECTIVE:

To upgrade the emergency preparedness of nuclear power plants.

- NUREG 0660

Action Plan Requirements:

Each nuclear facility shall upgrade its emergency plans to provide reasonable assurance that adequate protective measures can and will be taken in the event of a radiological emergency. Specific criteria to meet this requirement is delineated in NUREG-0654 (FEMA-REP-1), “Criteria for Preparation and Evaluation of Radiological Emergency Response Plans and Preparation in Support of Nuclear Power Plants.”

- NUREG 0737

CPNPP Response

The CPNPP Emergency Plan is currently being revised to reflect requirements expressed in NUREG-0654, Revision 1. Equipment, facilities and instruments necessary to implement the Emergency Plan are subject to an Operations Quality Assurance Program. Activities necessary to implement the Emergency Plan are controlled by approved procedures and subject to the proper QA controls and surveillances.

Prior to fuel load of Unit One, the meteorological measurements program for CPNPP shall consist of the following:

1) A primary meteorological measurements program;

2) A backup meteorological measurements system;

3) A system for making near real-time predictions of the atmospheric effluent transport and diffusion;

4) A capability for remote interrogation, on demand, of the atmospheric measurements and prediction systems by CPNPP emergency response organizations and the NRC staff.

III.A.3 IMPROVING NRC EMERGENCY PREPAREDNESS

OBJECTIVE:

To enable NRC, in the event of a nuclear accident at a licensed reactor facility, to (1) monitor and evaluate the situation and potential hazards, (2) advise the licensee’s operating staff as needed, and (3) in an extreme case, be able to issue orders governing such operations.

III.A.3.3 Communications

Action Plan Requirements

Install direct dedicated telephone lines between each plant and the NRC Operations Center.

- NUREG 0694, Pg. 27

CPNPP Response

The Federal Telecommunications System (FTS) 2000 network has been installed at CPNPP for communications with the NRC Operations Center.

III.D RADIATION PROTECTION

III.D.1 RADIATION SOURCE CONTROL

OBJECTIVE:

"Perform evaluations to establish additional design features that should be included in the rulemaking proceeding of Item II.B.8. The purpose of these evaluations is to identify design features that will reduce the potential for exposure to workers at nuclear power plants and to offsite populations following an accident."

-NUREG 0660, Pg. III.D.1-1

III.D.1.1 Primary Coolant Sources Outside The Containment Structure

Action Plan Requirements:

"Applicants shall implement a program to reduce leakage from systems outside containment that would or could contain highly radioactive fluids during a serious transient or accident to as-low-as-practical levels. This program shall include the following:

(1) Immediate leak reduction

(a) Implement all practical leak reduction measures for all systems that could carry radioactive fluid outside of containment.

(b) Measure actual leakage rates with system in operation and report them to the NRC.

"(2) Continuing Leak Reduction -- Establish and implement a program of preventive maintenance to reduce leakage to as-low-as-practical levels. This program shall include periodic integrated leak tests as intervals not to exceed each refueling cycle."

- NUREG 0737

CPNPP Response

The residual heat removal (RHR) system; portions of the containment spray (CS) system; portions of the safety injection (SI) system; portions of the chemical and volume control (CVCS) system and the RCS Sampling System (post accident sampling system portion only until such time as a modification eliminates the PASS penetration as a potential leakage path) have been identified as systems which process primary coolant, and could contain high level radioactive materials. (See Section II.B.2.2.) Programs will be implemented to reduce and maintain leakage to as-low-as-practical levels. These programs will include but not be limited to the requirements of the ASME Boiler and Pressure Vessel Code, Section XI.

1. The RHR, CS, SI, and CVCS systems are ASME Code Class 2 and 3, and are subject to the in-service inspection requirements of the ASME Boiler and Pressure Vessel Code, Section XI, including pressure tests.

2. At intervals not exceeding refueling outages, Radioactive System Leakage Inspection (RSLI) tests will be performed on appropriate portions of the RHR, SI, CS, CVCS and RCS Sampling Systems.

3. Excessive leakage into controlled areas will also be indicated by abnormally high airborne radioactivity levels.

4. Plant Initial Leakage Rates

   The initial leakage rates of the system to be tested will be determined from the system hydrostatic (or pneumatic) test which is conducted prior to plant operations and/or the initial Radioactive System Leakage Inspection (RSLI) test.

5. Test Methods

   The primary testing method will be by system walkdown while at normal operating pressure with quantified measurements obtained at all visually observed leakage paths. Systems or subsystems not readily testable in this manner will require either leakage makeup to maintain test pressure testing or pressure drop testing. Actual testing experience may suggest alternate methods which may be incorporated.

6. Limiting Leakage Value

   The effort at CPNPP will be to minimize the overall leakage of fluid from potentially radioactive systems to the environment. Therefore, the limiting leakage value will be based on a cumulative total of the systems within each Unit. The leakage will be limited to a maximum of 1 gpm/Unit.

7. Maintaining Leakage Value

   While shutdown or during operations, the affected systems will receive a periodic inspection for leakage at intervals not to exceed each refueling cycle. The leak tests will be scheduled to coincide with routine system operability tests whenever possible during operations. To minimize the actual leakage rate, packings or seals with provisions for adjustment will be adjusted whenever leakage is noted during the inspection. Replacements of seals, gaskets, o-rings, etc., will be accomplished on a selective basis to prevent exceeding the limiting leakage value.

   Should the limiting leakage value be exceeded, a reinspection and leak test will be conducted on the system(s) with high leakage rates. Excessive leakage paths will be identified and evaluated. Areas of continued high leakage will be considered for modification or improvement in repair methods.

   Modifications or repairs will be accomplished as quickly as possible. Consideration as to the type of leakage, fluid involved, leakage location and collectability will influence repair or modification schedules.

8. Incidence of Leakage at North Anna

A reviews and comparison of the designs of North Anna and Comanche Peak as pertains to the leakage incidence indicates that the design of the Comanche Peak volume control tank relief system is sufficiently different to preclude a similar occurrence. In addition a further review of procedures and as-built configurations will be performed as they become available. Areas or activities which could result in release of radioactive material will be evaluated for modification.

III.D.3 WORKER RADIATION PROTECTION IMPROVEMENT

OBJECTIVES:

“Improve nuclear power plant worker radiation protection to allow workers to take effective action to control the course and consequences of an accident, as well as to keep exposures as low as reasonably achievable (ALARA) during normal operation and accidents, by improving radiation protection plans, health physics, inplant radiation monitoring, control room habitability, and radiation worker exposure data base.”

III.D.3.3 Improved Inplant Iodine Instrumentation Under Accident Conditions

Action Plan Requirements:

"(1) Each licensee shall provide equipment and associated training and procedures for accurately determining the airborne iodine concentration in areas within the facility where plant personnel may be present during an accident.

"(2) Each applicant for a fuel-loading license to be issued prior to January 1, 1981 shall provide the equipment, training, and procedures necessary to accurately determine the presence of airborne radioiodine in areas within the plant where plant personnel may be present during an accident.”

- NUREG 0737

CPNPP Response

An in-plant radiation monitoring program shall be established, implemented and maintained to ensure the capability to accurately determine the airborne/iodine concentration in vital areas under accident conditions. This program shall include provisions for the training of personnel, procedures for monitoring, and provisions for maintenance of sampling and analysis equipment.

During accident conditions portable grab sampling equipment will be used to obtain iodine samples. These samples may be taken in all areas occupied by plant personnel.

The portable grab sampling equipment used consists of a high volume air sampler, a sample cartridge head and a silver zeolite iodine cartridge. This equipment is identical to the equipment normally used for routine iodine sampling. The only difference is the type of collection media used (silver zeolite versus charcoal).

After the iodine sample is obtained, the silver zeolite cartridge will be surveyed and counted in accordance with applicable Emergency Plan Procedures. Specific calculations contained in these procedures will allow personnel taking samples to determine if iodines are present. All used silver zeolite cartidges will be properly labeled, bagged and retained for further analysis, if required. Should additional analysis be required, the selected samples will be transported to the Chemistry Hot Lab. In the Hot Lab, the silver zeolite cartridges will be prepared for counting, then transferred to the Counting Room for isotopic analysis.

In the Counting Room, the silver zeolite cartridge will be counted on a Gamma Spectroscopy System consisting of: a HPGe detector, Multi-Channel Analyzer and Process Computer. The process computer identifies the iodine isotopes present, performs the calculations, and prints out a listing of all iodine isotopes identified along with their respective concentrations.

Several other lab facilities can be made available on short notice to provide back-up radiological analysis of post accident samples. These other facilities are listed in Section 6.8 of the CPNPP Emergency Plan. Availability and location of non-portable radiation detection/measuring equipment is listed in FSAR Table 12.5-1. Both stationary and portable monitors are commercial grade, and subject to an appropriate Operations QA Program.

All procedures and instructions associated with in-plant iodine monitoring under accident conditions shall be prepared, approved, and implemented prior to Unit 1 fuel load.

All training programs and procedures associated with sample acquisition, sample quantification and data evaluation pertaining to in-plant iodine monitoring activities under accident conditions shall be prepared, approved, and implemented prior to Unit 1 fuel load.

III.D.3.4 Control Room Habitability Requirements

Action Plan Requirements:

“In accordance with Task Action Plan item III.D.3.4 and control room habitability, licensees shall assure that control room operators will be adequately protected against the effects of accidental release of toxic and radioactive gases and that the nuclear power plant can be safely operated or shut down under design basis accident conditions (Criterion 19, “Control Room,” of Appendix A, “General Design Criteria for Nuclear Power Plants,” to 10 CFR Part 50).”

- NUREG 0737

CPNPP Response

A reevaluation of control room habitability has been performed.

Sections 2.2.1, 2.2.2, 2.2.3 and 6.4 of the Standard Review Plan (SRP) were reviewed for compliance and are discussed as follows:

1) FSAR Sections 2.2.1 and 2.2.2 is in compliance with SRP Sections 2.2.1 and 2.2.2.

2) FSAR Section 2.2.3 is in compliance with SRP Section 2.2.3.

3) FSAR Section 6.4 shows that the present CPNPP design for the control room is in compliance with SRP Section 6.4. An analysis was performed to evaluate the effect of a postulated steam generator blowdown piping break in the Electrical and Control Building on the Control Room. The results of the analysis indicate that the Control Room is not affected.

Information required by NUREG-0737, III.D.3.4, Attachment 1, is provided below:

(1) The control room ventilation mode of operation for radiological accident isolation is described in FSAR Section 6.4.2.

(2) Control room characteristics

(a) The control room air volume is provided in FSAR Section 15.6.5.4 (item 4(j)).

(b) The control room envelope (i.e., emergency zone) is described in FSAR Section 6.4.

(c) The control room ventilation system schematic is provided by FSAR Figure 9.4-1.

(d) Control room infiltration leakage is discussed in FSAR Sections 6.4.2.3 and 9.4.1.2.

(e) HEPA filter and charcoal adsorber efficiencies are provided in FSAR Section 15.6.5.4 (item 4(b)).

(f) The distance between the containment and air intake is provided in FSAR Section 15.6.5.4 (item 4(g)).

(g) Layouts are provided in FSAR Figures 1.2-1, 1.2-33, 1.2-34 and 6.4-3.

(h) Control room shielding is discussed in FSAR Section 6.4.2.5.

(i) Automatic isolation capability is discussed in FSAR Sections 6.4.2.2 and 9.4.1.2.

(j) Toxic chemicals are discussed in FSAR Section 2.2.3.

(k) Portable self-contained breathing apparatus (SCBA) are provided in the control room. There will be an adequate supply of air to sustain the five-man emergency team for a six-hour period. At least one SCBA will be provided for each member of the emergency team. There will be one additional SCBA to serve as a spare in case one unit fails.

(l) Bottled air supplys are discussed in FSAR Section 6.4.1.3.

(m) Emergency food and water supplies are provided in FSAR Section 6.4.1.1.

(n) The Shift Manager controls the number of personnel allowed into the control room during both normal and emergency conditions. The personnel capacity is

dependent on specific conditions at the time in question. The minimum capacity under design basis accident conditions is five men for a period of five days.

(o) Potassium iodide (KI) will be available to plant emergency personnel. The details of KI use and availability are controlled in accordance with provisions of the CPNPP Emergency Plan.

(3) Onsite Storage of Chlorine and Other Hazardous Chemicals

Toxic chemicals as discussed in FSAR Section 2.2.3.

(4) Offsite manufacturing, storage, or transportation facilities of hazardous chemicals is discussed in FSAR Section 2.2.

(5) Technical Specifications for CPNPP will comply with the Standard Technical Specifications for Westinghouse Pressurized Water Reactors (NUREG-0452) for the control room emergency filtration.

Items described in this response are listed, as appropriate, in Table 17A-1 under Items 23, 36, 37, 38 and 41.

COMANCHE PEAK NUCLEAR POWER PLANT
FINAL SAFETY ANALYSIS REPORT (FSAR)

PREFACE

The Effective Page Listing indicates which pages, tables and figures are current in the CPNPP/ FSAR. All pages/sheets within a FSAR section or FSAR table have an amendment number in the footer. Each sheet of a FSAR figure, which is not an “M” or “E” series station drawing, will be identified with an individual amendment number, date or “original”. The effective revision number and amendment number for “M” or “E” series figures in the FSAR are identified in Table 3.2-3. FSAR Amendment numbers are not shown on “E” and “M” series figures themselves, and the current versions are identified by revision number only.

In the EPL, a table number is preceded by a "T" (e.g., "T1.3-1") and a figure is preceded by an "F" (e.g., "F9.1-3"). Text portions of the FSAR are identified by section number only (e.g., “Section 5.4”).

For text and tables, the amendment number and/or date is generally located at the bottom of the sheet, near the margin. For non “E” and “M” series figures, the amendment number and/or date is generally located in the vicinity of the title block for that figure.

BELOW IS A LISTING OF ALL FSAR AMENDMENT NUMBERS AND DATES:

ORIGINAL	Submitted February 27, 1978
MARCH 21, 1978	Update
AMENDMENT 1	June 15, 1978
AMENDMENT 2	July 27, 1978
AMENDMENT 3	November 30, 1978
AMENDMENT 4	January 31, 1979
AMENDMENT 5	March 30, 1979
AMENDMENT 6	May 31, 1979
AMENDMENT 7	July 31, 1979
AMENDMENT 8	November 30, 1979

FSAR Amendment 100, Supplement a

LDCR-SA-2006-12 (RAS):

Administrative change for software conversion only. The changes are editorial in nature and contain no technical changes. The electronic files have been converted from Microsoft WORD to Adobe FrameMaker and published in Adobe Portable Document Format (pdf). The type of changes include changes such (1) correction of spelling errors, (2) correction of inadvertent word processing errors from previous changes, and (3) style guide changes (e.g., changing from a numbered bullet list to an alphabetized bullet list and vice versa, change numbering of footnote naming scheme). The entire FSAR will be reissued as Amendment 100, Supplement a except as noted below. For the text and tables there will be no change bars in the page margins for the editorial changes. The list of effective pages is being replaced with a list of effective sections, tables, and figures. Some Figures and Tables will retain an Amendment number prior to Amendment 100 since the source file is not in Adobe FrameMaker (e.g., scanned page).

Sections Revised: All

Tables Revised: All (except as noted above)

Figures Revised: All (except as noted above)

FSAR Amendment 100, Supplement b

LDCR-SA-2005-8, EVAL-2003-002423-02 (DWS):

Table 17A-1, sheets 45, 53 & 58

Revise the Q-List criteria to add instrument tubing that is connected to ANSI Safety Class 3 ductwork to clarify that criteria appropriate for the application is not the same as for ASME applications covered by FSAR Section 3.9B.3.4.3.

Although not included in commitment CDF-22112, FSAR Table 17A-1 previously applied the same criteria for instruments connected to Safety Class 3 HVAC ductwork as for ASME piping. The change to Table 17A-1 would document that this very conservative practice may be continued; however, it is not required. The tubing should only have to meet the seismic requirements comparable to the equipment to which it is connected.

Section 9.4: FSAR Figure 9.4-9 is revised to show the impulse lines to the non-safety instruments on the Non-ESF PPVES units are being declassified to NNS. This would allow seismic Category II supports rather than seismic Category I supports.

Where the tubing is reclassified as NNS in accordance with ANSI N18.2 [as described in DBD-ME-028], the instrument should only have to meet the requirements of the tubing. FSAR Figure 9.4-9 is revised to show the impulse lines to the non-safety instruments on the Non-ESF PPVES units are being declassified to NNS based on no credible failure which could adversely affect the Nuclear Safety Function of the PPVES.

LDCR-SA-2005-22, EVAL-2005-002874-01 (DWS):

Section 17.2.12

Revise paragraph on M&TE and reference standards to indicate the standards are traceable to nationally and internationally recognized standards. National laboratories no longer support all types of calibration.

NUREG-0800 Standard Review Plan Section 7.1 "Instrumentation and Controls - Introduction" endorses Branch Technical Position HICB-12 "Guidance on Establishing and Maintaining Instrument Setpoints" which endorses ANSI/NCSL Z540-1-1994 "American National Standard for Calibration _ Calibration Laboratories and Measuring and Test Equipment _ General Requirements".

ANSI/NCSL Z540-1-1994 Section 9.2 states in part ".....measurements made by the laboratory are traceable to national, international, or intrinsic standards....

LDCR-SA-2005-22, EVAL-2005-002874-01 (DWS) (continued):

Section 1A(B) - Regulatory Guide 1.30

NUREG-0800 Standard Review Plan Section 7.1 "Instrumentation and Controls - Introduction" endorses Branch Technical Position HICB-12 "Guidance on Establishing and Maintaining Instrument Setpoints" which endorses ANSI/NCSL Z540-1-1994 "American National Standard for Calibration _ Calibration Laboratories and Measuring and Test Equipment _ General Requirements".

ANSI/NCSL Z540-1-1994 Section 9.2 states in part ".....measurements made by the laboratory are traceable to national, international, or intrinsic standards...."

LDCR-SA-2005-33, EVAL-2004-003442-01 (DWS):

Delete from Section FSAR 17.2.1.3.2 and 17.2.18.2 as follows "For audits other that those audit areas with a maximum frequency specified by regulation (Security, Emergency Planning, (Delete "and Radiation Protection") a grace period.....

Historically the periodic review described in 10CFR20.1101(c) has been satisfied by an independent quality assurance audit. This annual review will be satisfied as described below and every 24 months a quality assurance audit will be performed which is consistent with ANSI N18.7 sect 4.5

NOD Audits (which usually include industry peers)

* NOD currently performs annual audits.

NOD Surveillances

Manager and Supervisory Observations (LEADING)

Annual performance reviews

Corrective Action Program (documentation of procedural noncompliance in SmartForms)

RP Self- Assessments (which may include industry peers or contractors)

Third Party Audits (NRC, INPO, NVLAP and ANI)

FSAR Amendment 100, Supplement b

LDCR-SA-2006-11, EVAL-2006-000798-01 (DWS):

Section 17.2: Revise ORC membership composure, definition of a ORC quorum, and audit functions. Move audits listed under Section 17.2.1.3.2 to Section 17.2.18

This is an administrative change only and is in compliance with the requirements of ANSI N18.7-1976.

LDCR-SA-2006-16, EVAL-2006-001294-01 (DWS):

Section 17.2: Add statement "TXU Power may delegate to others such as contractors, agents, or consultants the work of establishing and executing the quality assurance program, or any part thereof". And clarify QA responsibilities on page 21, 23, 28 and 29.

Title 10, Code of Federal Regulations, Part 50, Appendix B, "Quality Assurance Criteria for Nuclear Power Plants and Fuel Processing Plants," allows the use of contractors to perform QA functions as long as the overall responsibility for the Quality Assurance (QA) Program remains with the Senior Vice President & Chief Nuclear Officer.

LDCR-SA-2006-9, EVAL-2005-003061-02 (DWS):

Section 17.2: Revise composure of the Station Operations Review Committee (SORC) and current organizational positions. Replace "Vice President, Nuclear Engineering" with "Vice President, Nuclear Engineering and Support" wherever it appears. Replace "Vice President, Nuclear Operations" with "Site Vice President" wherever it appears. Define the responsibilities of the Site Vice President and Plant Manager. Delete some references to Section 13.1.1.2.1. Insert Figure 13.1-2 and 13.1-3 for Figures 17.2-1 and 17.2-2.

Revised composure of SORC will reflect current organizational changes. This would resolve the discrepancy between current directors and the generic title of managers, clearly indicate the minimum number of SORC members and clarify that the listed individuals are in areas of experience, not organizational or position titles.

LDCR-SA-2006-14, EVAL-2006-001365-01 (DWS):

Section 17.2.1.3.1: Revise FSAR Section 17.2.1.3.1 to delete ORC review of changes to the Technical Specifications or the Operating License. Move this review requirement to Quality Assurance FSAR Section 17.2.1.6

American National Standard N18.7-1976/ANS-3.2, Section 4.3 requires the independent review of operational activities and allows these activities to be performed either by a Standing Committee (ORC) (Section 4.3.2) or by Organizational Units (Section 4.3.3). This change deletes the use of ORC for review of changes to the Technical Specifications or Operating License and incorporates the alternative method of using Organizational Units to perform the Independent Review.

FSAR Amendment 100, Supplement b

LDCR-SA-2006-22, EVAL-2006-002136-01 (DWS):

17.2.1.1.3.1 change reference for required experience from ANSI N18.1-1971 to Regulatory Guide 1.8, Rev.2. The RG is a higher tier document, therefore there is no change in commitment.

17.2.1.3 change reference to items "a through h" above to "1 through 9". This is editorial only to match the new format.

17.2.3 remove requirement for ORC approval before proceeding with implementation of TS changes or other changes to the operating license. This change was approved in LDCR SA-2006-14, however, this section did not reflect the change.

17.2.6.1 "Number second paragraph "6" and reformat bullets under this paragraph from "1 & 2" to "a & b". This is editorial only to match the new format and eliminate redundant numbering under same section.

LDCR-SA-2004-36, EVAL-2001-002847-05 (CBC):

EVAL-2001-002847-05 (LDCR-SA-2004-036) / Sections 1.2.2.3.7, 6.4.1.2, 6.4.2.2, 6.4.2.3, 6.4.2.4, T6.4-1 (Sheet 1), 9.4.1.1, 9.4.1.2, 9.4.1.3, 9.4.1.4, T9.4-10 (Sheet 1 - item 2.a) (Sheet 2 - items 2.c, 2.e) (Sheet 3 -item 2.f), 15.6.5.4: Per FSAR Section 9.4 and 6.5, the basic design functions of the inlet dampers associated with each Train of Control Room (CR) HVAC ventilation system are to: (1) open and let air into the CR via the ventilation system and to (2) close to isolate the CR ventilation system from outside air. The existing dampers do not perform this 2nd function as readily as desired as tracer gas testing has demonstrated some filtered in-leakage occurs when the ESF systems are lined up to operate in emergency modes.

Replacing the existing dampers with bubble tight dampers will minimize the amount of filtered in-leakage into the CRE when operating in emergency modes and one of the Trains of CR HVAC is shutdown. This activity does not change the original design functions of the individual dampers and thus, will not change the design function of the CR HVAC System.

LDCR-SA-2004-036 updates the FSAR providing information for the new type of dampers and their associated design functions of ensuring the assumptions made in the dose analyses remain valid and in accordance with the original design function of the CR HVAC system.

EVAL-2001-002847-05 (LDCR-SA-2004-036) / Section 9.4.1.1: The word "inoperative" is replace with the word "inoperable." This is an editorial clarification.

EVAL-2001-002847-05 (LDCR-SA-2004-036) / Section 9.4.1.2: Replace "resistand with "resistan." This is an editorial correction.

EVAL-2001-002847-05 (LDCR-SA-2004-036) / Section 9.4.1.2: Replace "The main toilet" with "The toilet". This is an editorial clarification.

LDCR-SA-2004-36, EVAL-2001-002847-05 (CBC) (continued):

EVAL-2001-002847-05 (LDCR-SA-2004-036) / Section9.4.1.3: Per FSAR Section 9.4.

LDCR-SA-2005-18, EVAL-2001-002657-03 (CBC):

Section 9.1.4.2.3(14): Revise Section 9.1.4.2.3(14), "Fuel Handling System / System Description / Component Description / Polar Crane," to clarify operation of the polar crane during MODES 1 through 4. Previously the FSAR indicated the crane remained essentially in the parked position during MODES 1 and 2 and the crane may be operated through its full 360 degree travel range during MODES 3 and 4. The revised discussion indicates the crane remains essentially in the parked position during MODES 1 through 4 unless maintenance is being performed on it. The Containment Access Rotating Platform is allowed to be used for maintenance on (including modifications to) the Polar Crane in MODES 1 through 4. During Polar Crane maintenance the polar crane may be operating through its full 360 degree travel range. This change is acceptable since any maintenance activities performed on the polar crane (including its movement) during MODES 1 through 4 are subject to risk assessments performed in accordance with the maintenance rule 10CFR50.65(a)(4).

The phrase "...any safety related SSC (e.g., Hydrogen Recombiner)." is changed to "... any safety related SSC." This excessive level of detail is not required for the FSAR.

Change the phrase "No load will be carried during MODES 1-4." to "No load will be carried by the polar crane during MODES 1-4." This consistent with the changes above.

The phrase "A compensatory measure (operator, in direct communication..." is changed to "A compensatory measure (a dedicated person, ...". An operator is not required for this administrative function.

LDCR-SA-2005-20, EVAL-2005-003243-01 (CBC):

Section 9.1.4.2.3: EVAL-2005-003243-01 / LDCR-SA-2005-20: Changes description in FSAR Section 9.1.4.2.3, "Fuel Handling System / System Description / Component Description / Reactor Vessel Stud Tensioner," by revising the discussion of the stud tensioning process for the reactor vessel head. The method used to pretension the reactor vessel head studs has changed. The requirement that the tensioning method prevent unequal loading of the studs and excessive stress in the flange region remains unchanged, therefore the change is acceptable. The old description contained excessive detail and has been deleted and a statement added that an approved sequence is used to tension the studs.

LDCR-SA-2005-28, EVAL-2004-002831-04 (CBC):

This change to Section 9.1.4.2.3(4) allows the new fuel elevator to also be used in the reconstitution of irradiated fuel. The new fuel elevator will have mechanical stops added that will not adversely affect the elevator's design and its electrical limit switches readjusted to ensure the 10 feet of water shielding is maintained during fuel

LDCR-SA-2005-28, EVAL-2004-002831-04 (CBC) (continued):

reconstitution. During normal operation the mechanical stops are removed and electrical limits will be reset, allowing the new fuel elevator to lower new fuel into the cask pit area. The addition of the mechanical and electrical stops will have no adverse impact on any SSC design function.

LDCR-SA-2005-31, EVAL-2001-001914-14 (CBC):

Section 8.2.1: In Section 8.2.1, revise the stated use of Spare Startup Transformer XST1/2 to be a physical replacement of Startup Transformer XST2 instead of being energized at its storage location west of the Turbine Building from the 345 kV line by closing a normally open motor-operated air-switch. The description of the physical relocation of Spare Transformer XST1/2 and connection to the 138 kV line to XST1 has not changed. Spare Startup Transformer XST1/2 is presently located west of the Turbine Building across the access road under the 345 kV line feeding Station Service Transformer 1ST and Startup Transformer XST2. The Spare Transformer high voltage bushings are connected thorough a motor-operated air-switch to the 345 kV line. The air switch is locked open. The original intent was to use the Spare Transformer from this location in the event of a failure of Startup Transformer XST2 by building a 6.9 kV cable bus across the access road and into the TB for temporary connection into the plant 6.9 kV cable bus system. However, a more practical use of Spare Transformer XST1/2 in the event of a failure of XST2 is to physically move out XST2 and place the Spare Transformer on the XST2 pad.

This allows the 6.9 kV secondary cable bus to be directly connected to the Spare Transformer without modification of the secondary cable bus. The space between the 6.9 kV bushing phases and their height is exactly the same for both transformers. The only modification required is to identify the alternate terminations for power, control and protective relay circuits. FDA-2001-001914-16 is a paper change only contingency modification providing alternate connections for Spare Transformer XST1/2 when physically replacing Startup Transformer XST2. This change to the FSAR more accurately describes the use of Spare Transformer XST1/2 in the physical replacement of XST2.

LDCR-SA-2004-19, EVAL-1999-003133-08 (CBC):

Section 3.3.2.2, 9.4C.2, and 9.4C.3: Revise description of Section 3.3.2.2 , " Tornado Protection Design Features - Tornado Pressure Relief Dampers In Interior Fire Walls", Section 9.4C.2 " Main Steam and Feedwater Piping Area Ventilation System", Section 9.4C.3 " Electrical Area (Safeguards) Ventilation System"

The Safeguards Electrical Area Ventilation System (EAVS) may not be able to maintain the minimum design and licensing limiting temperature in the MS/FW Pipe & Electrical Area HVAC Room rooms 1-104 and 2-104, during extreme wintertime conditions. The Main Steam and Feedwater (MS & FW) Area Ventilation System may not be able to maintain the maximum design and licensing limiting temperature in the Main Steam and

LDCR-SA-2004-19, EVAL-1999-003133-08 (CBC) (continued):

Feedwater Pipe Penetration Areas, during extreme summertime conditions. [Reference SMF-1999-003133]

This modification, FDA-1999-003133-01-02, connects the EAVS and MS &FW Area Ventilation Systems in order to enhance the efficiency of each ventilation system in performing its design function. The modified ventilation systems establish new EAVS exhaust air flow paths through the areas served by EAVS. EAVS tempered exhaust air is drawn through a common stairwell, open doors and floor openings from the electrical areas to the fresh air intake of the MS & FW Area Ventilation System air handling unit located in the Mechanical Equipment Room on Elevation 852'-6".

This modification does not result in an adverse impact on the design function both stated and implicit for those plant components, systems, programs and licensing basis requirements impacted by this activity. The activity does not result in an adverse impact to the design functions of SSC's as described in the FSAR.

LDCR-SA-2005-23, EVAL-2002-000747-01 (CBC):

Table 3.9B-10: EVAL-2002-000747-01 (LDCR-SA-2005-23) Revise Table 3.9B-10, "Active Valves" to clarify the method of actuation for LV-4500, LV-4501, and LV-4500-1. Section 9.2.2.5.3 of the FSAR notes the manual operation of the valves as well as the safety function. This is a trivial administrative clarification of a supporting section.

LDCR-SA-2004-43, EVAL-2004-000038-01 (CBC):

Figures 3.6B-64-1 and 3.6B-64-2: EVAL-2004-000038-01 (LDCR-SA-2004-043): Inactive pipe whip restraint RC-1-007-902-C47W is being deleted and removed from the plant. This LDCR will update the Restraint Location drawing in the FSAR to reflect the facilities configuration. The removal of a non-functioning (i.e., abandoned) pipe whip restraint does not result in an adverse impact on the ability of the plant SSC's to mitigate the consequences of a postulated accident. This restraint presents obstructions to outage maintenance activities that result in increased dose and the potential for injury.

LDCR-SA-2005-15, EVAL-2002-004206-03 (RJK):

In FSAR Section 3.6B.2.5.2 the design pressure for the portion of the Unit 1 Safety Injection (SI) System from and including the SI Pumps up to the outside containment isolation valves is being increased from 1750 psig to 1860 psig to resolve discrepancies identified during an NRC SSD&PC Inspection in 2002. The discrepancies identified were that the SI pump shutoff head identified in the FSAR and DBD was less than the maximum shutoff head shown on the vendor certified pump curves.

The Unit 1 system design pressure has been established at 1860 psig to bound the maximum SI pump discharge pressure that could exist following a LOCA and while in the recirculation mode. The system piping and components have been re-evaluated for this higher design pressure. In Table 6.3-2 the relief valve set points have been changed to

LDCR-SA-2005-15, EVAL-2002-004206-03 (RJK) (continued):

1860 psig, i.e., just above the maximum postulated SI pump discharge pressure, to prevent their opening while in the recirculation mode. Increasing the relief valve set points from 1750 psig to 1860 reduces the probability that the valves will open while the SI system is operating in the recirculation mode and, therefore, provides greater assurance that they can perform their function as a boundary for a closed system outside containment.

In Table 6.3-1 the Unit 1 system design pressure has been established at 1860 psig to bound the maximum SI pump discharge pressure that could exist following a LOCA and while in the recirculation mode. The system piping and components have been re-evaluated for this higher design pressure.

LDCR-SA-2005-2, EVAL-2001-001255-12 (TJE):

Sections 8.3.1.1.11.1 and 8.3.1.1.11.2: The changes in sections 8.3.1.1.11.1 and 8.3.1.1.11.2 provide a description of the new Unit 1 Train B upgraded digital excitation/ voltage regulator that will be consistent with the previous digital excitation/voltage regulator modifications on Unit 1 Train A and Unit 2 Trains A and B. See Markup in EVAL-2001-001255-12.

NOTE: The DG Exciter/Voltage Regulator Upgrade/replacement will replace the obsolete Exciter/Voltage Regulator for the Emergency Diesel Generator with a new digital-controlled exciter/voltage regulator which will be able to be serviced and replaced for the next 20 years.

Section 8.3.1.2.1, Part J: The changes in section 8.3.1.2.1 Part J, dealing with Compliance with the NRC Regulatory Guide 1.75, provides a description of the new Unit 1 Train B upgraded digital multifunction protective device that will be consistent with the previous digital multifunction protective device modifications on Unit 1 Train A and Unit 2 Trains A and B. See Markup in EVAL-2001-001255-12.

NOTE: The DG Exciter/Voltage Regulator Upgrade/replacement will replace the obsolete Exciter/Voltage Regulator for the Emergency Diesel Generator with a new digital-controlled exciter/voltage regulator which will be able to be serviced and replaced for the next 20 years.

LDCR-SA-2005-7, EVAL-2001-002847-10 (TJE):

Section 8.3.1.1.11.2: Currently, in section 8.3.1.1.11.2 under Protection Systems the sentence reads, "The valve motors are protected against sustained fault conditions by circuit breakers if full load currents are equal to or greater than 0.66 amps, and by fused disconnect switches if full load currents are less than 0.66 amps."

Change the sentence to read, "The valve motors are protected against sustained fault conditions by circuit breakers. The valve motors may be protected by fused disconnect switches if full load currents are less than 1.3 amps."

LDCR-SA-2005-7, EVAL-2001-002847-10 (TJE) (continued):

This change does not affect the ability of the MOVs to perform their required safety functions. The alternate design allowance for fuse to be used for MOV circuit protection is limited to only a small set of MOVs, originally provided with fuse protection by the MCC vendor, to further reduce the exposure of fuse blowing. As such the alternate design allowance for fuse to be used for MOV circuit protection is acceptable.

Section 8.3.1.2.1.6, Part c.1: Currently, in section 8.3.1.2.1.6 part c.1 the sentence reads, "For all starter circuits feeding motors having full load currents equal to or greater than 0.66A, and for all feeder circuits, a circuit breaker and starter with a thermal overload relay as primary protection in series with a circuit breaker as backup protection or two circuit breakers in series for primary and backup protection are provided in each circuit."

The sentence will be modified to read, "For all starter circuits feeding motors and for all feeder circuits, primary protection is generally provided with a circuit breaker and/or starter with a thermal overload relay in series with a circuit breaker as backup protection or two circuit breakers in series for primary and backup protection are provided in each circuit."

Section 8.3.1.2.1.6, part c.2: Additionally, section 8.3.1.2.1.6 part c.2 reads, "For all starter circuits feeding motors having full load currents less than 0.66A, primary and backup protection is provided by means of a fused disconnect switch and a circuit breaker respectively."

The sentence in c.2 will be modified to read, "For starter circuits feeding motors having full load currents less than 1.3 A, primary and backup protection may be provided by means of a fused disconnect switch and a circuit breaker respectively."

This change does not affect the ability of the MOVs to perform their required safety functions. The alternate design allowance for fuse to be used for MOV circuit protection is limited to only a small set of MOVs, originally provided with fuse protection by the MCC vendor, to further reduce the exposure of fuse blowing. As such the alternate design allowance for fuse to be used for MOV circuit protection is acceptable.

LDCR-SA-2005-10, EVAL-2000-000526-5 (TJE):

Figure 8.3-16: In FSAR Figure 8.3-16, removed unit differences in lower left hand table under titles "NORMAL" and "TOTAL".

Note: The fiber optic modules are installed to support the Wireless LAN Extension into the Unit 1 Containment Building and to support the new Radiation Protection Camera LAN system. The fiber optic modules will not impact the other circuits in the penetrations. FSAR Sections 8.3.1.4.4, 8.3.1.4.5 and 8.3.1.4.10 all state there is no separation required between Non-1E fiber circuits and 1E circuits. Fiber Optic circuits will not interfere with 125 Vdc or 120 Vac circuits in Type 3 Penetrations, nor will the control circuits interfere with the fiber optic circuits. Therefore, there is no concern that the fiber optic will cause a

LDCR-SA-2005-10, EVAL-2000-000526-5 (TJE) (continued):

fire that could damage the other circuits nor will the fiber impair the operation of any other circuits.

LDCR-SA-2005-19, EVAL-2003-001365-14 (TJE):

Section 8.2.1: In section 8.2.1, 1.) add the following sentence to the end of the 11th paragraph, "The network transmission line terminals of 345-kV switchyard are provided with a third set of relay protection to enhance the reliability of transmission system fault isolation."

In section 8.2.1, 2.) add the following sentence to the end of the 12th paragraph, "A separate 125-VDC system is provided for the third set of relay protection in the 345-kV switchyard."

Note: The third scheme of relay protection can provide this last resort backup protection locally, thereby minimizing the impact on the system. This will increase the availability and reliability of the 345kV offsite source for CPSES safety related buses during 345kV system faults.

LDCR-SA-2005-25, EVAL-2002-003739-1 (TJE):

Section 1A(B): In section 1A(B), under the Discussion of RG 1.75, the proposed changes will change the wording "...upstream circuit breakers..." to "...upstream circuit protective device..." in the first sentence of the second paragraph. Currently, the sentence reads as follows:

"Regulatory Position C.1 Non Class 1E power or control circuits may be isolated from their Class 1E power source by two circuit breakers, two fuses or a breaker and a fuse in series, both coordinated with an upstream circuit breaker, and the circuit breakers periodically tested. Non safety instrument circuits powered from distribution panels 1PC1, 1PC2, 1PC3, and 1PC4 will have a non safety circuit breaker or fuse connected in series with the panel circuit breaker."

The sentence will be revised to read:

"Regulatory Position C.1 Non Class 1E power or control circuits may be isolated from their Class 1E power source by two circuit breakers, two fuses or a breaker and a fuse in series, both coordinated with an upstream circuit protective device, and the circuit breakers periodically tested. Non safety instrument circuits powered from distribution panels 1PC1, 1PC2, 1PC3, and 1PC4 will have a non safety circuit breaker or fuse connected in series with the panel circuit breaker."

Note: The FSAR descriptions of, breakers and starters tripped by SIAS as an isolation device, and a single fuse as an isolation device for NSSS protection system, are being revised to include the coordination requirement with the upstream protective device. This is a clarification change to improve the readers under standing of an isolation device.

LDCR-SA-2005-25, EVAL-2002-003739-1 (TJE) (continued):

Section 8.3.1.2.1.7, part a: Currently, section 8.3.1.2.1.7 under “a. Power Circuits” reads,

"Power Circuits

The following types of devices are used in the CPSES design for isolation of power circuits:

1) Circuit breaker tripped by a safety injection signal.

2) Starter contactor opened by a safety injection signal.

3) Two circuit breakers, two fuses or a breaker and a fuse in series, both coordinated with an upstream circuit breaker, and the circuit breakers periodically tested."

The proposed changes will revise this section to read,

"Power Circuits

The following types of devices are used in the CPSES design for isolation of power circuits:

1) Circuit breaker coordinated with the upstream protective device and tripped by a safety injection signal.

2) Circuit protective device of a starter coordinated with the upstream protective device and starter contactor opened by a safety injection signal.

3) Two circuit breakers, two fuses or a breaker and a fuse in series, both coordinated with an upstream circuit protective device, and the circuit breakers periodically tested."

Note: The FSAR descriptions of, breakers and starters tripped by SIAS as an isolation device, and a single fuse as an isolation device for NSSS protection system, are being revised to include the coordination requirement with the upstream protective device. This is a clarification change to improve the readers under standing of an isolation device.

Section 8.3.1.2.1.7, part b: Currently, section 8.3.1.2.1.7 and 8.3.1.2.1.7 under “b. Control and Instrumentation Circuits” parts 5 and 6 read,

"5) Two circuit breakers, two fuses or a breaker and a fuse in series, both coordinated with an upstream circuit breaker, and the circuit breakers periodically tested, provide isolation between Class 1E and non Class 1E circuits.

6) Within the NSSS protection system cabinets, a fuse or breaker is an isolation device to prevent malfunctions in Non-Class 1E portions of a circuit from causing unacceptable influences on the Class 1E function of the circuit (Reference 48). This exception to the

LDCR-SA-2005-25, EVAL-2002-003739-1 (TJE) (continued):

isolation devices described in the preceding paragraph (5), is applicable only to the NSSS circuit design by Westinghouse. See Section 7.1.2.2.1."

The proposed changes will revise these two paragraphs to read,

"5) Two circuit breakers, two fuses or a breaker and a fuse in series, both coordinated with an upstream circuit protective devise, and the circuit breakers periodically tested, provide isolation between Class 1E and non Class 1E circuits.

6) Within the NSSS protection system cabinets, a fuse or breaker, coordinated with the upstream protective devise, is an isolation device to prevent malfunctions in Non-Class 1E portions of a circuit from causing unacceptable influences on the Class 1E function of the circuit (Reference 48). This exception to the isolation devices described in the preceding paragraph (5), is applicable only to the NSSS circuit design by Westinghouse. See Section 7.1.2.2.1."

Note: The FSAR descriptions of, breakers and starters tripped by SIAS as an isolation device, and a single fuse as an isolation device for NSSS protection system, are being revised to include the coordination requirement with the upstream protective device. This is a clarification change to improve the readers under standing of an isolation device.

LDCR-SA-2005-32, EVAL-1999-002406-2 (TJE):

Section 1A(B): 1.) In 1A(B) under the Discussion of RG 1.75 after 36th paragraph, insert the following words:

"Physical separation between non-Class 1E and Class 1E circuits or non-Class 1E and associated Class 1E circuits inside the Diesel Generator Engine Control Panels CP1/2-MEDGEE-01A/02A is not required based on the analysis provided in Section 8.3.1.4.5."

Section 8.3.1.4.5: 2.) Insert the following words after the last paragraph of sections 8.3.1.4.5:

"Separation between non-Class 1E and Class 1E circuits or non-Class 1E and associated Class 1E circuits in the Diesel Generator Engine Control Panels CP1/2-MEDGEE-01A and 02A, listed in Table 8.3-10, is not required based on the following analysis. These panels are re-classified as Multi-Train cabinets. Both the AC and DC circuits for the Diesel Generator Engine Control Panels are supplied by a Class 1E power supply. The non-Class 1E circuits in the control panels are electrically isolated by an approved design having two circuit breakers in series for electrical isolation to assure that the Class 1E power source is not adversely affected by a fault in the non-Class 1E circuit.

Internal Train Separation Exemption:

Per Regulatory Guide 1.75, non-Class 1E circuits shall be physically separated from Class 1E circuits and non-Class 1E circuits shall be physically separated from associated

LDCR-SA-2005-32, EVAL-1999-002406-2 (TJE) (continued):

Class 1E circuits by the minimum separation requirements. All cables installed in the Diesel Generator Engine Control Panels are flame retardant and meet IEEE-383 flame test requirement. Any non-Class 1E cable fault, short circuit, short to ground, or over load condition will be isolated by an isolation breaker and will not cause the cable temperature to exceed normal operating temperature. The non-Class 1E cables inside the control panel will not be degraded or will not reach the temperature that can affect the Class 1E or associated Class 1E circuits. Open non-Class 1E circuit, have no impact on Class 1E or associated Class 1E circuits. The non-Class 1E cables when maintained within their rated temperature, have no adverse impact on adjacent Class 1E or associated Class 1E cables with no physical separation because the Class 1E and associated Class 1E cables also have the same temperature ratings.

Therefore, the adequacy of the safety-related circuits to perform their safety function is maintained with no separation between non-Class 1E and Class 1E circuits or non-Class 1E and associated Class 1E circuits inside the Diesel Generator Engine Control Panels. Any faults in the non-Class 1E circuits will not compromise the safety function of the Class 1E or associated Class 1E circuits internal to the Diesel Generator Engine Control Panels. Therefore, there is no need for internal electrical separation requirements within Diesel Generator Engine Control Panels CP1/2-MEDGEE-01A and 02A."

Table 8.3-10, sheet 9: 3.) Add the next four lines at the end of TABLE 8.3-10 and before the Notes:

"CP1-MEDGEE-01A DIESEL GENERATOR 1-01 DIESEL ENGINE CONTROL PANEL -- 18

CP1-MEDGEE-02A DIESEL GENERATOR 1-02 DIESEL ENGINE CONTROL PANEL -- 18

CP2-MEDGEE-01A DIESEL GENERATOR 2-01 DIESEL ENGINE CONTROL PANEL -- 18

CP2-MEDGEE-02A DIESEL GENERATOR 2-02 DIESEL ENGINE CONTROL PANEL -- 18"

Table 8.3-10, sheet 10: 4.) Add Note "18" to end of Table 8.3-10.

"18. Equipment supplied by Delaval Engine & Compressor has been analyzed and is exempt from internal separation requirement. (Reference FSAR Section 8.3.1.4.5.)"

LDCR-SA-2006-6, EVAL-2006-000595-1 (TJE):

Section 1.6: 1.) Currently in section 1.6, the first sentence of the first paragraph reads, "Table 1.6-1 lists topical reports and other licensing documents which provide information additional to that provided in this FSAR and have been filed separately with the Nuclear Regulatory Commission (NRC) in support of the CPSES operating licenses."

LDCR-SA-2006-6, EVAL-2006-000595-1 (TJE) (continued):

Delete the words, "topical reports and other licensing" from this sentence.

The sentence will then read, "Table 1.6-1 lists documents which provide information additional to that provided in this FSAR and have been filed separately with the Nuclear Regulatory Commission (NRC) in support of the CPSES operating licenses."

2.) Currently in section 1.6, the last sentence of the first paragraph reads, "Later revisions to these documents are not part of the FSAR unless they are incorporated into this table."

Add the following words to the end of this sentence, "(except for the Technical Requirements Manual (including TRM Bases) and the Technical Specifications Bases)"

The sentence will then read, "Later revisions to these documents are not part of the FSAR unless they are incorporated into this table (except for the Technical Requirements Manual (including TRM Bases) and the Technical Specifications Bases)"

Note:

This change is consistent with Technical Specification 5.5.14 and 5.5.17 which allow changes to the TRM and TSB under 10CFR50.59. Appendix A.4.3 of NEI-98-03, "Guidelines for Updating Final Safety Analysis Reports," Revision 1, allows these type of documents to be incorporated into the FSAR by reference. NEI-98-03, Revision 1, is endorsed by NRC Regulatory Guide 1.181, "Content of the Updated Final Safety Analysis Report in Accordance with 10 CFR 50.71(e)." This is also consistent with FSAR Section 16.2. This will help eliminate confusion and allow certain changes (e.g., reformatting, consistency, and others as defined in NEI-03, Revision 1) to be excluded from 10CFR50.59 review requirements.

Table 1.6-1, sheet 2: Replace the words in the title of Table 1.6-1 from "TOPICAL REPORTS" to "DOCUMENTS" on Sheet 2.

Note:

This change is consistent with Technical Specification 5.5.14 and 5.5.17 which allow changes to the TRM and TSB under 10CFR50.59. Appendix A.4.3 of NEI-98-03, “Guidelines for Updating Final Safety Analysis Reports,” Revision 1, allows these type of documents to be incorporated into the FSAR by reference. NEI-98-03, Revision 1, is endorsed by NRC Regulatory Guide 1.181, “Content of the Updated Final Safety Analysis Report in Accordance with 10 CFR 50.71(e).” This is also consistent with FSAR Section 16.2. This will help eliminate confusion and allow certain changes (e.g., reformatting, consistency, and others as defined in NEI-03, Revision 1) to be excluded from 10CFR50.59 review requirements.

Table 1.6-1, sheet 3: 1.) Replace the words in the title of Table 1.6-1 from "TOPICAL REPORTS" to "DOCUMENTS" on Sheet 3.

LDCR-SA-2006-6, EVAL-2006-000595-1 (TJE) (continued):

2) Add the following two Reports and Reference Sections to the end of Table 1.6-1 on Sheet 3:

Technical Requirements Manual (TRM) for Comanche Peak Steam Electric Station Units 1 and 2	All Sections
Technical Specifications Bases for Comanche Peak Steam Electric Station Units 1 and 2	All Sections

Note:

This change is consistent with Technical Specification 5.5.14 and 5.5.17 which allow changes to the TRM and TSB under 10CFR50.59. Appendix A.4.3 of NEI-98-03, “Guidelines for Updating Final Safety Analysis Reports,” Revision 1, allows these type of documents to be incorporated into the FSAR by reference. NEI-98-03, Revision 1, is endorsed by NRC Regulatory Guide 1.181, “Content of the Updated Final Safety Analysis Report in Accordance with 10 CFR 50.71(e).” This is also consistent with FSAR Section 16.2. This will help eliminate confusion and allow certain changes (e.g., reformatting, consistency, and others as defined in NEI-03, Revision 1) to be excluded from 10CFR50.59 review requirements.

LDCR-SA-2006-7, EVAL-2006-000627-2 (DWS):

Section 13.3B-1: Make organizational change "Senior Vice President and Principal Nuclear Officer" to "Senior Vice President and Chief Nuclear Officer"

TMI - I.C-3: Make organizational change. Change "Vice President, Nuclear Operations" to "Site Vice President"

In 13.1.1.2.1, change "Vice President, Nuclear Operations" to "Site Vice President" wherever it appears. Change "Vice President, Nuclear Engineering" to "Vice President, Nuclear Engineering and Support" wherever it appears. Realign reporting requirements for some managers. Delete obsolete manager titles and include new titles as appropriate.

Section 13.1A: Change "Vice President, Nuclear Operations" to "Site Vice President" wherever it appears. Change "Vice President, Nuclear Engineering" to "Vice President, Nuclear Engineering and Support" wherever it appears. Delete obsolete manager titles and include new titles as appropriate. Add QA manager title and resume.

In Figure 13.1-2, change "Vice President, Nuclear Operations" to "Site Vice President" . Change "Vice President, Nuclear Engineering" to "Vice President, Nuclear Engineering and Support" wherever it appears. Realign reporting requirements for some managers. Reinstate "Plant Manager" position.

LDCR-SA-2006-7, EVAL-2006-000627-2 (DWS) (continued):

In Figure 13.1-3, change "Vice President, Nuclear Operations" to "Site Vice President" and reinstate "Plant Manager" position.

In Table 13.1-1, change "Vice President, Nuclear Operations" to "Site Vice President" and add QA Manager

LDCR-SA-2006-20, EVAL-2006-000798-2 (DWS):

Section 13.3B - Revise ORC responsibility to assess the effectiveness of the fire protection program through review of periodic audits as discussed in FSAR 17.2.18 and corrected management title.

Audits have been moved to Section 17.2.18 and are conducted by the Nuclear Overview organization.

Section 13.4 - Revised to correct wording in FSAR from NRC audits to NRC inspection reports and to reflect changes made in FSAR Section 17.2.

LDCR-SA-2004-47, EVAL-2004-001171-2 (MJR):

FSAR Table 6.2.4-1, "Containment Isolation Valving Application," footnote a) for Table item 129 is revised to clarify that valve SF-0001 associated with the Fuel Transfer Tube penetration is a non-safety related valve that has no direct containment isolation function during MODES 1 through 4. This valve is normally closed in MODES 1-4. The valve may be opened in MODES 1-4 except when the Fuel Transfer Canal is flooded to maintain the Fuel Transfer Flange as leak rate tested. Opening the valve allows for equipment testing and to support preparations for refueling operations. (This change is consistent with clarifications added to DBD-ME-013 and DBD-ME-080 per approved and implemented FDA-2004-001171-01-00.)

LDCR-SA-2003-47 (MJR):

Appendix 1A(B), Regulatory Guide 1.75, is revised to add the Unit 1 and 2 Emergency Diesel Generators to the discussion of the Partial Discharge Monitor Bus Couplers. PDM Bus Couplers were installed on EDGs per FDA-2001-001255-02. The previous reference to Unit 2 only for Component Cooling Water motor feeders is deleted to reflect that PDM Bus Couplers have now been installed on both Unit 1 and 2 Component Cooling Water motors per FDA-2000-000127.

Appendix 1A(B), Regulatory Guide 1.131, is revised to add the Unit 1 and 2 Emergency Diesel Generators to the discussion of the Partial Discharge Monitor Bus Coupler jumpers. PDM Bus Couplers were installed on EDGs per FDA-2001-001255-02.

Section 8.3.1.2.1.7, Onsite Power Systems, Compliance, RG 1.75 and IEEE-354, is revised to add the Unit 1 and 2 Emergency Diesel Generators to the discussion of the Partial Discharge Monitor Bus Coupler jumpers. PDM Bus Couplers were installed on

LDCR-SA-2003-47 (MJR) (continued):

EDGs per FDA-2001-001255-02, and specific component tag numbers and wire size details are deleted as below the level of detail required for the FSAR description. Also, the Component Cooling Water Pump Motors were added to the discussion for completeness. PDM Bus Couplers were installed on CCWP motors per FDA-2000-000127.

Section 9.2.2.2 System Description is revised to delete the previous reference to Unit 2 for the CCW pump motors to reflect that PDM Bus Couplers have now been installed on both Unit 1 and 2 Component Cooling Water pump motors per FDA-2000-000127.

Section 9.5.1.6.2, Fire Protection System, Justification for Items of Noncompliance to Appendix A to Branch Technical Position APCSB 9.5-1, Guideline D.3.f, is revised to add the Unit 1 and 2 Emergency Diesel Generators to the discussion of the Partial Discharge Monitor Bus Coupler jumpers. PDM Bus Couplers were installed on EDGs per FDA-2001-001255-02. Also, specific component tag numbers are deleted as below the level of detail required for the FSAR description.

Table 8.3-3, "Failure Mode and Effect Analysis for Auxiliary AC Power System," is revised to add items 15C, 15D, 16C, and 16D for the Partial Discharge (PD) bus couplers installed on the Emergency Diesel Generators per FDA-2001-001255-05, and to add an abbreviation note to define "partial discharge (PD)."

LDCR-SA-2004-22, EVAL-2004-002167-1 (GLM):

Revise Section 9.2.8 to be consistent with the current approved waste effluent release permit. This includes changes to reflect current terminology as well as changes to bring the FSAR Section in line with the current wastewater discharge permit.

Section 9.2.8 of the FSAR documents the Design Basis and System Description of the Waste Management System (WMS) at CPSES. The design function of the Waste Management System is the collection, retention, treatment and discharge of normally non-radioactive wastewaters. The system does this in accordance with the Texas Commission on Environmental Quality (TCEQ) and the Texas Pollutant Discharge Elimination System (TPDES) permits. The WMS collects wastewaters for processing in either the Low Volume Waste (LVW) or Co-Current Waste (COW) treatment facilities. The goal of most of the changes is to provide the description of the major components in the system and to reiterate that the release of effluents is done within the limitation of our Discharge Permit. Specifically, the wording changes involved in this submittal are administrative in nature. The regulatory agency functions of the agencies in regard to CPSES have remained the same, however, the names of the agencies have changed. The Texas Natural Resource Conservation Commission (TNRCC) is now the Texas Commission on Environmental Quality (TCEQ). The National Pollutant Discharge Elimination System (NPDES) is now the Texas Pollutant Discharge Elimination System (TPDES). While this change request was being processed, it was determined that the description of the systems should be updated to be more consistent with the wording of the current approved discharge permit and some change was necessary to outline some

LDCR-SA-2004-22, EVAL-2004-002167-1 (GLM) (continued):

current operating practices. This submittal also includes corrections in system terminology in the descriptions. The LVW facilities required more change than did the COW facility descriptions. For the most part, the facility descriptions remain unchanged although the wording has been reformatted to align better with the Discharge Permit. The changes requested better describe the use of the facilities and reinforce some detail regarding both use and operation of the facilities which fall within applicable TCEQ permit limitations.

Revise Section 9.2.8 to be consistent with the current approved waste effluent release permit. This includes changes to reflect current terminology as well as changes to bring the FSAR Section in line with the current wastewater discharge permit.

Section 9.2.8 of the FSAR documents the Design Basis and System Description of the Waste Management System (WMS) at CPSES. The design function of the Waste Management System is the collection, retention, treatment and discharge of normally non-radioactive wastewaters. The system does this in accordance with the Texas Commission on Environmental Quality (TCEQ) and the Texas Pollutant Discharge Elimination System (TPDES) permits. The WMS collects wastewaters for processing in either the Low Volume Waste (LVW) or Co-Current Waste (COW) treatment facilities. The goal of most of the changes is to provide the description of the major components in the system and to reiterate that the release of effluents is done within the limitation of our Discharge Permit. Specifically, the wording changes involved in this submittal are administrative in nature. The regulatory agency functions of the agencies in regard to CPSES have remained the same, however, the names of the agencies have changed. The Texas Natural Resource Conservation Commission (TNRCC) is now the Texas Commission on Environmental Quality (TCEQ). The National Pollutant Discharge Elimination System (NPDES) is now the Texas Pollutant Discharge Elimination System (TPDES). While this change request was being processed, it was determined that the description of the systems should be updated to be more consistent with the wording of the current approved discharge permit and some change was necessary to outline some current operating practices. This submittal also includes corrections in system terminology in the descriptions. The LVW facilities required more change than did the COW facility descriptions. For the most part, the facility descriptions remain unchanged although the wording has been reformatted to align better with the Discharge Permit. The changes requested better describe the use of the facilities and reinforce some detail regarding both use and operation of the facilities which fall within applicable TCEQ permit limitations. The second thru fifth paragraphs were deleted since they provide both duplicate information and more detail than is necessary to describe the design volumes in the settling ponds. The sixth paragraph was deleted since it is redundant to information in a new paragraph. This paragraph details periodic testing of Condensate Polishing wastes. This information is accurate but is already covered by the statements in the second paragraph which indicates that releases are controlled via the ODCM program. Typically wastes sent to the Low Volume Waste Management System do not include radioactive wastes. Although there are accident scenarios which postulate such releases, there is no normal release of such wastes to the Low Volume Waste System. Releases

LDCR-SA-2004-22, EVAL-2004-002167-1 (GLM) (continued):

are controlled via the ODCM limits as well as the limits established by the Release Permit.

Revise Section 9.2.8 to be consistent with the current approved waste effluent release permit. This includes changes to reflect current terminology as well as changes to bring the FSAR Section in line with the current wastewater discharge permit.

Section 9.2.8 of the FSAR documents the Design Basis and System Description of the Waste Management System (WMS) at CPSES. The design function of the Waste Management System is the collection, retention, treatment and discharge of normally non-radioactive wastewaters. The system does this in accordance with the Texas Commission on Environmental Quality (TCEQ) and the Texas Pollutant Discharge Elimination System (TPDES) permits. The WMS collects wastewaters for processing in either the Low Volume Waste (LVW) or Co-Current Waste (COW) treatment facilities. The goal of most of the changes is to provide the description of the major components in the system and to reiterate that the release of effluents is done within the limitation of our Discharge Permit. Specifically, the wording changes involved in this submittal are administrative in nature. The regulatory agency functions of the agencies in regard to CPSES have remained the same, however, the names of the agencies have changed. The Texas Natural Resource Conservation Commission (TNRCC) is now the Texas Commission on Environmental Quality (TCEQ). The National Pollutant Discharge Elimination System (NPDES) is now the Texas Pollutant Discharge Elimination System (TPDES). While this change request was being processed, it was determined that the description of the systems should be updated to be more consistent with the wording of the current approved discharge permit and some change was necessary to outline some current operating practices. This submittal also includes corrections in system terminology in the descriptions. The LVW facilities required more change than did the COW facility descriptions. For the most part, the facility descriptions remain unchanged although the wording has been reformatted to align better with the Discharge Permit. The changes requested better describe the use of the facilities and reinforce some detail regarding both use and operation of the facilities which fall within applicable TCEQ permit limitations. The second paragraph regarding Chemical Sump Wastes was also deleted. This paragraph indicates that Chemical Sump Wastes are being discharged to the Equalization Basin and in turn to the Natural Neutralization Basin, Neutralization Clearwell with an ultimate discharge and/or commingling with LVW Pond effluents. These elements and processing within the LVW facilities are no longer in normal practice. Currently, effluents from the Chemical Sumps are processed together with the other plant wastewaters via the Separation Surge Basin, API Oil Separator and Settling Basins. Descriptions regarding the use of the Equalization Basin lineup is no longer relevant or necessary based on the current normal operating lineups or practices.

Revise Section 9.2.8 to be consistent with the current approved waste effluent release permit. This includes changes to reflect current terminology as well as changes to bring the FSAR Section in line with the current wastewater discharge permit.

LDCR-SA-2004-22, EVAL-2004-002167-1 (GLM) (continued):

Section 9.2.8 of the FSAR documents the Design Basis and System Description of the Waste Management System (WMS) at CPSES. The design function of the Waste Management System is the collection, retention, treatment and discharge of normally non-radioactive wastewaters. The system does this in accordance with the Texas Commission on Environmental Quality (TCEQ) and the Texas Pollutant Discharge Elimination System (TPDES) permits. The WMS collects wastewaters for processing in either the Low Volume Waste (LVW) or Co-Current Waste (COW) treatment facilities. This submittal also includes corrections in system terminology in the descriptions. The LVW facilities required more change than did the COW facility descriptions. For the most part, the facility descriptions remain unchanged although the wording has been reformatted to align better with the Discharge Permit. The changes requested better describe the use of the facilities and reinforce some detail regarding both use and operation of the facilities which fall within applicable TCEQ permit limitations.

LDCR-SA-2004-44, EVAL-2001-000158-7 (GLM):

Revise Section 9.3.1 to reflect the following: 1) the word "Spare" is no longer applicable as the common compressors may be operated as the lead compressor for either unit. Therefore, spare is changed to "common", 2) each common and Unit 2 instrument air compressor has a dedicated trim cooler cooled by non-safety chilled water, 4) the Unit 1 CCW system remains in a series flow path for the unit 1 compressors. Therefore, a single trim cooler is used, 3) due to the elevated temperatures in the Turbine Building during the Summer months, a non-safety chilled water ventilation cooler is provided to duct cooled air into the compressor air inlet, ensuring intake parameters are within operational limits.

Revise Section 9.3.1 to reflect the following: Each instrument air dryer has two 100% capacity prefilters.

Revise Table 9.3-1 to reflect the following: On sheets 1 and 2, Part "A" is deleted as all 435 SCFM, rotary, two stage, oil free, water cooled air compressors have been removed from the plant.

LDCR-SA-2004-44, EVAL-2001-000158-7 (GLM) (continued):

Revise Table 9.3-1 to reflect the following: On sheet 3, revise the last 2 entries in the table to reflect that the exit cooling water temperature for the Common and Unit 2 compressors is 122 degrees F and the required cooling water flow for the Common and Unit 2 compressors is 40 gpm.

Revise Section 8.3.1.2.1 to reflect the following: The new instrument air compressor control panel CP2-CICACO-01B is Train C and some associated cables are terminated at the control panel without isolation devices.

Revise Table 8.3-10 to reflect the following: Add new instrument air compressor control panel CP2-CICACO-01B to the table.

Revise Table 8.3-11 to reflect the following: The Unit 1 power source and ID numbers are editorially corrected for instrument air compressors 1-01 and 1-02 and instrument air dryer control panel 1-02.

Revise Table 8.3-11 to reflect the following: Add CP2-CICACO-01, CP2-CICACO-02, CP2-CICYIA-01, and CP2-CICYIA-02 to the table.

LDCR-SA-2005-27, EVAL-2004-002128-4 (GLM):

Revise Section 9.2.3.1 to add description of nitrogen sparger that was installed in the Unit 1 RMWST per FDA-2004-002128-01. Adding nitrogen to the RMWST will improve the control of the dissolved oxygen concentration.

LDCR-SA-2006-8, EVAL-1999-000248-8 (GLM):

Revise Table 9.4-2 to add a note indicating that the temperatures in the DG area are maintained with the help of the DG keepwarm system.

The current design basis was established by Calculation 1-EB-302A-1 Rev. 5 "As built HVAC Calc Diesel Generator Area--Space Heat Gains, Space Heat Losses and Maximum and Minimum Temperatures - Unit 1. (dated 9/20/1989). The same design was confirmed in Unit 2 Calc. 2-HV-0009 Rev. 1. 1-EB-302-1 Rev. 5 on page 3 indicates the reason for Rev. 5 "Calculation Rev. 5 is a complete revision which takes credit for the D.G. "Keepwarm" system for space heating as per TU-Electric Letter No. OSE-89026 dated 9-4-89." The justification for this licensing basis change and the Engineering Basis for FDA-1999-000248-03 is Calculation 1-EB-302-1 Rev. 5. issued on 9/20/1989. The calculation demonstrates that the DG Jacket water 52.7 KW heater with the 27.5 KW Lube oil heater and the two installed 5 KW room heaters was more than enough heat to keep all portions of the Unit 1 DG rooms well above 40ºF. 1-EB-302-1 Rev 5 determined that the available safety margin is 56.8%. However, if we have equipment failure, or if the outside ambient temperature falls below the design basis 20ºF temperature or if we have excessive infiltration, supplemental heating and/or other compensatory measures may be required too maintain DG room temperature at or above 40ºF.

LDCR-SA-2006-19, EVAL-2004-003769-19 (GLM):

Revise Section 9.3.1.2 to delete "to regulate flow" since, although it is a function of the valves, it is not a design function of the accumulators. Discussion of the flow regulation is moved to Section 10.4.9.2 which is referenced for clarification.

Clarification suggested by SMF-2004-003769 generated in response to NRC questions. There are no changes to the design function or the method of performing the design function. See FDA-2004-003769-01 for design impact assessments and additional details.

Revise Section 10.4.9.2 to reflect the following: Add clarification to incorporate information from Section 6.2.1, SSER 17, and CPSES-200402640. This places all pertinent information in one location.

Clarification suggested by SMF-2004-003769 generated in response to NRC questions. There are no changes to the design function or the method of performing the design function. See FDA-2004-003769-01 for design impact assessments and additional details.

LDCR-SA-2006-17, EVAL-2006-000809-1 (JCH):

Table 10.4-11 entry for chlorides is incorrect. Chloride value should be "10.0" vs "1.0" mg/l (max)

This appears to be a typo. DBD-ME-212 was changed from 1.0 to 10.0 mg/l by FDA-2001-002476-01 to match existing Chemistry procedures (which had been revised to match EPRI Closed cooling Water Chemistry Guideline 1007820). The FDA failed to identify the FSAR as impacted.

LDCR-SA-2006-21, EVAL-2006-002113-1 (DWS):

Section 13.1A: Added new plant manager's resume.

FSAR Amendment 101

LDCR-SA-2005-13, EVAL-1999-003132-05 (JCH):

Section 10.4.10.5: states the following- "Each turbine side drain pot is provided with an extraction line drain valve. These valves are opened and closed manually with control-board-mounted switches. After a valve opens, it remains open until manually closed.

Revise Section 10.4.10.5 to remove extraction line turbine side drain pot level switches and their associated level indication, level control and level alarm functions. Extraction Steam system drip pots (located between the Turbine and Feedwater Heater sides of the supply line stop and check valves) are not required to provide “Level Indication and Control Functions” in order to satisfy any CPSES commitments or applicable codes and standards. This change resolves the unit difference between Unit 1 and Unit 2.

LDCR-SA-2005-30, EVAL-2003-002540-04 (JCH):

Section 10.4.2: To ensure more reliable operation of the vacuum priming pumps year-round, a modification was implemented to provide full required seal water flow rate of 3 gpm per pump from the Demineralized and Reactor Makeup Water System. The water is not cooled and recirculated but is sent to the nearby floor drain as it exits the pump.

Removal of the vacuum primary pump heat exchangers ensures that the setpoint vacuum can be produced by the vacuum priming pumps. Other clarifications were to accurately reflect the system design per FDA-2003-002540-03 and -04.

LDCR-SA-2006-26, EVAL-2004-000897-02 (GLM):

In Section 10.4.12.5.1: Revise the first and second sentence to delete reference to the pitot tube type flow meter.

FDA-2004-00897-01 changes the way the TPCW total flow is determined for Unit 2. The existing Unit 2 total flow indication is erratic and varies depending upon which pump is running. To obtain a more reliable flow indication, the East, West and recirc flows are summed then transmitted to the control room. The control room flow indication and alarms will not be changed. Unit 1 is not modified (still has the pitot tube type flow meter), this change only removes the level of detail regarding the specific type of flow meter.

LDCR-SA-2005-17, EVAL-2004-002063-7 (JDS):

Revised Table 7.5.7E, sheet 4 of 4 to incorporate commitment made during license submittal for TSTF 447 for H2 recombiner removal. This was approved by the NRC in License Amendment 117.

LDCR-SA-2005-24, EVAL-2002-001952-3 (JDS):

Revised Ch. 1A(B) to provide discussion of deviations to Regulatory Guide 1.82 that are being addressed as part of resolution of the generic issue regarding containment emergency sump performance (GSI-191).

LDCR-SA-2005-24, EVAL-2002-001952-3 (JDS) (continued):

Provide for description of the transport of debris through the radiation protection doors as a result of modifications to improve containment emergency sump performance.

LDCR-SA-2006-13, EVAL-2006-000212-02 (JDS):

Section 4.4.2.2.2 - The FSAR description of the calculation of the fuel assembly spring holddown force has been revised. The use of the mechanical design RCS flow has been replaced by the use of the best-estimate RCS flow with margin.

The current Westinghouse methods involve the use of best estimate flow (vs mechanical design flow) to calculate best estimate lift forces. An uncertainty factor (calculated by convoluting uncertainties, including an uncertainty to account for the difference of best estimate flow to design flow) is then applied resulting in the design lift forces. These design lift forces are then used to ensure the functional compliance of the holddown springs. The hold down springs remain capable of performing their function.

Section 5.1, under Best Estimate Flow and Thermal Design Flow - The FSAR description of the calculation of the fuel assembly spring holddown force has been revised. The use of the mechanical design RCS flow has been replaced by the use of the best-estimate RCS flow with margin.

The current Westinghouse methods involve the use of best estimate flow (vs mechanical design flow) to calculate best estimate lift forces. An uncertainty factor (calculated by convoluting uncertainties, including an uncertainty to account for the difference of best estimate flow to design flow) is then applied resulting in the design lift forces. These design lift forces are then used to ensure the functional compliance of the holddown springs. The hold down springs remain capable of performing their function.

LDCR-SA-2006-33, EVAL-2001-001255-17 (TJE):

Section 8.3.1.1.11.1: Replace the words "Unit 1 and Unit 2 Diesel Generators use" with the words "Each EDG uses."

Currently, this paragraph reads,

"Unit 1 and Unit 2 Diesel Generators use an upgraded digital excitation/voltage regulator. This digital exciter/voltage regulator is a Safety Related Siemens THYRIPART generator field excitation unit. This THYRIPART excitation unit utilizes a digital control system consisting of a 32-bit technology module and communications module. This system controls the output of a chopper controller circuit to achieve +0.5 percent Diesel Generator voltage regulation, and has capability of both manual as well as automatic control."

LDCR-SA-2006-33, EVAL-2001-001255-17 (TJE) (continued):

The paragraph will be revised to read,

"Each EDG uses a digital excitation/voltage regulator. This digital exciter/voltage regulator is a Safety Related Siemens THYRIPART generator field excitation unit. This THYRIPART excitation unit utilizes a digital control system consisting of a 32-bit technology module and communications module. This system controls the output of a chopper controller circuit to achieve +0.5 percent Diesel Generator voltage regulation, and has capability of both manual as well as automatic control."

Section 8.3.1.1.11.2: 1.) Add the following item to the reason for the automatic tripping of the DGs

"t. Generator underfrequency"

Delete the following paragraph

"These protective functions on the Unit 1 and the Unit 2 DG units utilize an upgraded digital multifunction protective device (MPR-1) locally which generates a common alarm to the control room."

Delete the following paragraph,

"For Unit 1 and Unit 2, the individual protective alarms except for the differential protection signal target are available locally on device MPR-1."

LDCR-SA-2006-15, EVAL-2006-001324-02 (TJE):

Section 8.3.1.1.11.3: FSAR Section 8.3.1.1.11, sub-section 3. "Testability and Maintenance," is revised to remove portions of the FSAR description of Diesel Generator (DG) periodic testing that are no longer applicable. This section of the FSAR formerly included additional detail that distinguished between DG testing performed during unit at-power operation and that which was previously restricted to performance during unit shutdowns. Surveillance tests for the DGs and the Offsite AC Sources are performed in accordance with the requirements of Technical Specifications (TS) 3.8.1 and are further described in the corresponding TS Bases. This change updates the FSAR description of DG periodic testing to be consistent with the current TS 3.8.1 surveillance mode restrictions as revised by License Amendment 124, effective April 24, 2006.

FSAR Amendment 101

LDCR-SA-2006-18, EVAL-1999-003485-02 (NSH):

Changes to Table 10.4-18, Page 1 of 1, corrects the Heater Drain Pump discharge pressure from 200 psig to 600 psig, identify temperature as 400^{O}F and identify the split of the Equalization Header as a sample point. This corrects the current FSAR Table 10.4-18, “Sample Points Pressure and Temperature Conditions” table. The Table in the FSAR currently incorrectly states that the Heater Drain Pump discharge parameters are the same as the Heater Drain Tank Equalization Header.

LDCR-SA-2006-32, EVAL-2005-001011-02 (RJK):

In FSAR table 9.3-4 the RCS Pressurizer Steam Space minimum sample rate is 0.75 GPM; in COP-101A/B (section 5.4.1) the minimum sample rate is 0.6 GPM. Based on a calculation performed, the Reynolds number for flow at 0.75 GPM is 3869. The Reynolds number for flow at 0.6 GPM is 3096. While the Reynolds number is less that the value for 0.75 GPM the number is greater that laminar flow values, therefore the minimum flow of 0.6 GPM in COP-101A/B provides flow sufficiently above laminar values to provide a representative sample.

In FSAR table 9.3-4 the SI Accumulator Tank minimum sample rate is 0.75 GPM; in COP-202A/B (section 5.1) the minimum sample rate is 1 liter/min. Based on a calculation performed, the Reynolds number for flow at 0.75 GPM is 3869. The Reynolds number for flow at 1 liter/min is 1363. A search of several references indicates that a Reynolds number of <2000 - 2300 is considered laminar flow and a Reynolds number of >4000 indicate turbulent flow. Based on the calculation, the lower flow referenced in the COP is laminar in nature. To compensate for the lower flow rate the purge volume is increased to 30 liters to ensure a representative sample of the accumulator is collected for analysis. The only item sampled for in the SI accumulator is boron, the Technical Specification limits for boron is 2300-2600 ppm, boron at the specified concentration will remain soluble well below temperatures seen in containment. Also, no particulate sampling/analysis is required from the SI accumulators. Based on recent testing on the sample system while installing new throttle valves, 1 liter/min is the maximum flow rate that can be expected through the lines as constructed.

LDCR-SA-2006-5, EVAL-2002-004206-04 (RJK):

In FSAR Section 3.6B.2.5.2 the Unit 2 system design pressure has been established at 1860 psig to bound the maximum SI pump discharge pressure that could exist following a LOCA and while in the recirculation mode. The system piping and components have been re-evaluated for this higher design pressure. In Table 6.3-2 the relief valve set points have been changed to 1860 psig, i.e., just above the maximum postulated SI pump discharge pressure, to prevent their opening while in the recirculation mode. Increasing the relief valve set points from 1750 psig to 1860 reduces the probability that the valves will open while the SI system is operating in the recirculation mode and, therefore, provides greater assurance that they can perform their function as a boundary for a closed system outside containment.

LDCR-SA-2006-5, EVAL-2002-004206-04 (RJK) (continued):

The Unit 2 system design pressure has been established at 1860 psig to bound the maximum SI pump discharge pressure that could exist following a LOCA and while in the recirculation mode. The system piping and components have been re-evaluated for this higher design pressure.

In Table 6.3-1 the Unit 2 relief valve set points have been changed to 1860 psig, i.e., just above the maximum postulated SI pump discharge pressure, to prevent their opening while in the recirculation mode. Increasing the relief valve set points from 1750 psig to 1860 reduces the probability that the valves will open while the SI system is operating in the recirculation mode and, therefore, provides greater assurance that they can perform their function as a boundary for a closed system outside containment.

LDCR-SA-2005-26, EVAL-2005-002515-02 (JDS):

Revised sections 4.2, 4.3.2, 4.4.1, Appendix 4A Tables 4A.1.2-1, 4A.2.2-2, and 1.6-1: The Unit 1 Cycle 12 reload core design consists of 88 Westinghouse IFM/OFA fresh fuel assemblies, 89 Westinghouse Revised P+ once-burned fuel assemblies from U1C11(including one reconstituted with 3 stainless steel rods) and 16 twice-burned Westinghouse Revised P+ assemblies from U1C11. The Westinghouse Revised P+ design includes a small hole, debris-filtering bottom nozzle design, longer solid end plugs on the fuel rods, and an alternate "P-grid" located just above the bottom nozzle to trap any debris making it through the bottom nozzle. In addition to the above features, the U1C12 fresh IFM/OFA fuel assemblies include IFM grids for enhanced fuel performance and an oxide coating at the bottom 7 inches of each fuel rod for fuel rod protection. Oxide forms naturally on the fuel cladding during normal operation so this coating has no impact on fuel design function. The pressure drop through the Westinghouse Revised P+ assemblies is slightly lower than that through the co-resident fresh Westinghouse IFM/ OFA assemblies while the heat transfer characteristics are improved by the IFMs. The effects of the mixed core on the thermal-hydraulic response are considered. The impact of the stainless steel, unheated rods in the reconstituted assembly on the mechanical, nuclear and thermal-hydraulic designs was also considered.

Added COLR references from Section 5.6.5 of the Technical Specifications for completeness.

Added Zirlo reference for the specific cladding used by Westinghouse fuel.

Added discussion on ZIROL fuel, reconstitutided fuel, and Westinghouse Optimized fuel with axial blankets or integral fuel burnable absorber. These fuel types and options are loaded into Unit 1 Cycle 12.

Added fuel cladding discussions on fretting, cycling and fatigue, and irradiation stability of the cladding and reference.

Added Zirlo reference for the specific cladding used by Westinghouse fuel.

LDCR-SA-2005-26, EVAL-2005-002515-02 (JDS) (continued):

Added FRA-ANP (framatome) to cover both fuel vendors used.

Added references for to Westinghouse topicals (WCAPs) used to support Unit 1 cycle 12.

Add discussion for reconstituted fuel used in Unit 1 cycle 12.

LDCR-SA-2006-27, EVAL-2006-002148-02 (JCH):

Replace "Engineering Programs Manager" with "Technical Support Manager in paragrahs 13.3B.1.2 and 13.3B.1.4.

Move item 2 under paragraph 13.3B.1.4 to item 3 under paragraph 13.3B.1.2 and renumber subsequent items under 13.3B.1.2 and 13.3B.1.4.

Reassignment of responsibilities is due to reorganization as a result of business process outsourcing.

LDCR-SA-2006-29, EVAL-2001-002001-01 (DWS):

Table 17A-1: Allow permanent installation and erection of Scaffold poles inside Containment Steam Generators Compartments or Loop Rooms and permit storage racks for scaffold material outside the loop rooms at the lower elevation. Reference FDA 2006-002001-01.

LDCR-SA-2006-28, EVAL-2006-001288-03 (JDS):

Update of FSAR for the Unit 2 Cycle 10 core configuration and operation. This update replaces the current FSAR Section 4B in its entirety.

Add reference to section 9.1.4.2.1 for a description of the soluble boron credit.

Add additional description for the soluble boron credit. 9.1.4.2.1 describes the soluble boron credit

Add Step 5 for conservative actions to be performed for operator actions to be performed for primary to secondary break.

LDCR-SA-2007-1, EVAL-2006-002939-02 (DWS):

Section 13.4-1: Change organizational name from "Nuclear Overview" to "Quality Assurance".

Section 14.2.2.4.6 Change title from "Director of Nuclear Overview" to "Director, Oversight & Regulatory Affairs". Section 14.2.2.6 & 14.2.2.8 change organizational name from "Nuclear Overview" to Quality Assurance".

LDCR-SA-2007-1, EVAL-2006-002939-02 (DWS) (continued):

Section 1.B.1.2 CPSES Response - change organizational name from "Nuclear Overview" to "Quality Assurance".

Section 1.C.5 change organizational name from "Nuclear Overview Department" to "Performance Improvement Department" in three places.

Section 17.2: TOC Change title from "Director Nuclear Overview" to Director, Oversight & Regulatory Affairs"

Section 17.2.1.1.2 Add additional responsibility for to the Site Vice President. Responsible for "Technical and administrative direction of the Director, Performance Improvement."

Section 17.2.1.1.3 Add responsibility for Plant Manager. Responsible for Tecnical and administrative direction to the Director, Plant Support.

Section 17.2.1.1.4 Change title from "Director Nuclear Overview" to Director, Oversight & Regulatory Affairs", change organizational name from "Nuclear Overview" to "Quality Assurance", and revise duties and responsibilities for the Director Nuclear Oversight & Regulatory Affairs and add duties and responsibilities for the Quality Assurance Manager.

Section 17.2.1.2 Change title from "Director Nuclear Overview" to Director, Oversight & Regulatory Affairs", change organizational name from "Nuclear Overview" to "Quality Assurance", and remove function number 10 "Administering and facilitating the corrective action program."

Section 17.2.1.5.1 Change title from "Director Nuclear Overview" to Director, Oversight & Regulatory Affairs."

Section 17.2.2 Change title from "Director Nuclear Overview" to Director, Oversight & Regulatory Affairs", change organizational name from "Nuclear Overview" to "Quality Assurance", add duties for the Quality Assurance Manager, remove evaluations and replace with "surveillance and audits", and remove the responsibility for "Administering and facilitating the corrective action program."

Section 17.2.5 Change organizational name from "Nuclear Overview" to "Quality Assurance", remove evaluations and replace with "surveillance and audits"

Section 17.2.6.1 Change title from "Director Nuclear Overview" to "Quality Assurance Manager", change organizational name from "Nuclear Overview" to "Quality Assurance"

Section 17.2.7 Change organizational name from "Nuclear Overview" to "Quality Assurance"

Section 17.2.9 Change "procedures shall be reviewed by the Nuclear Overview Department or designee" to "review by Quality Assurance or other qualified personnel."

LDCR-SA-2007-1, EVAL-2006-002939-02 (DWS) (continued):

Section 17.2.10 Change title from "Director Nuclear Overview" to "Quality Assurance Manager", change organizational name from "Nuclear Overview" to "Quality Assurance"

Section 17.2.12 Change organizational name from "Nuclear Overview" to "Quality Assurance" and add "TXU Power" in front of manager of the oraganization responsible for the calibration.

Section 17.2.14 & 17.2.15 Change organizational name from “Nuclear Overview” to “Quality Assurance”.

Section 17.2.16 Add "The Director, Performance Improvement is responsible for administrating and faciltating the corrective action program".

Section 17.2.18 & .1 & .2 & .2.1 Replace "evaluation" with audit, change title from "Director Nuclear Overview" to "Quality Assurance Manager", and change organizational name from "Nuclear Overview" to "Quality Assurance"

Section 13.1: TOC Change title from "Director Nuclear Overview" to Director, Oversight & Regulatory Affairs", Change organizational name from "Nuclear Overview" to "Quality Assurance".

Section 13.1 Change organizational name from "Nuclear Engineering to Nuclear Engineering & Support; Regulatory Affairs to Oversight & Regulatory Affairs; Nuclear Overview to Quality Assurance.

Section 13.1.1.2.1 added "Senior" to title of "Vice President & Chief Nuclear Officer" and added position of "Director, Performance Improvement" with responsiblities outlined. Add "Supply Chain and Procurement to Director, Plant Support responsibilities. Removed position of "Emergency Planning Manager"

Section 13.1.1.2.2 Revise organization name to Nuclear Engineering & Support. Removed position of "Manager, Administrative Services" and moved responsibility to Manager, Project Engineering.

Section 13.1.1.2.3 Change title from "Director Nuclear Overview" to Director, Oversight & Regulatory Affairs" and revise organizational name.

Section 13.1.1.2.4 Change organizational name from "Nuclear Overview" to "Quality Assurance", Change title from "Director Nuclear Overview" to Director, Oversight & Regulatory Affairs", remove responsibilities for "Providing for the review and assessment of reports of nuclear industry operating experience.", "Administering and facilitating the corrective action program.", and "Provide for the trending and analysis of conditions adverse to quality." The responsibilities are now under the Director, Performance Improvenment who reports to the Site Vice President.

Section 13.1.2.1.2 Rewrite responsibilities of "Shift Operation Manager"

FSAR Amendment 101

LDCR-SA-2007-1, EVAL-2006-002939-02 (DWS) (continued):

Section 13.1.2.1.3 Revise organizational manager titles.

Section 13.1.2.1.4 Editorial changes

Section 13.1.2.1.5 Remove the organization "Central Organization for Reliable Plant Systems (CORPS). This organization has been reassigned and renamed.

Section 13.1.2.1.6 Delete section number (number only).

Table 13.1: Revise titles, remove PLANT MOD TEAM MANAGER and insert Project Engineering Manager, Change title from "Director Nuclear Overview" to Director, Oversight & Regulatory Affairs".

Section 13.1A-1: Insert resumes and titles for new personnel and change title from "Director Nuclear Overview" to Director, Oversight & Regulatory Affairs". Remove old titles and resumes.

Section 13.3 Delete redundant and historical information on Fire Protection.

Section 13.3B Editorial changes to Fire Protection discription.

Section 13.3B.1.2 & .1.3 & .1.4 & .1.5 Revise management titles

Section 13.4-1: Change organizational name from "Nuclear Overview" to "Quality Assurance"

Sections 13.5-1, 5, 7: Correct name of company from TXU Energy to TXU Power and revise management titles.

Figure 13.1-2: Added Director, Performance Improvement and re-alignment of reporting respondibilities of the Corrective Action Program Manager and the Quality Assurance Manager.

Figure 13.1-3: Added Director, Performance Improvement and change various management titles.

LDCR-SA-2004-42, EVAL-2004-000773-01 (JCH):

Revised sections 3.5.1, 5.4.1, 7.1.2, 7.3.2, 7.7.2, 9.5.1, 10.2.2, 10.2.3, 10.2.4 and Table 7.3-4: The requirement for a complete maintenance inspection of the mechanical overspeed protection system every refueling outage has been removed, based on the fact that the mechanical overspeed system has been removed and replaced with a digital electronic protection system. The new digital overspeed protection system is auotmatically tested periodically during each shift and is verified operational every 2 weeks. The turbine trip block is also tested every 2 weeks

LDCR-SA-2004-42, EVAL-2004-000773-01 (JCH) (continued):

Deleted mechanical overspeed trip since the device is removed and added words to describe the new electronic overspeed systems

Revised "3. Turbine" of this section. This section lists equipment that cannot be tested at full power so as not to damage equipment or upset plant operation. The turbine trip solenoids were tested at power every 2 weeks under OPT-217, "Protective devices test". Under the new system, the turbine trip block trip solenoid valves are testable online and will also be tested every 14 days. The Turbine Trip Block will be tested during each startup from refueling outage.

Inserted language to indicate that the slave-relay test results may be observed by the Operator on the OM screen

Remove the statement "A load demand greater than full power is prohibited by the turbine control load limit devices."

There were two such considered ‘load limiting devices.’ One was built into the original EHC control system. The operator could set this to limit the adjusted setpoint. This feature presented certain control problems that resulted in operator confusion and therefore not used. This feature was deleted when the TXP EHC control system was installed because there was no added value.

The second load limiting device is built into the mechanical hydraulic controller. The load limiting portion of the startup and load limiting device mechanically limited the hydraulic governor output which limited the hydraulic output of the electrohydraulic converter. This feature could limit speed since it acting on the hydraulic speed controller but could only limit megawatt output by limiting the amount the control valves could open due to the hydraulic limitation. This feature could not be effectively used to limit full output power because there is no accurate way to set it to perform this function and not interfere with the EHC control system.

The MHC is removed, and therefore, no longer available for this function. In reality, the MHC could never perform this function.

The only limitation to load is the normal load setpoint set by the operator on the operator control screen.

The following component are being removed and replaced by the new system:

- Mechanical Hydraulic Controller (MHC): The new system has enough built-in redundancy and diversity to protect the turbine against an overspeed event.The MHC is no longer needed with the new EHC control system which incorporates a new EH converter design.

Added fire test standard IEC60332-3.

LDCR-SA-2004-42, EVAL-2004-000773-01 (JCH) (continued):

Various pages in Section 10.2

The mechanical turbine trip devices are being deleted and replaced with a fully electronic trip system. The existing electronic turbine protection systems are being upgraded to a modern digital fail-safe system. Changes to the FSAR are necessary to remove references to deleted equipment as well as add section to describe the new system.

The new turbine protection system consists of a redundant automation system with redundant CPUs and a triple redundant fail-safe turbine trip system. The interface between the turbine trip system and the turbine hydraulics is performed by a redundant hydraulic trip block containing 3 trip solenoids. The turbine trip is performed with 2 of 3 trip logic resulting in rapid de-pressurization of the turbine trip fluid. The loss of trip fluid causes all stop and control valves to rapidly close isolating steam from the main turbine.

All of the analog trip signals are connected to the automation system. The redundant input signals are independent from each other by connecting them to different input/ output modules with separate power supplies. The software with the applicable logic (2 of 2, or 2 of 3) is running on the redundant CPUs of the automation system. The automation system provides 3 redundant binary outputs (trip) signals to the fail-safe turbine trip system.

Binary inputs from field devices are directly connected to the fail-safe turbine trip system. Each binary input is connected to each channel of the turbine trip system. The output of each channel of the turbine trip system is connected to each normally energized trip solenoid (3 each) of the hydraulic trip block.

The turbine trip block is the interface between the turbine trip system and the turbine hydraulic system. The three trip solenoids of the trip block are normally energized by the turbine trip system. If any two trip solenoids valves are de-energized, the turbine will trip. This fail safe arrangement provides high degree of availability, reliability and protection of the turbine generator system.

The actual position of the trip piston in each individual channel of the trip block is measured by a position transducer. The position signals are used for status indication and feedback signals.

With the exception of the hydraulic trip devices, the new Automatic Turbine Tester (ATT) performs the same functions as the old ATT, however, the new design is implemented in software rather than hardware. The new ATT Trip Block test will be an operator initiated test.

LDCR-SA-2004-42, EVAL-2004-000773-01 (JCH) (continued):

Specific Changes

The following components are being removed and replaced by the new system:

a) Mechanical Hydraulic Controller (MHC): The new system has enough built-in redundancy and diversity to protect the turbine against an overspeed event.The MHC is no longer needed with the new EHC control system which incorporates a new EH converter design.

b) Load-limiting device: The load limiting device existed but was never used in the old system. Under the old system, the load limit was set at the maximum allowable, 1500 MWe, so that it wouldn't interfere with slight fluctuations that occurred during normal turbine operation. The new system does not have a load limit device. The MHC also had a so called load limiting device also. This was also no used for the same reason. The reference to load limit devices is being removed from the FSAR.

d) Extended Turbine Protection, which housed the automatic vibration trips and electrical low vacuum system. The electrical low vacuum system is incorporated into the new Turbine Protection system, where two out of three trip logic is performed in the software. The vibration trips will no longer be automatic, based on the following:

1) There is no code, standard, or regulatory requirement for these vibration trips.

2) The trips are not required by the plant insurer.

3) Operating experience with large turbine generators (fossil and nuclear) indicates that half of the turbine trips due to this system are spurious, and a vast majority of the remaining trips are also covered by other tripping events.

4) Several large turbine generator manufacturers (including Westinghouse) do not ship their equipment with this trip installed.

5) The high vibration alarm on the control board is retained, which will annunciate whenever any vibration is high to alert the operator. The operator will take the necessary action including turbine trip, if required to protect the turbine.

LDCR-SA-2005-16, EVAL-2004-001338-02 (JCH):

Revise section 3.9B: Delete the following: "After completion of testing , snubbers are disassembled and examined."

Snubbers are not disassembled after being tested, they are installed back in their locations unless they fail. If a snubber fails, then it may be disassembled to determine the cause of the failure.This is consistent with the ASME OM Code 1998 Edition through 2000 addenda and STA-742, "Snubber Surveillance Program."

FSAR Amendment 101, Supplement a

LDCR-SA-2006-2, EVAL-2004-001966-02 (TJE):

Justification: The new Seismic Monitoring System with only free-field ground motion input will not compromise the ability of the system to determine whether or not the OBE was exceeded and subsequent shutdown of both units per Appendix A of 10CFR100. Therefore, the new Seismic Monitoring System does not present any added risk to public health or nuclear safety.

Replace the discussion of RG 1.12 in 1A(B) that says,

"The installation of instrumentation for earthquakes in the CPSES plant is in conformance with the requirements of Revision 1 (4/74) of this regulatory guide."

with the words,

"The installation of instrumentation for earthquakes in the CPSES plant meets the intent of Revision 1 (4/74) of this regulatory guide with respect to the ability to determining exceedance of the OBE in a timely manner. Seismic instrumentation includes only the free-field triaxial accelerometer installed in the Yard. Determination of OBE exceedance will be based on the methods of ANSI/ANS-2.10-2003, "Criteria for the Handling and Initial Evaluation of Records from Nuclear Power Plant Seismic Instrumentation." "

1.) Delete all of section 3.7B.4.1 and insert the following:

"The seismic monitoring system meets the intent of RG 1.12, Rev. 1, with respect to the ability to determining exceedance of the OBE in a timely manner. Seismic instrumentation includes only the free-field triaxial accelerometer installed in the Yard. For the purpose of determining whether or not the OBE has been exceeded, ANSI/ANS-2.10-2003, "Criteria for the Handling and Initial Evaluation of Records from Nuclear Power Plant Seismic Instrumentation," uses the free-field accelerometer data as input to address 10CFR100 Appendix A requirements in paragraph (V)(a)(2). Exceedance above the OBE ground motion level will require structural response analyses to be performed (ANSI/ANS-2.23-2002, "Nuclear Power Plant Response to an Earthquake"). The seismic monitoring system used to record a seismic event is in accordance with the requirements described in ANSI/ANS-2.2-2002, "Earthquake Instrumentation Criteria for Nuclear Power Plants." The seismic monitoring system has the following components:

1. A triaxial accelerometer located in the free-field. The function of the triaxial accelerometer is to provide the acceleration time-history responses where the affects associated with surface features, buildings, and components will be insignificant.

2. A digital recorder that continuously monitors the free-field accelerometers with a solid state archival system. The function of the recorder is to provide a recording of the seismic event for post-event evaluation. The recorder will capture the 3-seconds preceding the exceedance of the seismic trigger threshold, and will continue to record data for a minimum of 5-seconds beyond the last recorded exceedance of the seismic trigger threshold.

LDCR-SA-2006-2, EVAL-2004-001966-02 (TJE) (continued):

3. A controller that will evaluate the recorded data in a timely manner. The function of the controller is to determine whether the OBE has been exceeded.

4. An uninterrupted power supply battery backup. The function of the battery backup is to ensure a minimum of 25-minutes of recorded data will be collected.

5. The free-field accelerometers will also function as the seismic switch. The recorder will continuously monitor the free-field accelerometers. The seismic trigger is a threshold ground acceleration value designed to initiate the event recording process at a value significantly below that of the OBE.

A schematic diagram of the seismic monitoring system is presented on Figure 3.7B-54. The free-field triaxial accelerometer described previously is provided for CPSES Unit 1 as allowed by Section 4.5 of ANSI/ANS-2.2-2002. The seismic monitoring system conforms to the requirements of ANSI/ANS-2.2-2002, as described above, including calibration and channel checks."

2.) Delete all of section 3.7B.4.2 and insert the following words,

"The recorder, controller, computer screen display, printer, and uninterruptible power system are located in an instrument rack in the Control Room. In case of any seismic activity of sufficient intensity to activate the seismic monitoring system, the Control Room operator is alerted by means of the seismic annunciation system, which consists of visual and audible alarms. The first notification will be that an event is in progress by the exceedance of the seismic trigger threshold and activation of the recorder. The second notification will be provided by the controller to indicate that the OBE has been exceeded and that shut down is required. A redundant set of notification indications is provided on the front of the seismic monitoring system in the form of light-emitting diodes (LEDs).

Delete all of section 3.7B.4.3 and insert the following words:

"This equipment computes and displays the free-field response spectra automatically on the computer screen following the event and prints a hardcopy on the system's printer. No Operator action is required to compute and print the response spectra. The seismic monitoring instrumentation facilitates the Operators ability to rapidly determine whether or not the OBE has been exceeded. In the event that the system fails to provide annunciation to one or both Control Rooms, local LED indication is provided on the face of the controller. The Control Room Staff will be alerted to the seismic event through perception of the building motions and external news sources. In addition, the control room operator is provided various screen displays that present the results of the analysis of the ground motion data. Therefore, failure to fully annunciate will not prevent the Control Room Staff from being alerted to the situation. The operator is required to request maintenance and engineering support to evaluate the validity of any alarm or indication of a seismic event. In response to a seismic event, the operator is required to perform focused walkdowns to assess plant damage and the availability of safe shutdown

LDCR-SA-2006-2, EVAL-2004-001966-02 (TJE) (continued):

equipment. The operator is required to shutdown both units if the Seismic Monitoring System determines that the OBE has been exceeded. In the event that the System is not available or functioning, the operator is required to request engineering to determine whether or not the OBE was exceeded."

Delete all of section 3.7B.4.4 and insert the following words,

"Recorded actual time histories from a significant seismic event that has occurred at the site are used to determine whether the OBE has been exceeded. The acceleration response spectrum from the actual time histories will be compared to the design spectra in the FSAR Figures 3.7B-1 and 3.7B-6. Due to large conservatism in the generation of in-structure responses, a detailed comparison of measured to predicted responses is not required."

This figure will be revised to reflect the new seismic instrumentation schematic diagram. See EVAL-2004-001966-01 for the markup.

LDCR-SA-2007-4, EVAL-2006-003263-04 (TJE):

Delete the "F" in front of the word "DISCUSSION" from the last entry in the Table of Contents

1A(B) FDISCUSSION OF REGULATORY GUIDES

In 1A(B), under the discussion of exceptions to compliance with RG 1.137:

1.) add "[49]" after "ANSI N195-1876" in item 1

2.) in item 4.a, add a "*" before and "when tested in accordance with ASTM D1298-1980" after the words "API or Specific Gravity"

3.) in item 4.d, remove the sapce between "D4176-" and "1982" and replace "ASTM-D1796-1968" with "ASTM D1796-1986"

4.) In the paragraph after item 4.d, near the end of the sentence, replace the "or" with "," and add ", or ASTM D4294-2003" at the end of the sentence.

5.) Add the following note after the paragraph that follows section 4.d,

"*If new fuel oil does not meet the diesel generator manufacturer’s requirements for absolute specific gravity at 60/60°F of "greater than or equal to" 0.8348 or for API gravity at 60°F of "less than or equal to" 38°, it is acceptable to add new fuel oil to the storage tank(s) only if, after being added, the entire storage tank(s) will meet the manufacturer’s recommendations."

LDCR-SA-2007-4, EVAL-2006-003263-04 (TJE) (continued):

At the end of the discussion of exceptions to RG 1.137, add exception 9:

"9. C.2.a

If new fuel oil does not meet the diesel generator manufacturer's requirements for absolute specific gravity at 60/60°F of "greater than or equal to" 0.8348 or for API gravity at 60°F of "less that or equal to" 38°, it is acceptable to add new fuel oil to the storage tank(s) only if, after being added, the entire storage tank(s) will meet the manufacturer's recommendations."

At the end of the Reference secion in 9.5, add reference number 49,

"49. ANSI N195-1976, 'Fuel Oil Systems for Standby Diesel Generators'"

In the paragraph before section 9.5.4.2.2, add the following paragraph,

"If new fuel oil does not meet the diesel generator manufacturer's requirements for absolute specific gravity at 60/60°F of "greater than or equal to" 0.8348 or for API gravity at 60°F of "less than or equal to" 38°, it is acceptable to add new fuel oil to the storage tank(s) only if, after being added, the entire storage tank(s) will meet the manufacturer's recommendations."

Before section 9.5.4.2.2.6, add the following paragraph,

"If new fuel oil does not meet the diesel generator manufacturer's requirements for absolute specific gravity at 60/60°F of "greater than or equal to" 0.8348 or for API gravity at 60°F of "less than or equal to" 38°, it is acceptable to add new fuel oil to the storage tank(s) only if, after being added, the entire storage tank(s) will meet the manufacturer's recommendations."

After the second paragraph of section 9.5.4.4, add the following paragraph,

"If new fuel oil does not meet the diesel generator manufacturer's requirements for absolute specific gravity at 60/60°F of "greater than or equal to" 0.8348 or for API gravity at 60°F of "less than or equal to" 38°, it is acceptable to add new fuel oil to the storage tank(s) only if, after being added, the entire storage tank(s) will meet the manufacturer's recommendations."

LDCR-SA-2007-3, EVAL-2002-000162-06 (GLM):

Revise section 9.3.4.1.1.1 to indicate that if the BTRS chiller and associated components are used in the future that the flow and piping vibration response will be verified prior to use.

This change clarifies the description of the BTRS to add the commitment for testing the BTRS chiller and associated components. Since load follow ops are not used at CPSES,

LDCR-SA-2007-3, EVAL-2002-000162-06 (GLM) (continued):

there are no current plans to ever use these components. The addition of this commitment to perform testing prior to use in section 9.3.4.1.1.1 ensures that this testing will be incorporated into operating procedures if this part of the system is ever used in the future.

LDCR-SA-2006-4, EVAL-2005-000657-01 (RJK):

This change reflects construction of a long-term storage facility (OSGSF) for the long-term storage of four Unit-1 Old Steam Generators, one Unit -1 Old Reactor Vessel Storage head and one Unit-2 Old Reactor Vessel Head. The design function of the OSGSF is to limit the on-site and off-site radiation exposure from the old SGs and old RVHs and any attached components that are stored inside the OSGSF. The OSGSF provides sufficient shielding to meet the external dose limits specified in 10CFR20 and 40CFR190. Any postulated failure of the OSGs and ORVHs/CRDMs, due to the collapse of the OSGSF due to seismic event or any other natural phenomenon, or due to the impact of the components with the ground when they are dropped, will not result in an off-site dose greater than 0.5 rem to the whole body or its equivalent to any part of the body in accordance with the 10CFR20 and 40CFR190.

This change reflects construction of a long-term storage facility (OSGSF) for the long-term storage of four Unit-1 Old Steam Generators, one Unit -1 Old Reactor Vessel Storage head and one Unit-2 Old Reactor Vessel Head. This change extends the area shown on the site plot to now include that new facility.

LDCR-SA-2005-12, EVAL-2005-001957-02 (CBC):

FSAR Sections 1, 6 and 15 are revised to reflect new methods an assumptions for evaluating radiological consequences for design basis accidents which are adopted consistent with NRC Regulatory Guide 1.195 and the new Control Room Habitablity Program / Control Room Integrity Program. These methods and assumptions were approved by the NRC in License Amendment 130. See TXX-06151 and TXX-06193 for additional information.

LDCR-SA-2007-12, EVAL-2004-002120-12 (TJE):

LDCR SA-2007-012 removes any ambiguity from the FSAR that the spare Startup Transformer XST1/2 can be energizied promptly, via a motor operated switch, is available to back up XST2.

1.) In the first full paragraph on page 8.2-2, replace the word "The" with "A" such that the sentence reads:

"A spare startup transformer, XST1/2 with dual primary windings (345-kV and 138-kV), is stored in a dedicated location under the 345-kV line to XST2 (refer to Figure 8.2-1)."

LDCR-SA-2007-12, EVAL-2004-002120-12 (TJE) (continued):

2.) In the next sentence of the same paragraph, replace the words "can be used" to the words "must be physically relocated", such that the sentence reads,

"This transformer must be physically relocated to replace XST2 or XST1 if required."

LDCR-SA-2006-42, EVAL-2003-002426-21 (GLM):

Revise Figure 1.2-1 to show deletion of the RCA Yard Entrance Radiation Protection Building.

The RCA Yard Entrance Radiation Protection Building was removed during the Unit 1 Steam Generator Replacement Project. The building has no radiation protection functions and only functions as storage and an access point into the Unit 1 yard area.

Add "Item 8" to Section 3.8.1.1.6 which is titled "Containment Alternate Access for the Steam Generator and Reactor Pressure Vessel Head Replacement (Unit 1)." Item 8 details the codes and specification used for the Unit 1 RSG Containment Alternate Access (CAA) restoration.

Add reference to structural welding code AWS D1.4-1998 in Section 3.8.1.2.4.

This code was used for the Unit 1 Containment Alternate Access during the Steam Generator Replacement Project.

Section 3.8.1.6.2, Item 1, add reference to ASTM A706 for Unit 1. Section 3.8.1.6.2, Item 3, add references to codes and standards used in support of the Unit 1 Steam Generator Replacement Project.

These codes and standards were used in support of the Unit 1 Steam Generator Replacement Project.

Clarification to sections 3.8.1.6.3 and 3.8.1.6.4 related to codes and standards used in support of the Unit 1 Steam Generator Replacement Project.

These codes and standards were used in support of the Unit 1 Steam Generator Replacement Project.

LDCR-SA-2006-40, EVAL-2003-002426-20 (RJK):

Update reference power in Section 1.2.2 for Unit 1 to 3458 MWt to reflect uprate that was implemented in 1RF09.

Justification: this 1.4% power uprate previously occurred during 1RF09 as implementation of License Amendment 89..

Adds five new references to Section 1.6 to reflect RSGs.

LDCR-SA-2006-40, EVAL-2003-002426-20 (RJK) (continued):

Adds new code reference in Section 1A(N) for Unit 1 RSGs (ANSI N45.2.2-1978) in RG 1.38 discussion.

Updates material descriptions in RG 1.43 discussion of Section 1A(N) to reflect RSGs and new RX head.

Adds new code reference in Section 1A(N) for Unit 1 RSGs (ANSI/ASME NQA-1) in RG 1.64 discussion.

Updates Table 1A(N)-1 to reflect Unit 2 only for RG 1.66 applicability.

Updates accident analysis discussions in 3.6B to specify new analyses for Unit 1 RSGs.

Updates text references in 3.6B to identify separate Tables for Unit 1 and Unit 2 parameters.

Adds 8 new references to Section 3.6B to reflect RSGs.

Split Table 3.6B-4 into separate Tables (4A and 4B), one for each unit.

Added NOTE that Table 3.6B-6 is for original SGs only and that Unit 1 RSGs had separate mass and energy release data calculated with RELAP5/MOD3.

Specified that discussion of critical damping values in Section 3.7N.1.3 are for Unit 2 only. Unit 1 is now discussed in Section 3.9N.1.4.3.

add the following statement to Sections 3.8.4.3.2 and 3.8.4.3.3:

"See Section 3.6B.1.2.3 "Structural Design Margins" for additional requirements in the MS/FW penetration areas inside the Safeguards Building."

Update Section 3.9N listing of Computer Programs Used in Analyses to reflect RSG models.

Update Section 3.9N discussion of seismic design considerations in Sections 3.9N.1.4.2, 3.9N.1.4.3, 3.9N.1.4.4, and 3.9N.2.5 to reflect RSGs.

Add eight new references to reflect RSG models to Section 3.9N.

Add the following NOTE to Figure 3.9N-1:

"FOR UNIT 1, THE REPLACEMENT STEAM GENERATOR ACTUALLY HAS 8 MASSES DISTRIBUTED ALONG THE VERTICAL CENTERLINE, AND THE SNUBBERS HAVE BEEN ELIMINATED FROM THE UPPER SUPPORT"

Split Table 3.9N-14 into separate Tables (14A and 14B), one for each unit.

LDCR-SA-2006-40, EVAL-2003-002426-20 (RJK) (continued):

Split Table 3.9N-15 into separate Tables (15A and 15B), one for each unit.

Split Table 3.9N-16 into separate Tables (16A and 16B), one for each unit.

Split Table 3.9N-21 into separate Tables (21A and 21B), one for each unit.

Split Figure 4.4-21 into separate Figures (21A and 21B), one for each unit.

Split Table 5.1-1 into separate Tables (1A and 1B), one for each unit.

Added applicable code cases used for manufacture of RSGs; N-20-4, 2124-1, and 2143-1 to Section 5.2.

Updated Table 5.2-1 to reflect new code addenda for Unit 1 RSGs and RX head.

Updated Table 5.2-2 to reflect new RCS pressure boundary materials for Unit 1 RSGs and RX head.

Split Table 5.2-6 into separate Tables (6A and 6B), one for each unit.

Updated Table 5.2-7 to reflect applicable code cases used for manufacture of RSGs; N-20-4, 2124-1, and 2143-1.

Replace the data in the first 8 lines of Table 5.3-16A to reflect the Fracture Toughness Test report numbers for the RSGs.

Add weld metal fracture toughness data for Unit 1 Replacement Steam Generator in Table 5.3-17A.

Add new section 5.4.2A to discuss Unit 1 RSG materials. Renumber existing Section 5.4.2 to 5.4.2B and make it Unit 2 specific.

Update hotlinks throughout section to either 5.4.2A or 5.4.2B as appropriate.

Update references in Section 5.4.2 to reflect Unit 1 RSGs.

Update SG design data in Table 5.4-3 to reflect Unit differences between Unit 2 original SGs and Unit 1 RSGs.

Split Table 5.4-4 into separate Tables (4A and 4B), one for each unit.

Split Figure 5.4-4 into separate Figures (4A and 4B), one for each unit.

Add the following NOTE to Figure 5.4-13:

"The snubbers exist only on Unit 2. They have been removed from Unit 1."

LDCR-SA-2006-40, EVAL-2003-002426-20 (RJK) (continued):

Updated discussion of Compliance with BTP RSB 5-1 (Diablo Canyon RHR comparison) in Section 5A to reflect separate calculations for each unit.

Update chart in Section 12.1 to reflect differing cobalt Wgt% for Unit 1 RSG tubes.

Update discussion in Section 12.3 of SG tubing materials to reflect RSGs and material selection.

Update Section 1.2.2 nominal performance characteristics of NSSS to reflect RSGs in Unit 1. Includes addition of two new reference documents into new section 1.2.2.13.

Justification:

- Reflects system design modification made by the Steam Generator Replacement Project (SGRP) as defined in FDA-2005-000659-02, FDA-2005-000659-03 and FDA-2003-002426-01. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and/or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

editorial change on page 5.3-4 to correct typographic error

Justification:

- Typographic error only, no change in technical content.

LDCR-SA-2006-37, EVAL-2003-002426-17 (JCH):

Insert the following into Section 10.3.2.2, "Atmospheric Relief Valves":

In Unit 1 the Westinghouse steam generators model D-4 have been replaced with a newer model D-76. Two solenoid valves are installed for each ARV. These solenoid valves are supplied from the opposite train power supply. These solenoid valves are operated from a key locked hand switch in the main control room to open the ARVs.

During a Unit 1 steam generator fault, if normal DC power is lost to the Train A or B buses, the ARVs can still be opened if required from the opposite train power to cool and depressurize the reactor and terminate primary to secondary leak.

Justification: The replacement steam generators (RSGs) installed in Unit 1 are physically different than the original SGs and when the SGTR analysis was revised to reflect the thermal hydraulic performance of the RSGs under the accident conditions, one ARV was not sufficient for the primary side cooldown and additional relief capacity is required.

In Section 10.4.8.1.1, change the total combined blowdown flow for Unit 1 from "69, 600" to "155,620".

LDCR-SA-2006-37, EVAL-2003-002426-17 (JCH) (continued):

Justification: RSG have higher SGBD flow.

Added "balancing" before "valves HV-5175 through HV-5178".

Add the following sentence:

"Once the balancing valves are set they are locked in position and do not change.

Justification: clarification on how to set blowdown for each steam generator.

LDCR-SA-2006-38, EVAL-2003-002426-18 (JCH):

DESCRIPTION: Appendix 3B

Page 3B-ii: For computer program 44 delete "*" before "ME215" and insert "(ME101FE)" after "ME215.

Page 3B-iv: Section 3.44 delete "*" before "ME215" and insert "(ME101FE)" after "ME215.

Page 3B-54: Insert "(ME101FE)" after "ME215" in the section title and in the first paragraph and delete "(Unit 2 only)" in the section title.

JUSTIFICATION:

Reflects system design modification made by the Steam Generator Replacement Project as defined in FDA-2005-000224-01, -02, -03, -04, -05, -06 and FDA-2003-002426-01.

These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and /or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

DESCRIPTION: Section 3.6B

3.6B.1.2.3.E - Break Exclusion Areas (Feedwater)

Page 3.6B-7 second paragraph last sentence after "..... region" insert "(Unit 2 only)" since the feedwater bypass piping has been eliminated for the Unit 1 RSG.

3.6B.2.2.2 - High - Energy Piping Other Than RCS Main Loop

Page 3.6B-22 second paragraph first sentence insert "or 34" after "[6" for new Reference 34 and in the last sentence after "[29]" insert "or other" and delete the comma and after "programs to" insert "the."

LDCR-SA-2006-38, EVAL-2003-002426-18 (JCH) (continued):

Page 3.6B-23 first paragraph first sentence after "[30" insert "or 35" for new Reference 35.

Page 3.6B-53 add new References 34 and 35. Reference 34 is "RELAP5/MOD 3.2, NUREG/CR-5535, June 1995" and Reference 35 is "ANSYS, Version 8.1."

3.6B.2.5.2.2 - Feedwater System - A. General Description

Page 3.6B-40 after first sentence insert "Due to the Unit 1 RSG installation the 18" x 16" reducing elbow material at the RSG nozzle inlet is now SA-508, Grade 2, Class 1."

3.6B.2.5.2.3 - Auxiliary Feedwater System - D. Environmental Analysis

Page 3.6B-43 after "".....250F maximum" insert "(Unit 2 only)."

JUSTIFICATION:

Reflects system design modification made by the Steam Generator Replacement Project as defined in FDA-2005-000224-01, -02, -03, -04, -05, -06 and FDA-2003-002426-01. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and /or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

DESCRIPTION:

For convenience the main steam system, steam generator blowdown system and miscellaneous FSAR figures pertaining to stress node break point and restraint location have been included in this EVAL.

Fig 3.6B-11 - Main Steam System: Loop 1 Inside Containment Stress Node Break Point and Restraint Location

Changed break 8C stress point to 22 and break 1C stress point to SGB and revised the legend.

Fig 3.6B-12 - Main Steam System: Loop 2 Inside Containment Stress Node Break Point and Restraint Location

Changed break 13C stress point to 28 and break 9C stress point to SGB and revised the legend.

Fig 3.6B-13 - Main Steam System: Loop 3 Inside Containment Stress Node Break Point and Restraint Location

LDCR-SA-2006-38, EVAL-2003-002426-18 (JCH) (continued)

Changed break 14C stress point to N03 and revised the legend.

Fig 3.6B-14 - Main Steam System: Loop 4 Inside Containment Stress Node Break Point and Restraint Location

Changed break 29C stress point to 800 and revised the legend.

Fig 3.6B-19 - Feedwater System: Loop 1 Inside Containment Stress Node Break Point and Restraint Location

Changed break 401C stress point to D04 and break 410C stress point to V09. Revised the notes and legend. Added snubbers and spring hangers to the drawing and deleted split flow bypass line. Revised piping for elevated RSG FW nozzle and deleted chemical feed system piping. Deleted lines capped.

Fig 3.6B-20 - Feedwater System: Loop 2 Inside Containment Stress Node Break Point and Restraint Location

Changed break 411C stress point to 50 and break 418C stress point to B50. Revised notes and legend. Added snubbers, rigid restraints and spring hangers to the drawing and deleted split flow bypass line. Revised piping for elevated RSG FW nozzle and deleted chemical feed system piping. Deleted lines capped.

Fig 3.6B-21 - Feedwater System: 1-3 Inside Containment Stress Node Break Point and Restraint Location

Changed break 414C stress point to H01 and break 434C stress point to V09. Revised notes and legend. Added snubbers, rigid restraints and spring hangers to the drawing and deleted split flow bypass line. Revised piping for elevated RSG FW nozzle and deleted chemical feed system piping. Deleted lines capped.

Fig 3.6B-22 - Feedwater System: Loop 4 Inside Containment Stress Node Break Point and Restraint Location

Changed break 421C stress point to 35 and break 429C stress point to N02. Revised notes and legend. Added snubbers, rigid restraints and spring hangers to the drawing and deleted split flow bypass line. Revised piping for elevated RSG FW nozzle and deleted chemical feed system piping. Deleted lines capped.

Fig 3.6B-26 - Aux. F.W. System Stress Node Break Point and Restraint Location (Units 1 and 2)

Revised to show preheater bypass lines (6-FW-1-91-2003-2 through 6-FW-1-94-2003-2) are for Unit 2 only.

LDCR-SA-2006-38, EVAL-2003-002426-18 (JCH) (continued)

Fig 3.6B-27 - Auxiliary F.W. System: Loop 1 Outside Containment Stress Node Break Point and Restraint Location

Deleted preheater bypass line with a capped pipe section and revised the legend.

Fig 3.6B-28 - Auxiliary F.W. System Outside Containment Stress Node Break Point and Restraint Location

Deleted preheater bypass line with a capped pipe section and revised the legend.

Fig 3.6B-29 - Auxiliary F.W. System: Loop 3 Outside Containment Stress Node Break Point and Restraint Location

Deleted preheater bypass line with a capped pipe section and revised the legend.

Fig 3.6B-30 - Auxiliary F.W. System Outside Containment Stress Node Break Point and Restraint Location

Deleted preheater bypass line with a capped pipe section and changed break 575C stress point to 34J. Revised the legend.

Fig 3.6B-34 - Feedwater System: Loop 1 Inside Containment Stress Node Break Point and Restraint Location

Changed break 597C stress point to 30 and break 598C to stress point B63. Deleted break 599C. Deleted split flow bypass line. Revised piping to the RSG AFW nozzle. Indicated that the chemical feed system and drain piping 2-1303-2 are eliminated. Drain piping 2-1303-2 was previously eliminated. Revised the legend and deleted 1-152A from the title block.

Fig 3.6B-35 - Feedwater System: Loop 2 Inside Containment Stress Node Break Point and Restraint Location

Changed break 628C stress point to 77 and break 629C to stress point 152. Deleted break 630C. Deleted split flow bypass line. Revised piping to the RSG AFW nozzle. Deleted chemical feed system piping. Deleted drain piping 2-1303-2 (previously eliminated). Revised the legend.

Fig 3.6B-36 - Feedwater System: Loop 3 Inside Containment Stress Node Break Point and Restraint Location

Changed break 622C stress point to A10 and break 623C to stress point NZ3. Deleted break 624C. Deleted split flow bypass line. Revised piping to the RSG AFW nozzle. Deleted chemical feed system piping. Deleted drain piping 2-1303-2 (previously eliminated). Revised the legend and deleted 1-154A from the title block.

LDCR-SA-2006-38, EVAL-2003-002426-18 (JCH) (continued)

Fig 3.6B-37 - Feedwater System: Loop 4 Inside Containment Stress Node Break Point and Restraint Location

Changed break 575C stress point to 34J and break 577C to stress point N03. Deleted break 576C. Deleted split flow bypass line. Revised piping to the RSG AFW nozzle. Deleted chemical feed system piping. Deleted drain piping 2-1303-2 (previously eliminated). Revised the legend.

Fig 3.6B-38 - STM. GEN. Blowdown Sys. Loop 1 Inside Containment Stress Node Break Point and Restraint Location

Changed break 202C stress point to A80, break 203C stress point to W85 and break 201C to stress point Q68. All intermediate breaks are deleted (21C, 22C, 48C, 113C, 116C, 117C, 139C, 205C, 206C, 208C, 1101C, 1160C, 1600C, 2100C and 8100C). Revised piping from the RSG blowdown and supplemental blowdown connections. Revised the legend.

Fig 3.6B-39-1 - STM. GEN. Blowdown Sys. Loop 2 Inside Containment Stress Node Break Point and Restraint Location

Changed break 192C stress point to 260, break 185C stress point to E01 and break 184C to stress point B67. All intermediate breaks are deleted (200C, 1127C/L, 1903C and 9006C). Revised piping from the RSG blowdown and supplemental blowdown connections. Revised the legend.

Fig 3.6B-40 - STM. GEN. Blowdown System Loop 3 Inside Containment Stress Node Break Point and Restraint Location

Changed break 45C stress point to 545. Intermediate break 9624C/L is deleted. Revised piping from the RSG blowdown and supplemental blowdown connections. Revised the legend.

Fig 3.6B-41 - STM. GEN. Blowdown System Loop 4 Inside Containment Stress Node Break Point and Restraint Location

Revised piping from the RSG blowdown and supplemental blowdown connections. Deleted chemical feed system piping. Revised the legend.

Fig 3.6B-55 - Safety Injection System Inside Containment Stress Node Break Point and Restraint Location

Break 8TCA moved to downstream side of check valve 1SI-8819C.

Fig 3.6B-67-1 - Reactor Coolant System Inside Containment Stress Node Break Point and Restraint Location

LDCR-SA-2006-38, EVAL-2003-002426-18 (JCH) (continued)

Breaks 71C, 72C, 73C, 80C, 81C, 82C, 83C, 96C, 140C and 142C where revised to 4370, 88, 89, 1105, 5210, 105, 106, 82, 102/1115 and 85/82 respectively.

Fig 3.6B-82-1 - CVCS Outside Containment Stress Node Break Point and Restraint Location

Deleted breaks 1421-1C and 2C based on piping analyses (CS-1-046A-PB, Rev. 4). Added pipe break analysis calculation (CS-1-042A-PB, Rev. 2) to provide the source for break 1324C inside the Reactor Building illustrated on Isometric 1-46A.

Figure 3.6B-208 - Safeguard Building Main Steam & Feedwater Lines Arrangement

Sheet 2 of 3 show that the preheater bypass lines 6-FW-1-091-2003-2 through 6-FW-1-094-2003-2 are for Unit 2 only.

Sheet 3 of 3 Sections "53-53" and "54-54" show that the preheater bypass lines 6-FW-1-091-2003-2 through 6-FW-1-094-2003-2 are for Unit 2 only.

JUSTIFICATION:

Reflects system design modification made by the Steam Generator Replacement Project as defined in FDA-2005-000224-01, -02, -03, -04, -05, -06 and FDA-2003-002426-01. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and /or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

DESCRIPTION: Table 3.6B-1 - High Energy Line List (See Notes 22 and 23)

Page 11 of 31:

These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and /or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

DESCRIPTION:

Table 10.3-6 - Materials of Main Steam and Feedwater Valves and Piping

Sheet 2 of 2: Under "Fittings", "3 in. to 24 in." insert a superscript "1" for Note 1 after "WPL-6" and insert the following after the "Flanges" section "Notes: 1. Due to the Unit 1 RSG installation the 18" x 16" reducing elbow material at the RSG nozzle inlet is now SA-508, Grade 2, Class 1."

JUSTIFICATION:

Reflects system design modification made by the Steam Generator Replacement Project as defined in FDA-2005-000224-01, -02, -03, -04, -05, -06 and FDA-2003-002426-01. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and /or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

DESCRIPTION:

10.4.7.2. - 2. Feedwater System

Page 10.4-32: Sixth paragraph first sentence revise sentence to include "When originally constructed both Unit 1 and Unit 2 incorporated a Feedwater Bypass System on each main feedwater line to a steam generator."

Insert the following paragraph: "With the installation of Delta 76 steam generators on Unit 1, the Feedwater Bypass System is no longer required by the new feedring steam generators and with the exception of the small bypass line around the main feedwater isolation valve has been totally removed from Unit 1. (Note: The Unit 1 feedwater system is operated in a different manner after RSG installation. The FIV remains open during

LDCR-SA-2006-38, EVAL-2003-002426-18 (JCH) (continued)

startup and a small flow through the valve and not the FIBV is used for purging purposes.) Unit 2 however still retains the Feedwater Bypass System in its entirety."

Add "The Unit 2" after paragraphs discussing feedwater bypass system, feedwater preheater bypass line, and feedwater split flow bypass line.

10.4.7.2 - 3. Electrical Systems

Page 10.4-33: After "The split flow bypass valves," "feedwater split flow bypass valves" and "preheater bypass valves" insert "(Unit 2 only)."

10.4.7.3 - Safety Evaluation

Page 10.4-34: Insert the following paragraph- "The Unit 1 Delta 76 Feedring RSGs incorporate a feedring design in lieu of a preheater design and this feedring design feature prevents or mitigates the possibility of a steam generator water hammer event. (CP1-RSG-05-184)."

Page 10.4-34 & 35: Insert reference to Unit 2 on the paragraphs discussing waterhammer.

10.4.7.5 - Instrumentation Requirements

Page 10.4-37: Insert the following-"Based on section 10.4.7.3 Unit 1 does not require any instrumentation to mitigate feedline water hammer. The Unit 1 feedwater system is operated in a different manner after RSG installation. The FIV remains open during startup and a small flow through the valve and not the FIBV is used for purging purposes."

10.4.7.5 - 3. Feedwater Split Flow Bypass Valve (FSBV).

Page 10.4-39: Second sentence after "open" insert "at about 30 percent RTP due to system hydraulics" and delete "ever" from "whenever."

JUSTIFICATION:

Reflects system design modification made by the Steam Generator Replacement Project as defined in FDA-2005-000224-01, -02, -03, -04, -05, -06 and FDA-2003-002426-01. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and /or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

DESCRIPTION:

10.4.9.1 - Design Bases

LDCR-SA-2006-38, EVAL-2003-002426-18 (JCH) (continued)

Page 10.4-45: Second paragraph first sentence insert "1106 psia (Unit 1) or" after "100 psia to" and insert "(Unit 2)" after "1107 psia."

Page 10.4-46: Insert the following at the end of Section 10.4.9.1:

Unit 1

"On Unit 1 the steam generators have been replaced with a model Delta 76 that employs a feedring design that eliminates the preheater. Auxiliary feedwater and feedwater entering the steam generator merge with the saturated liquid removed by the moisture separators. The combined feed then flows down the annulus formed by the steam generator shell and the tube bundle wrapper where it enters the tube bundle.

To ensure that steam does not flow back through either the main and auxiliary feedwater nozzles, the steam generator water level should be above the feedring at all operating levels where steam formation can occur. The operator is cautioned to maintain the normal SG level above the feedring at normal operating conditions. The normal operating Narrow Range level indication of 60% to 75% would result in sufficient water inventory to maintain the feedring and the AFW vertical perforated spray pipe submerged during the majority of expected transients like +/-10% load changes, turbine synchronizations, and plant loadings/unloadings. The supply piping to the auxiliary nozzle is designed with a loop seal immediately upstream of the SG nozzle to prevent steam backleakage.

In the event that steam does flow back past the loop seal and the check valves in the auxiliary feedwater line to the upper nozzle, the temperature of this line will increase causing temperature elements in the line to alarm in the control room. This allows the operator to take action to resolve the problem.

Unit 2

The Auxiliary Feedwater System is designed to preclude the effects of hydraulic instability due to water hammer by supplying water to the secondary side of the steam generator through a separate upper auxiliary feedwater nozzle. The Unit 2 preheater design steam generators permit the cold auxiliary feedwater to be heated as it comes down the side of the steam generator prior to reaching the feedwater preheater. For further discussion of the feedwater system upper nozzle arrangement and considerations see Subsection 10.4.7.

To ensure that steam does not flow back to the auxiliary feedwater nozzle, the steam generator water level should be above the auxiliary feedwater discharge pipe at all operating levels where steam formation can occur. Therefore, the operator is cautioned to maintain SG level above the auxiliary nozzle internal pipe extension when the temperature is above 212oF. This pipe is designed with a loop seal immediately upstream of the SG nozzle to prevent steam backleakage. Forward flushing is provided through the auxiliary feedwater nozzle virtually at all loads by AFW flow at startup

LDCR-SA-2006-38, EVAL-2003-002426-18 (JCH) (continued)

conditions, by preheater bypass flow during initial power ascension and by the split flow of the feedwater at RTPs above 30% full load.

In the event that steam does flow back past the loop seal and the check valves in the feedwater line to the upper nozzle, the temperature of this line will increase causing temperature elements in the line to alarm in the control room. This allows the operator to take action to resolve the problem.

10.4.9.2 - System Description

Page 10.4-47: Delete the paragraph beginning with "Downstream of the last isolation valve....." t

Page 10.4-48: Insert the following at the end of Section 10.4.9.2-

Unit 1

Downstream of the last isolation valve, each line from the motor-driven pumps joins with a corresponding line from the turbine driven pump to form a common line that connects with the feedwater line that connects to the auxiliary nozzle on the Unit 1 steam generator."

Unit 2

Downstream of the last isolation valve, each line from the motor-driven pumps joins with a corresponding line from the turbine driven pump to form a common line that connects with the feedwater preheater bypass line. The preheater bypass line connects to the Unit 2auxiliary nozzle on the steam generator."

10.4.9.3 - Safety Evaluation

Page 10.4-50: Insert "For Unit 2" at the start of the last paragraph

JUSTIFICATION:

Reflects system design modification made by the Steam Generator Replacement Project as defined in FDA-2005-000224-01, -02, -03, -04, -05, -06 and FDA-2003-002426-01. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and /or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

DESCRIPTION:

Figure 10.4-12 - Auxiliary Feedwater Failure Mode Analysis Flow Diagram

LDCR-SA-2006-38, EVAL-2003-002426-18 (JCH) (continued):

A dotted line was placed around the main feedwater piping to the SG to the preheater bypass piping and back to the main feed system identification block and text added that is "For Unit 2 Only."

Figure 10.4-22 - Main Feedwater Loop Seal Arrangement

Figure 10.4-22 was revised for Unit 1 and Unit 2. Figure 10.4-22A is for Unit 1 and is a new Figure. Figure 10-4-22B is the current figure with the title block revised to show "Unit 2" only and the a "B" added to Figure 10.4-22.

JUSTIFICATION:

Reflects system design modification made by the Steam Generator Replacement Project as defined in FDA-2005-000224-01, -02, -03, -04, -05, -06 and FDA-2003-002426-01. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and /or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

DESCRIPTION:

Figure II.E.1.1-1 - Auxiliary Feedwater System Simplified Flow Diagram

A dotted line was place around the main feedwater piping to the SG to the preheater bypass piping and back to the main feed water identification block and text added that is "For Unit 2 Only."

JUSTIFICATION:

Reflects system design modification made by the Steam Generator Replacement Project as defined in FDA-2005-000224-01, -02, -03, -04, -05, -06 and FDA-2003-002426-01. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and /or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

LDCR-SA-2006-39, EVAL-2003-002426-19 (JDS):

9.1.4.2.2 - Refueling Procedure

Item 2 - Phase II Reactor Disassembly

Insert the following sentence before the current first sentence: "The external air duct is removed from the CRDM Ventilation System's Air Handling Units and plenum (Unit 1 only)."

LDCR-SA-2006-39, EVAL-2003-002426-19 (JDS) (continued):

Current first sentence after "shield" insert "(Unit 2 only)." Current second sentence after "Air ducts" insert "(Unit 2 only)."

Reflects system design modification made by the Steam Generator Replacement Project (SGRP) as defined in FDA-2004-002710-02, FDA-2004-002710-03, FDA-2004-0002711-01 and FDA-2003-002426-02. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and/or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

9.1.4.3.1 - Safe Handling

op paragraph next to last sentence insert "an integral steel missile shield (Unit 1 only) and a" after "employs" and insert "(Unit 2 only)" after current "shield.

Reflects system design modification made by the Steam Generator Replacement Project (SGRP) as defined in FDA-2004-002710-02, FDA-2004-002710-03, FDA-2004-0002711-01 and FDA-2003-002426-02. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and/or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

3.7N.1.3 - Critical Damping Values

Clarification added that the damping values given apply to both Units 1 and 2.

Reflects system design modification made by the Steam Generator Replacement Project (SGRP) as defined in FDA-2004-002710-02, FDA-2004-002710-03, FDA-2004-0002711-01 and FDA-2003-002426-02. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and/or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

4.5.1.1 - Materials Specifications

The Unit 1 RSG uses different stainless steel than Unit 2. Therefore, under "Pressure vessel" insert "Type F304LN for Unit 1," before "Type" and insert "for Unit 2" after "304."

Reflects system design modification made by the Steam Generator Replacement Project (SGRP) as defined in FDA-2004-002710-02, FDA-2004-002710-03, FDA-2004-0002711-01 and FDA-2003-002426-02. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and/or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

LDCR-SA-2006-39, EVAL-2003-002426-19 (JDS) (continued):

TMI II.F.2.3 - Reactor Coolant System Temperature

This revision indicates the differences between Unit 1 and Unit 2 in the location of the complete core exit thermocouples (CET) cable train separation. Therefore, the following changes are identified: In the next to last sentence on Page II.F-5 insert "CRDM Seismic Support Assembly's platform (Unit 1) and the missile" and insert "(Unit 2)" after "shield."

Reflects system design modification made by the Steam Generator Replacement Project (SGRP) as defined in FDA-2004-002710-02, FDA-2004-002710-03, FDA-2004-0002711-01 and FDA-2003-002426-02. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and/or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

Table 17A-1 - List of Quality Assured Structures, Systems and Components

After "Control rod drive mechanism…" insert a new row as follows: "CRDM air cooling shroud assemblies (Unit 1 only), NNS, Mfrd Stds, - , II, Note E, and Note 10" respectively.

After "CRDM air cool baffle assemblies" insert "(Unit 2 only)."

After "Roll-away missile shield" insert "(Unit 2 only)."

Reflects system design modification made by the Steam Generator Replacement Project (SGRP) as defined in FDA-2004-002710-02, FDA-2004-002710-03, FDA-2004-0002711-01 and FDA-2003-002426-02. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and/or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

3.8.3.4.1 General Analysis of Internal Structure

Section revised to indicate that the STRUDL computer program was used for the evaluation of the Unit 1 steam generator compartments.

Reflects system design modification made by the Steam Generator Replacement Project (SGRP) as defined in FDA-2004-002710-02, FDA-2004-002710-03, FDA-2004-0002711-01 and FDA-2003-002426-02. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and/or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

LDCR-SA-2006-39, EVAL-2003-002426-19 (JDS) (continued):

Table 3.8-1 Summary Table for Category 'I' Structures

Table was revised to include the latest stresses for the Unit 1 Reactor Building and steam generator upper lateral support beam. Revised loads due to the Replacement Steam Generator necessitated that these structures be re-analyzed.

Reflects system design modification made by the Steam Generator Replacement Project (SGRP) as defined in FDA-2004-002710-02, FDA-2004-002710-03, FDA-2004-0002711-01 and FDA-2003-002426-02. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and/or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

5.3.1.2 - Special Processes Used for Manufacturing and Fabrication

Divide Item 3 into a Unit 1 and Unit 2 section as follows: Insert paragraph "A: Unit 1" and the following: "The surfaces of the guide studs are chrome plated to prevent possible galling of the mated parts." Before the existing sentence insert "B: Unit 2."

Divide Item 6 into a Unit 1 and Unit 2 section as follows: Insert paragraph "A: Unit 1" and the following: "The location of full penetration weld seams in the vessel bottom head are restricted to areas that permit accessibility during inservice inspection. There are no full penetration welds in the upper closure head." Before the existing sentence insert "B: Unit 2."

Reflects system design modification made by the Steam Generator Replacement Project (SGRP) as defined in FDA-2004-002710-02, FDA-2004-002710-03, FDA-2004-0002711-01 and FDA-2003-002426-02. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and/or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

5.3.3.1 - Design

First paragraph delete "The reactor vessel closure head" and insert the following the following for Unit 1 and Unit 2: Insert "A: Unit 1" and the following paragraph "The Unit 1 reactor vessel closure head contains head adapters. These head adapters are tubular members, attached by partial penetration welds to the underside of the closure head. The upper end of these allow for welding to the control rod drive mechanisms. There are also two penetrations for the Reactor Vessel Level Measuring System (RVLMS) and four penetrations for the Core Exit Thermocouple Nozzle Assemblies (CETNA)." Insert "B. Unit 2" and "The Unit 2 reactor vessel closure head" before the existing "contains head adapters."

LDCR-SA-2006-39, EVAL-2003-002426-19 (JDS) (continued):

Reflects system design modification made by the Steam Generator Replacement Project (SGRP) as defined in FDA-2004-002710-02, FDA-2004-002710-03, FDA-2004-0002711-01 and FDA-2003-002426-02. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and/or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

5.3.3.5 - Shipment and Installation

After the first paragraph insert Unit 1 and Unit 2 paragraphs as follows: Insert "A. Unit 1" and the following paragraph: "The Unit 1 replacement closure head is shipped with a protective shipping cover and skid. Two support plates within the shipping cover protect the control rod drive mechanism housings. All head openings are sealed to prevent the entrance of moisture and an adequate quantity of desiccant bags are placed inside the head. In addition, nitrogen purge is maintained to protect the control rod drive mechanism internals. The shipping cover also acts as a lifting frame for handling the replacement closure head." Inset "B. Unit 2" and then insert "Unit 2" before "closure head" of the existing paragraph.

Reflects system design modification made by the Steam Generator Replacement Project (SGRP) as defined in FDA-2004-002710-02, FDA-2004-002710-03, FDA-2004-0002711-01 and FDA-2003-002426-02. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and/or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

5.3.3.7 - Inservice Surveillance

The HAUP design does not include a knuckle transition piece. Therefore revise as follows: Second paragraph third sentence insert "For Unit 2," and delete "T" and insert "t" at the beginning of the sentence.

Reflects system design modification made by the Steam Generator Replacement Project (SGRP) as defined in FDA-2004-002710-02, FDA-2004-002710-03, FDA-2004-0002711-01 and FDA-2003-002426-02. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and/or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

5.3.3.8 - Degradation of Control Rod Drive Mechanism Nozzle and Other Vessel Closure Head Penetrations (GL 97-01)

The Unit 1 RRVCH uses material Alloy 690. Therefore insert the following after the first paragraph making the remainder of the section applicable to Unit 2: "A: Unit 2 (Unit 1 RRVCH replaced Alloy 600 with Alloy 690)."

LDCR-SA-2006-39, EVAL-2003-002426-19 (JDS) (continued):

Reflects system design modification made by the Steam Generator Replacement Project (SGRP) as defined in FDA-2004-002710-02, FDA-2004-002710-03, FDA-2004-0002711-01 and FDA-2003-002426-02. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and/or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

3.9N.4.1 - Descriptive Information of CRDS

ivide item 1 first paragraph into a paragraph for the Unit 1 RSG and Unit 2.

Insert "A. Unit 1" and the following paragraph" "For Unit 1, the pressure vessel is a one-piece housing which is connected to the reactor vessel head adapters by a full penetration weld. The lower portion of the pressure vessel contains the latch assembly. The upper portion of the pressure vessel provides space for the drive rod during its upward movement as the control rods are withdrawn from the core."

Item 2 second paragraph after "housing" in both sentences insert "/pressure vessel."

Second paragraph after item 4 insert "A. Unit 1" and the following paragraph "The Unit 1 control rod drive mechanism is welded with a full penetration weld to an adaptor on top of the reactor vessel and is coupled to the rod cluster control assembly directly below." Then insert "B. Unit 2" and insert "Unit 2" after "The" in the existing first sentence.

Fifth paragraph after item 4 after "housing" insert "/pressure vessel."

Reflects system design modification made by the Steam Generator Replacement Project (SGRP) as defined in FDA-2004-002710-02, FDA-2004-002710-03, FDA-2004-0002711-01 and FDA-2003-002426-02. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and/or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

3.9N.4.3.3 - Latch Assembly and Coil Stack Assembly

Unit 1 RSG and Unit 2 have different stainless steel materials.

Under "Latch Assembly - Thermal Clearances" first sentence insert "Type F304LN (Unit 1) or" before "Type 304" and insert "(Unit 2)" after "Type 304."

First, second and third paragraph under "Coil Stack Assembly - Thermal Clearances" after "latch housing" insert "/pressure vessel."

LDCR-SA-2006-39, EVAL-2003-002426-19 (JDS) (continued):

Reflects system design modification made by the Steam Generator Replacement Project (SGRP) as defined in FDA-2004-002710-02, FDA-2004-002710-03, FDA-2004-0002711-01 and FDA-2003-002426-02. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and/or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

3.9N.4.1 - Descriptive Information of CRDS

Divide item 1 first paragraph into a paragraph for the Unit 1 RSG and Unit 2.

Insert "A. Unit 1" and the following paragraph" "For Unit 1, the pressure vessel is a one-piece housing which is connected to the reactor vessel head adapters by a full penetration weld. The lower portion of the pressure vessel contains the latch assembly. The upper portion of the pressure vessel provides space for the drive rod during its upward movement as the control rods are withdrawn from the core."

Reflects system design modification made by the Steam Generator Replacement Project (SGRP) as defined in FDA-2004-002710-02, FDA-2004-002710-03, FDA-2004-0002711-01 and FDA-2003-002426-02. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and/or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

6.2.2.3.3 - Recirculation Sump Design

Clarification of location of the Unit 1 RSG and respective piping accelerations. Page 6.2-38, third paragraph, after first sentence insert "As a result of the Steam Generator Replacement Project, the accelerations for the Unit 1 steam generators, the new main feedwater piping and the new auxiliary feedwater piping are location specific.."

Reflects system design modification made by the Steam Generator Replacement Project (SGRP) as defined in FDA-2004-002710-02, FDA-2004-002710-03, FDA-2004-0002711-01 and FDA-2003-002426-02. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and/or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

Appendix 1A(B) -- Regulatory Guide 1.75

The discussion regarding compliance with Regulatory Position C.9 of Regulatory Guide 1.75 was modified to include the CRDM cable splices being installed in cable trays as part of FDA-2004-002710-02. In addition, a reference was added to Section 8.3, which addresses reduced separation requirements for instrumentation cables.

LDCR-SA-2006-39, EVAL-2003-002426-19 (JDS) (continued):

Reflects system design modification made by the Steam Generator Replacement Project (SGRP) as defined in FDA-2004-002710-02, FDA-2004-002710-03, FDA-2004-0002711-01 and FDA-2003-002426-02. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and/or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

8.3.1.4 - Independence of Redundant Systems

A paragraph was added to state that, in plant areas free from potential hazards such as missiles, external fires, and pipe whip and in non-hazard areas, the minimum separation the minimum separation between redundant instrumentation cables/trays is one inch horizontally and three inches vertically.

Reflects system design modification made by the Steam Generator Replacement Project (SGRP) as defined in FDA-2004-002710-02, FDA-2004-002710-03, FDA-2004-0002711-01 and FDA-2003-002426-02. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and/or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

3.7N.1.3 - Critical Damping Values

Clarification added that the damping values given apply to both Units 1 and 2.

Reflects system design modification made by the Steam Generator Replacement Project (SGRP) as defined in FDA-2004-002710-02, FDA-2004-002710-03, FDA-2004-0002711-01 and FDA-2003-002426-02. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and/or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

Table 3.9N-20 - CRDM Head Adaptor Bending Moments

Actual versus allowable bending moments for the new Unit 1 CRDM Head Adaptors are provided in this Table

Reflects system design modification made by the Steam Generator Replacement Project (SGRP) as defined in FDA-2004-002710-02, FDA-2004-002710-03, FDA-2004-0002711-01 and FDA-2003-002426-02. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and/or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

LDCR-SA-2006-39, EVAL-2003-002426-19 (JDS) (continued):

Table 5.3-1 - Reactor Vessel Quality Assurance Program

Clarification added that for Unit 1, the closure head is a one-piece forging.

Reflects system design modification made by the Steam Generator Replacement Project (SGRP) as defined in FDA-2004-002710-02, FDA-2004-002710-03, FDA-2004-0002711-01 and FDA-2003-002426-02. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and/or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

7.7.1.9.1 - Thermocouples

Insert sentence after "......assemblies" "The Unit 1 thermocouples are provided with a grafoil seal and swage type seal from conduit to head." After "The" now third sentence insert "Unit 2."

Reflects system design modification made by the Steam Generator Replacement Project (SGRP) as defined in FDA-2004-002710-02, FDA-2004-002710-03, FDA-2004-0002711-01 and FDA-2003-002426-02. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and/or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

Table 5.3-5 - Reactor Vessel Design Parameters

Under "Overall height of vessel….." insert the Unit 1 RSG value and identify the Unit 2 value as follows: Insert "43-6.4 (Unit 1)" and after "-10" insert "(Unit 2)."

Under "Closure head thickness (in.)" insert the Unit 1 RSG value and identify the Unit 2 value as follows" Insert "7 (Unit 1)" and after "-1/2" insert "(Unit 2)."

Reflects system design modification made by the Steam Generator Replacement Project (SGRP) as defined in FDA-2004-002710-02, FDA-2004-002710-03, FDA-2004-0002711-01 and FDA-2003-002426-02. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and/or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

Table 5.3-15A - Unit 1 Reactor Vessel Non-Beltline Weld Metal Toughness Properties

The HAUP closure head design is not part of this table.

Delete the first four rows of this table for the HAUP. The closure head is a one piece design.

LDCR-SA-2006-39, EVAL-2003-002426-19 (JDS) (continued):

Reflects system design modification made by the Steam Generator Replacement Project (SGRP) as defined in FDA-2004-002710-02, FDA-2004-002710-03, FDA-2004-0002711-01 and FDA-2003-002426-02. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and/or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

Table 5.3-2A - Unit 1 Reactor Vessel Fracture Toughness Properties

Delete the first three rows and insert the following row as row one : "Closure Head Forging, A508, C3, - 0.05, -, 0.87, -50, 10, -50, - and 184.0 respectively.

Reflects system design modification made by the Steam Generator Replacement Project (SGRP) as defined in FDA-2004-002710-02, FDA-2004-002710-03, FDA-2004-0002711-01 and FDA-2003-002426-02. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and/or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

Table 9.4-2 - Design Conditions - Indoor

The "CRDM Shroud (Air Temperature)" at the inlet and the outlet remain the same for the HAUP/AHU and Unit 2, however Table 9.4-2 is revised to show that the HAUP/AHU inlet temperature is measured at the AHU inlet and not at the CRDM shroud as for Unit 2. Therefore, under "Reactor Containment Bldg. (RCB)" revise item 3 first column as follows: Insert "163 (CRDM Air Handling Unit inlet) (Unit 1)" before existing "163 (outlet)" and insert "(Unit 2)" after "163 (outlet)."

Reflects system design modification made by the Steam Generator Replacement Project (SGRP) as defined in FDA-2004-002710-02, FDA-2004-002710-03, FDA-2004-0002711-01 and FDA-2003-002426-02. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and/or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

5.2.3.4.4 - Prevention of Intergranular Attack of Unstabilized Austenitic Stainless Steels

Clarification added that CRDM seal welds only apply to Unit 2.

Reflects system design modification made by the Steam Generator Replacement Project (SGRP) as defined in FDA-2004-002710-02, FDA-2004-002710-03, FDA-2004-0002711-01 and FDA-2003-002426-02. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and/or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

LDCR-SA-2006-39, EVAL-2003-002426-19 (JDS) (continued):

Figure 3.9N-5 - Full Length Control Rod Drive Mechanism

The Unit 1 CRDM drive mechanism is different than the Unit 2 drive mechanism. A new figure has been developed for Unit 1 with the same title as the existing figure and the figure number has been changed to "Figure 3.9N-5A." For the existing figure delete "S 1 and" and insert "B" after the figure number in the title block for the Unit 2 CRDM.

Reflects system design modification made by the Steam Generator Replacement Project (SGRP) as defined in FDA-2004-002710-02, FDA-2004-002710-03, FDA-2004-0002711-01 and FDA-2003-002426-02. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and/or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

Figure 3.9N-6 - Full Length Control Rod Drive Mechanism Schematic

The Unit 1 CRDM drive mechanism schematic is different than the Unit 2 drive mechanism schematic. A new figure has been developed for Unit 1 with the same title as the existing figure and the figure number has been changed to "Figure 3.9N-6A." For the existing figure delete "S 1 and" and insert "B" after the figure number in the title block for the Unit 2 CRDM schematic.

Reflects system design modification made by the Steam Generator Replacement Project (SGRP) as defined in FDA-2004-002710-02, FDA-2004-002710-03, FDA-2004-0002711-01 and FDA-2003-002426-02. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and/or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

Table 3.5-6 - Internally Generated Missiles (Inside Containment)

Due to the new CRDM design on Unit 1, the Unit 1 and Unit 2 missiles and type of protection are different. Therefore, revise as follows:

First row under "Identification of Missiles" insert "Unit 1," "Missile from CRDM drive shaft" and "Unit 2" before the existing text.

First row under "Missile Protection Provided" insert "Unit 1," "Integral steel missile shield above CRDM housing" and "Unit 2" before the existing text.

Reflects system design modification made by the Steam Generator Replacement Project (SGRP) as defined in FDA-2004-002710-02, FDA-2004-002710-03, FDA-2004-0002711-01 and FDA-2003-002426-02. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and/or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

LDCR-SA-2006-39, EVAL-2003-002426-19 (JDS) (continued):

Figure 3.5-1 - Stationary Storage Scheme Roll-Away Missile Shield

This figure revised to show it is applicable to Unit 2 only. Insert "Unit 2 only" and "Unit 2" as shown on the markup.

Reflects system design modification made by the Steam Generator Replacement Project (SGRP) as defined in FDA-2004-002710-02, FDA-2004-002710-03, FDA-2004-0002711-01 and FDA-2003-002426-02. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and/or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

Figure 3.5-2 - Roll-Away Missile Shield

This figure revised to show it is applicable to Unit 2 only. Insert "Unit 2 only" and "Unit 2" as shown on the markup.

Reflects system design modification made by the Steam Generator Replacement Project (SGRP) as defined in FDA-2004-002710-02, FDA-2004-002710-03, FDA-2004-0002711-01 and FDA-2003-002426-02. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and/or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

Figure 1.2-8 - Building Cross-Section D-D

The Missile Shield and CRDM Cooling Unit have been deleted for Unit 1. Also, delete "Rev. No. 6" for drawing "A1-0529" and "Amendment 10, March 31, 1980."

Reflects system design modification made by the Steam Generator Replacement Project (SGRP) as defined in FDA-2004-002710-02, FDA-2004-002710-03, FDA-2004-0002711-01 and FDA-2003-002426-02. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and/or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

Figure 1.2-13 - Primary Plant - Unit 1 Containment & Safeguard Buildings - Plans At EL. 852'-6" and 860'-0"

The indication of the position of the Stored Rolling Missile Shield has been deleted for Unit 1. For drawing A1-0503 delete "Rev. No. 8" and insert "Sheet -." Also delete all the "Roof Details" depicted on the left side of the figure for Unit 1. This information is now located on drawing "A1-503, Sheet A."

LDCR-SA-2006-39, EVAL-2003-002426-19 (JDS) (continued):

Reflects system design modification made by the Steam Generator Replacement Project (SGRP) as defined in FDA-2004-002710-02, FDA-2004-002710-03, FDA-2004-0002711-01 and FDA-2003-002426-02. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and/or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

Figure 3.8-2 - Structural Plant Arrangement Section A-A

The Missile Shield above the reactor vessel has been deleted for Unit 1. Add note to Figure.

Reflects system design modification made by the Steam Generator Replacement Project (SGRP) as defined in FDA-2004-002710-02, FDA-2004-002710-03, FDA-2004-0002711-01 and FDA-2003-002426-02. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and/or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

Figure 3.8-15 - Containment Internal Structure

Notes added to Figure to indicate Missile Shield above reactor vessel is for Unit 2 only.

Reflects system design modification made by the Steam Generator Replacement Project (SGRP) as defined in FDA-2004-002710-02, FDA-2004-002710-03, FDA-2004-0002711-01 and FDA-2003-002426-02. These changes have been reviewed by the 50.59 process and were determined to not involve a change to an SSC that adversely affects an UFSAR described design function and/or that do not require prior NRC approval since the methodology had been previously approved by the NRC for the intended application.

LDCR-SA-2007-6, EVAL-2005-001957-21 (RJK):

Table 1.6-1, Section 4A and Section 15.6:

Update listing of approved topical reports by adding the following:

ERX-04-004-A; “Replacement Steam Generator Supplement To TXU Power's Large and Small Break Loss Of Coolant Accident Analysis Methodologies” Revision 0, March 2007.

ERX-04-005-A; “Application of TXU Power's Non-LOCA Transient Analysis Methodologies to a Feed Ring Steam Generator Design” Revision 0, March 2007.

This is part of implementation of License Amendment 135.

FSAR Amendment 101, Supplement a

LDCR-SA-2003-21, EVAL-1999-000276-07 (JCH):

Table 3.9B-10

Changed valve type for 1DD-0020 and XDD-0103 from "diaphragm" to "ball."

Replacing the diaphragm valves with ball valves provides a more robust design that is unaffected by closure agsinst system pressure thus eliminating the maintenance issue and making the system more reliable.

LDCR-SA-2007-9, EVAL-2006-003910-01 (RJK):

Replace incorrect valve numbers HV-4872 and HV-4873 with valve numbers HV-4782 and HV-4783. Corrects typographic error which transposed the digits of the valve numbers.

LDCR-SA-2006-1, EVAL-2005-003364-01 (RJK):

Section 12.3 - Barriers around the fuel transfer tube area will be removed from the plant. The primary reason to remove these barriers is to increase containment spray drainage flow to the containment sump. These non-essential metal barriers will be removed under FDA-2005-003364-07 (for Unit 2) and FDA-2005-003364-17 (for Unit 1) to support the response to GSI-191 concerns regarding containment sump operation. In order to enhance the flow from containment spray to the sumps during a postulated LOCA, these unnecessary wire mesh cages and doors will be removed.

Engineering analyses (via ME-CA-4000-0950) provided estimated dose rate projections for the RB 808' elev underneath the fuel transfer tube based on worse case source term assemblies and transient time. The results of this calculation define the dose rates at this location to be 187 mR/hr. EVAL-2002-003029-01 provides further assurance via typical field data from past fuel transfer tube activities that potential dose rates are less than that estimated in ME-CA-4000-0950 and less than the dose/dose rate limits prescribed in 10CFR20. As such, this is an acceptable change. Compliance with the requirements of TS 5.7 is provided administratively through the STAs. Therefore, removal of the barriers under the fuel transfer tube will not result in exposures to outage workers that exceed TS 5.7 limits and it is therefore an acceptable change.

LDCR-SA-2007-17, EVAL-2005-001957-20 (RJK):

Replace the reference to Figures 5.2-2 and 5.2-3 with "…the Pressure and Temperature Limits Report." Figures 5.2-2 and 5.2-3 are deleted from the FSAR.

The information contained in Figures 5.2-2 and 5.2-3 is present in the owner controlled Pressure and Temperature Limits Report, developed in accordance with Tech Spec 5.6.6. There is no reduction in control of the information. Maintaining the same information in two places is not necessary, so the information is being relocated to a more relevant document.

Delete Figure 5.2-2 from the FSAR.

The information contained in Figure 5.2-2 is present in the owner controlled Pressure and Temperature Limits Report, developed in accordance with Tech Spec 5.6.6. There is no reduction in control of the information. Maintaining the same information in two places is not necessary, so the information is being relocated to a more relevant document.

Delete Figure 5.2-3 from the FSAR.

The information contained in Figure 5.2-3 is present in the owner controlled Pressure and Temperature Limits Report, developed in accordance with Tech Spec 5.6.6. There is no reduction in control of the information. Maintaining the same information in two places is not necessary, so the information is being relocated to a more relevant document.

Add WCAP-14040 to the list of material incorporated in the FSAR by reference.

LDCR-SA-2007-17, EVAL-2005-001957-20 (RJK) (continued):

WCAP-14040 is the approved methodology as listed in Tech Spec 5.6.6 for development of the RCS H/U and C/D curves for the PTLR.

LDCR-SA-2004-30, EVAL-2004-002063-03 (TJE):

In section 1.2.2.3.5:

1. Delete all of 1.2.2.3.5 except of the last paragraph and insert the following before the last paragraph:

"Combustible gas control systems are not required to be Engineered Safety Feature Systems."

2. At the end of the last paragraph insert,

"This system purges the containment atmosphere through filters which reduce radioactive releases. See Section

6.2.5 for details."

Hydrogen recombiners are being removed consistent with the revised 10CFR50.44 and TSTF-447.

Delete the description of the hydrogen recombiners for regulatory guide 1.7 from 1A(N) and insert,

"Based on a revision to 10CFR40.44, Regulatory Guide 1.7 no longer applies to CPSES. See Section 6.2.5." Hydrogen recombiners are being removed consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

Delete description of the hydrogen recombiners for regulatory guide 1.7 in 1A(B) and insert, "Based on a revision to 10CFR40.44, Regulatory Guide 1.7 no longer applies to CPSES. See Section 6.2.5." Hydrogen recombiners are being removed consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

In section 3.1.2.7, delete discussion of the hydrogen removal system. Removal consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

In sections 3.1.4.13 and 3.1.4.14, delete discussion of the hydrogen recombiners. Removal consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

In section 6.2.5 to 6.2.5.3.1, delete discussion of the hydrogen recombiners. Removal consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

LDCR-SA-2004-30, EVAL-2004-002063-03 (TJE) (continued):

In section 6.2.5.3.3 to 6.2.5A.6, delete discussion of the hydrogen recombiners and hydrogen gas production. Removal consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

In Tables 6.2.5-1 and -2,

1. Delete Table 6.2.5-1 titled "Applicable Codes, Standards, and Regulatory Guides Used in the Design of the Electric Hydrogen Recombiner"

2.) Delete Table 6.2.5-2 titled "Electric Hydrogen Recombiner Parameters"

Removal consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

Delete Table 6.2.5-4 for zinc corrosion rate. Removal consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

Delete section 1 and 3 of Table 6.2.5-5 for FMEA for the hydrogen recombiners. Removal consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

Delete Table 6.2.5A-1 Sheets 1 to 3, Table 6.2.5A-2 Sheets 1 and 2, and Table 6.2.5A-3. Removal consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

Delete Table 6.2.5A-5 and Table 6.2.5A-6. Removal consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

In section 7.1.1.1.2., delete discussion number 4 on combustable gas control. Removal consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

On Table 7.1-2.6 sheets 1 to 4, delete the column titled "Hydrogen Monitoring." Removal consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

In section 7.2.1.2.5, delete line item 3. for explosion from hydrogen buildup. Removal consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

In section 7.3.1.2.5, delete line item 3. for explosion from hydrogen buildup. Removal consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

In section 7.3.2.2, delete the third sentence which makes reference to GDC 41 for Hydrogen recombiners. Removal consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

LDCR-SA-2004-30, EVAL-2004-002063-03 (TJE) (continued):

On Table 7.5-3, sheet 2, revise "Containment Hydrogen" Variable Function from "Key" to "Backup" and Type/Category from "B1" to "B3." On Table 7.5-4 revise "Containment Hydrogen" Variable Function from "Key to Backup" and Type/Category from "C1" to "C3". Removal consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

In Table 7.5-7A, sheet 3, revise category for containment hydrogen concentration from "B1, C1" to "B3, C3." Revision consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

Identify deviation from RG 1.97 for hydrogen monitors.

On Table 7.5-7D, Sheet 7, at the bottom of the page starting from the first column add "Hydrogen Monitor," second column add "Category," third column add "Category 1," forth column add "Category 3," and the last column add "(24)."

Consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

Incorporate commitment to maintain hydrogen monitors capable of diagnosing beyond design bases accidents.

In Table 7.5-7E, Sheet 1 and 3,

1.) Remove the reference of "Containment Hydrogen Concentration" in numbers (3) on Sheet 1 and (19) on Sheet 3.

2.) Also on Sheet 3, iin number (19), second sentence, replace the word "are" with "is," and add "and License Amendment 117" at the end of number (24)

Consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

On Table 8.1-1 sheet 1, delete reference to hydrogen recombiner and containment hydrogen purge system. Consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

For Table 8.3-1,

On Sheet 7, remove the reference to

1.) Electric H2 Recombiner Power Supply Panel (Post Accident) and

2.) Hydrogen Purge Exhaust Fan Filter Heater

LDCR-SA-2004-30, EVAL-2004-002063-03 (TJE) (continued):

On Sheet 8 of the same table above, remove the reference to

1.) Containment Hydrogen Purge Air Exhaust Fan.

On Sheet 9 of the same table above,

1.) Replace Specific Notes 12. and 13 with the words "Not used."

Include hydrogen recombiners to non class 1E equipment connected to safety related bus and footnote to assure remains disconnected during modes where the bus is required to be operable by technical specifications. Consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

In Table II.B.2-4 sheet 4, delete reference in number 15 to hydrogen recombiner. Consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

Delete reference 15 to powering up hydrogen recombiner on Sheets 2, 4, 6, 7, 9, 10, and 12 of Table II.B.2-5. Consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

Delete references 15A and 15B to powering up the hydrogen recombiner on Sheets 2, 5, 7, 9, 11, and 13 of Table II.B.2.-6. Consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

In section II.E.4.1 replace the CPSES Response with "Post accident combustible gas control vis external hydrogen purge or internal electric hydrogen recombiners is no longer required as described in Section 6.2.5. See Section 6.2.4 for containment penetration isolation." Consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

In section II.F.1.6, delete reference to hydrogen monitors as required and refer to section 6.2.5.2.3 and 7.5 for required commitment related to the monitors. Consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

Delete the reference to "Electric Hydrogen Recombiner EQDP-SP-1" from Table 3.10N-1. Consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

In Chapter 6 Table of Contents, delete Sections, "6.2.5A.1 to 6.2.5A.6." Consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

In Chapter 6 List of Tables, replace the title of numbers, 6.2.5-1, 6.2.5-2, 6.2.5-4, 6.2.5A-1, 6.2.5A-2, 6.2.5A-3, 6.2.5A-5, and 6.2.5A-6 with the words "This Table has been deleted." Consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

LDCR-SA-2004-30, EVAL-2004-002063-03 (TJE) (continued):

In Chapter 6 List of Figures, replace figure titles of 6.2.5-2, 6.2.5A-1, 6.2.5A-2, 6.2.5A-3, and 6.2.5A-5 with the word "Deleted." Consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

In Chapter 6 List of Figures, replace the title of Numbers 6.2.5A-7, and 6.2.5A-9 with the words "Deleted." Consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

In Section 6.2.5.3.2.3 , delete the third paragraph which reads,

"After 30 days, the hydrogen generation rate from core radiolysis is 0.68 scfm. The generation rates from sump radiolysis and corrosion are 0.175 scfm, and 2.38 scfm, respectively."

Consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

On page 6.2-80, delete the entire References. Consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

Add the words "Abandoned in Place" at the top of Figure 6.2.5-1. Consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

Delete Figure 6.2.5-2. Consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

Delete Figures 6.2.5A-1, -02, and -03. Consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

Delete the Figures 6.2.5A-5, -7, and -9. Consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

In section 7.6.9,

1. replace the word "DBA" with "severe accident" and delete the word "System" in the first sentence of the first paragraph.

2.) delete the sentences in 7.6.9.1 and 7.6.9.2.

3.) delete the following words from the last paragraph, "System, which includes Hydrogen Monitoring, Hydrogen Recombiners and the Hydrogen Purge System."

Consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

On Table 8.3-2, sheet 5, delete the Reference to "Electric H2 Recombiners Power Supply Panel. Consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

LDCR-SA-2004-30, EVAL-2004-002063-03 (TJE) (continued):

On Table 8.3-2, sheet 12, replace Notes 12 and 13 with the words "Not used." Consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

From T 13.5-2 sheet 1, remove the reference to "Electric Hydrogen Recombiner System." Consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

In Section 15.6.5.4.5, remove the reference to "hydrogen purge system" and "electric hydrogen recombiners." Consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

In Table 17A-1, sheet 11, under number 9.a and in the 2nd and 3rd column, replace with "NA." Under the 5th column, replace the seismic category "I" with "II." Change the 6th column from "Note A" to "Note B." Consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

In Sections 6.2.5.3.2.3 and 6.2.5.3.2.4,

a. Relocate 6.2.5.3.2.3.b "Reactor Cavity" to 6.2.5.3.2.4.c,

b. Relocate 6.2.5.3.2.4.a "Pressurizer Subcompartment" to 6.2.5.3.2.3.b

c. Delete 6.2.5.3.2.3.c "Pressurizer Relief Tank Subcompartment" and insert the words into 6.2.5.3.2.4.a.

Consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

Delete Figure and replace the title with "Deleted." Consistent with the revised 10CFR50.44 and TSTF 447. (SMF-EVAL-2004-002063-03)

LDCR-SA-2006-10, EVAL-2005-003364-03 (JDS):

Appendix 1A(B) RG 1.82 is revised to show conformance for new sump strainers. See EVAL-2005-003364-16 for the comparison of the old and new designs to the Regulatory Guide.

Updates the FSAR for Modificartions to the plant in response to GSI-191 including License Amendment 129 [see SMF-2005-001869]

Table 3.9B-10 is revised to show the HV-4758/4759 are now butterfly valves.

Updates the FSAR for Modificartions to the plant in response to GSI-191 including License Amendment 129 [see SMF-2005-001869]

LDCR-SA-2006-10, EVAL-2005-003364-03 (JDS) (continued):

Section 6.2.2.2.1 is revised to describe the new sump strainer design and update the outdated description of emergency sump antivortex design found in FSAR Section 6.2.2.2.1 [SMF-2006-003988 issue].

Updates the FSAR for Modificartions to the plant in response to GSI-191 including License Amendment 129 [see SMF-2005-001869]

Section 6.2.2.3.3 is revised to describe the new sump strainer design and add the refueling cavity drain modifications.

Updates the FSAR for Modificartions to the plant in response to GSI-191 including License Amendment 129 [see SMF-2005-001869]

Section 6.2.2.3.4 is revised to correct the NPSH description based on ME-CA-0232-5046 R0 which is the basis for Figure 6.2.2-2.

Updates the FSAR for Modificartions to the plant in response to GSI-191 including License Amendment 129 [see SMF-2005-001869]

Section 6.2.2.5 is revised to describe the new RWST setpoint volumes. The containment water level instrument descritption is clarified to match the ref.d figures inlieu of the conrol board indicators.

Updates the FSAR for Modificartions to the plant in response to GSI-191 including License Amendment 129 [see SMF-2005-001869]

Figure 6.2.2-3 is revised and Figure 6.2.2-3A added to show the new sump strainer design.

Updates the FSAR for Modificartions to the plant in response to GSI-191 including License Amendment 129 [see SMF-2005-001869]

Figure 6.2.2-4 is revised to show the new refueling cavity drain strainers and debris screens.

Updates the FSAR for Modificartions to the plant in response to GSI-191 including License Amendment 129 [see SMF-2005-001869]

Figure 6.2.2-5 is revised to show the removal of the pipe reducer in the refueling cavity drains.

Updates the FSAR for Modificartions to the plant in response to GSI-191 including License Amendment 129 [see SMF-2005-001869]

LDCR-SA-2006-10, EVAL-2005-003364-03 (JDS) (continued):

Section 6.3.2.8 is revised to reflect the new RWSTsetpoints and the new emergency strainer design. Typographical errors in valves tag numbers are corrected. Operator reset of SI is also clarified.

Updates the FSAR for Modificartions to the plant in response to GSI-191 including License Amendment 129 [see SMF-2005-001869]

Table 6.3-7 is revised to reflect change in EOS-1.3 to start spray switchover after the Empty alarm based on ME(B)-389 R10.

Updates the FSAR for Modificartions to the plant in response to GSI-191 including License Amendment 129 [see SMF-2005-001869]

Table 6.3-11 is revised to reflect change in the RWSToutflow analysis and ME(B)-389 R10 based on the above modifications.

Updates the FSAR for Modificartions to the plant in response to GSI-191 including License Amendment 129 [see SMF-2005-001869]

Section 6.5.2.3.2 is revised to reflect the change in pH due to the RWST setpoint changes.

Section 6.5.2.2.1 is revised to clarify CAT isolation valves and vacuum breakers. [ACTN-SMF-2006-004073-01 and ACTN-SMF-2006-004097-01]

Updates the FSAR for Modificartions to the plant in response to GSI-191 including License Amendment 129 [see SMF-2005-001869]

Table 6.5-4 is revised to clarify CAT isolation valves and vacuum breakers. [ACTN-SMF-2006-004073-01 and ACTN-SMF-2006-004097-01]

Updates the FSAR for Modificartions to the plant in response to GSI-191 including License Amendment 129 [see SMF-2005-001869]

Section 7.6.5 is revised to show the instrument alarm uncertainty for new transmitters (changed from 2.5% to 2.3%).

Updates the FSAR for Modificartions to the plant in response to GSI-191 including License Amendment 129 [see SMF-2005-001869]

Section 6.5.2.5.3 is revised to reflect some valves are motor and air operated.

Updates the FSAR for Modificartions to the plant in response to GSI-191 including License Amendment 129 [see SMF-2005-001869]

LDCR-SA-2006-10, EVAL-2005-003364-03 (JDS) (continued):

Table 17A-1 is revised to add the new strainers and debris screens.

Updates the FSAR for Modificartions to the plant in response to GSI-191 including License Amendment 129 [see SMF-2005-001869]

LDCR-SA-2006-31, EVAL-2006-001521-01 (JDS):

The sentence "The interlocks are redundant and can withstand a single failure." is being removed. This interlock is not redundant for system operation in normal mode, however, it satisfies the single failure criteria by being fail-safe rather than redundant. In addition, there is a manual override switch located on the fuel transfer system control panel. In case of mechanical failure of the toggle switch, this override feature can be utilized under administrative control. Therefore, redundancy in the upender clear interlocks is not required.

LDCR-SA-2007-19, EVAL-2001-002201-21 (JDS):

This type of insulation was not utilized and was not described in the insulation specification. In accordance with specification CPES-M-2012 Section 3.5.2 M -

Anti-sweat insulation used inside containment shall

1. be low to medium density fiberglass (e.g. < 8 lb/ft3)

2. not employ a vapor barrier, and

3. be stainless steel jacketed.

LDCR-SA-2007-23, EVAL-2007-002718-02 (GLM):

This proposed change is to add Design Basis Document, DBD-ME-006, to Chapter 1, Section 1.6, Table 1.6-1, DOCUMENTS INCORPORATED BY REFEFENCE.

DBD-ME-006, Attachment 1 captures the final response to NUREG-0612 and GL 81-07 as provided by TXX-3659. Documented in DBD-ME-006 are additional correspondence between the licensee and the NRC occurred after TXX-3659 was issued. This correspondence, including that from the NRC, form the basis for DBD-ME-006 content. By adding DBD-ME-006 to Table1.6-1, information that was provided by TXX-3659 to include subsequent correspondence with the NRC for heavy load controls (parameter values and assumptions, such as lift height, load weight and medium present under the load) would result in information describing the heavy load controls program that would normally be required in the FSAR (by the use of the Incorporated by Reference method). Any changes to the described heavy loads control program (changes to the DBD) have been and will be evaluated per the requirements of design change control process, as

LDCR-SA-2007-23, EVAL-2007-002718-02 (GLM) (continued):

well as 10CFR50.59 process. The original responses were provided by TXX-3659 [7.2.8]. DBD-ME-006 is maintained current under 10CFR50.59. By updating Table 1.6-1 to include DBD-ME-006 as incorporated by reference, and changing reference 17 to DBD-ME-006 (with historical listing of TXX-3659), information supporting the necessary details for FSAR content will be complete. This change has not affected on existing commitments. By implementation of this proposed change, the stated Regulatory Expections from RIS 2005-025 Supplement 1 will have been met.

Revise Section 9.1.4, Reference 17, to be DBD-ME-006 (with TXX-3659 being referenced for historical purposes).

DBD-ME-006, Attachment 1 captures the final response to NUREG-0612 and GL 81-07 as provided by TXX-3659. Documented in DBD-ME-006 are additional correspondence between the licensee and the NRC occurred after TXX-3659 was issued. This correspondence, including that from the NRC, form the basis for DBD-ME-006 content. By adding DBD-ME-006 to Table1.6-1, information that was provided by TXX-3659 to include subsequent correspondence with the NRC for heavy load controls (parameter values and assumptions, such as lift height, load weight and medium present under the load) would result in information describing the heavy load controls program that would normally be required in the FSAR (by the use of the Incorporated by Reference method). Any changes to the described heavy loads control program (changes to the DBD) have been and will be evaluated per the requirements of design change control process, as well as 10CFR50.59 process. The original responses were provided by TXX-3659 [7.2.8]. DBD-ME-006 is maintained current under 10CFR50.59. By updating Table 1.6-1 to include DBD-ME-006 as incorporated by reference, and changing reference 17 to DBD-ME-006 (with historical listing of TXX-3659), information supporting the necessary details for FSAR content will be complete. This change has not affected on existing commitments. By implementation of this proposed change, the stated Regulatory Expections from RIS 2005-025 Supplement 1 will have been met.

LDCR-SA-2007-22, EVAL-2004-002882-07 (JDS):

RG 1.54 description is revised to describe the revised program from Non-safety to Service Level I and the applicable standards. This is an administrative update of the FSAR to reflect an upgrade to the Protective Coatings Program for inside containment. Coatings do not have safety function per se and are not Basic Components as defined in 10CFR50.2. They are not subject to 10CFR21. In addition, they are not "Safety Related" Structures, Systems, or Components as defined in 10CFR50.2. However, coatings are subject to applicable portions of 10CFR50, Appendix B via GDC-1 because their failure has the potential to be detrimental to Safety Related Structures, Systems, and Components. This is most similar to non-seismic items (seismic category II equipment). The CPNPP quality assurance program for such items is covered by Appendix D of the QA Manual. See DBD-ME-028 for additional information on classification of SSCs. [Also note that this change is consistent with ONE 97-1016, Applicability of Appendix B to protective coatings applied to the interior surfaces of safety related components]

LDCR-SA-2007-22, EVAL-2004-002882-07 (JDS) (continued):

Updated description of the Protective Coatings Program for containment. This is an administrative update of the FSAR to reflect an upgrade to the Protective Coatings Program for inside containment.

Updated to remove obsolete information. This is an administrative update of the FSAR to reflect an upgrade to the Protective Coatings Program for inside containment.

Update and clarify description of the quality assurance program (under QA Manual Appendix D). This is an administrative update of the FSAR to reflect an upgrade to the Protective Coatings Program for inside containment. Coatings do not have safety function per se and are not Basic Components as defined in 10CFR50.2. They are not subject to 10CFR21. In addition, they are not "Safety Related" Structures, Systems, or Components as defined in 10CFR50.2. However, coatings are subject to applicable portions of 10CFR50, Appendix B via GDC-1 because their failure has the potential to be detrimental to Safety Related Structures, Systems, and Components. This is most similar to non-seismic items (seismic category II equipment). The CPNPP quality assurance program for such items is covered by Appendix D of the QA Manual. See DBD-ME-028 for additional information on classification of SSCs. [Also note that this change is consistent with ONE 97-1016, Applicability of Appendix B to protective coatings applied to the interior surfaces of safety related components]

LDCR-SA-2006-24, EVAL-2003-000188-03 (JCH):

Table 17A-1

Added notes to the table for manual and extension passive and active valves to provide for the installation of Safety Related / Seismic Category I replacement remote valve stem extensions and gear driven valve operators for the Atmospheric Relief Valves (ARV) upstream isolation block valves, and Seismic Category I supports.

The table lists valve operator types. Clarifying UFSAR Table 17A-1 to describe the requirements for Active valve manual and extension stem operator quality attributes and Passive valve manual and extension stem operator quality attributes is acceptable based on the different quality requirement attributes for active and passive components. This clarification also maintains consistency between the table requirements for safety related valves and the referenced Note 79. This clarification is supported by the requirements of DBD-ME-028, Rev. 13, Attachment 19, Table 2.

Table 3.9B-10

Provided editorial clarification of valve/operator type and method of operation descriptions by specifying handwheels or extension stems as appropriate

LDCR-SA-2006-34, EVAL-2003-002117-03 (JCH):

Section 10.4.3.1-Design Basis-2. Feedwater Pump Turbine Seals

Delete "The feedwater pump turbine is self-sealing at loads above approximately half of the rated load on the turbine."

Section 10.4.3.2-System Description-1. Normal Operation Conditions-b. Feedwater Pump Turbine Steam Seals

Delete "during startup of the turbine and during low-power operation."

Justification: The FWPT technical manual shows that the originally supplied design anticipated seal steam would be supplied to the turbine during both start-up and full load operation; therefore, self sealing is not a design attribute of the FWPT's at CPSES. Operations has never seen a self-sealing indication for the feedwater pump turbine in either steam seal supply or dump valve positions. This does not affect the operational capability of the seal system and is congruent with the expectations outlined by the vendor.

LDCR-SA-2007-16, EVAL-2006-002471-02 (RJK):

The values presently listed in Section 5.3.2.2.1 are historic to pre-operational calculations performed IAW Reg Guide 1.99 revision 1 for pre-licensing certification of the reactor vessels. These values were recalculated just prior to Unit 1 and 2 startup using revision 2 of Reg Guide 1.99, but were never updated in the FSAR. These updated values are currently listed in the CPSES PTLR (Table 2-1) and were previously reported to the USNRC via letters TXX-95220 and TXX-97275 in response to Generic Letter 92-01.

LDCR-SA-2007-5, EVAL-2006-003933-05 (JDS):

The Unit 1 Cycle 13 core configuration consists of 88 fresh Westinghouse fuel assemblies (Region 15), 89 once-burned Westinghouse assemblies (88-Region 14 & 1-Region 13), and 16 twice-burned Westinghouse assemblies (Region 13). The single once-burned Region 13 fuel assembly is reloaded from the spent fuel pool. The Region 14/15 Westinghouse fuel assemblies are of the Vantage-Plus with Intermediate Flow Mixing (IFM) grids) and include a thin zirconium oxide coating applied to the bottom seven inches of each fuel rod to provide additional debris fretting protection in this area. Oxide forms naturally on the fuel cladding during normal operation so this coating has no impact on fuel design function. The Region 13 Westinghouse fuel assemblies are also of the Vantage-Plus design, but do not include IFMs or the applied oxide coating but are dimensionally equivalent to the Vantage-Plus design. All fuel assemblies are equipped with the “Small Hole” debris filtering bottom nozzle, an alternate protective grid (P-grid) located just above the bottom nozzle to trap any debris making it through the bottom nozzle, and long solid end plugs. The pressure drop through the Vantage-Plus (without IFMs) assemblies is slightly lower than that through the co-resident fresh Vantage-Plus / IFM assemblies while the heat transfer characteristics are improved by the IFMs. The effects of the mixed core on the thermal hydraulic response are considered.

LDCR-SA-2007-5, EVAL-2006-003933-05 (JDS) (continued):

All the Westinghouse assemblies use ZIRLO (as opposed to Zircaloy-4) for the fuel rod cladding, guide tubes and assembly mid-span grids. In addition, integrated fuel burnable absorbers (IFBAs) and discrete wet annular burnable absorbers (WABAs) are used to shape the power distribution and achieve a desirable moderator temperature coefficient.

The thermal-hydraulic and neutronic responses of the Unit 1 Cycle 13 reload core configuration potentially affect the design functions of many plant components and systems. The acceptability of the Cycle 13 reload core configuration is based on meeting the event acceptance criteria in FSAR Sections 3.6B, 4.2, 4.3, 4.4, 6.2, 6.3, and all of FSAR Chapter 15.

The neutronic design criteria of the Cycle 13 reload core configuration continue to be met. The thermal-hydraulic design criteria of the Cycle 13 reload core configuration continue to be met.

The adequacy of the systems required to mitigate or prevent accidents, shutdown the plant and maintain the plant in a safe shutdown condition is demonstrated in the analyses presented in FSAR Chapter 15 and summarized in the Cycle 13 update of FSAR Appendix 4A. The relevant event acceptance criteria include compliance with the DNBR and peak RCS and steamline pressure acceptance criteria for ANS Condition II transients and acceptable radiological consequences for ANS Condition III and IV accidents. Relevant event acceptance criteria continue to be met with the current cycle-specific reactor physics parameters.

LDCR-SA-2007-21, EVAL-2006-004074-01 (GLM):

Remove the paragraph in FSAR Section 9.2.1.2.1 which states that the Circulating Water Bleed line is used as a continuous makeup for SSI and add a note to Section 9.2.1.2.1 which states that additional details can be found in Section 9.2.5.2.

As stated in FSAR Section 9.2.5.1 the function of the ultimate heat sink is to dissipate heat rejected from the station service water system during post accident shutdown and normal cooldown conditions. The Safe Shutdown Impoundment (SSI) is a part of the Ultimate Heat Sink. The level of water in the SSI is maintained through an equalization canal between the Squaw Creek Reservoir (SCR) and the SSI as described in the FSAR in Sections 9.2.1.2.1 and 9.2.5.2. The equalization canal between the SSI and Squaw Creek Reservoir is current the normal source for makeup to the SSI as indicated by the Operations procedures SOP-310A and SOP-310B.

A bleed line is provided from the Circulating Water System, at the intake structure, to the Service Water Intake Structure pump suction pit. The FSAR indicates that when operated the circulating water bleed-off ensures continuous makeup to the SSI and provides circulation to prevent excessive dissolved solids concentration in the SSI. Based on the operations procedures (SOP-310A and SOP-310B) above this is not

LDCR-SA-2007-21, EVAL-2006-004074-01 (GLM) (continued):

currently the way that the system is operated. The procedure indicates that the bleed line is normally closed. This is supported by the valve line-up attachment to the procedures which indicates that valve 1CW-0019 is normally closed.

IOR No. 89-64 was written to address environmental regulations which require that the discharge from the Safe Shutdown Impoundment to the Squaw Creek Reservoir be monitored. This includes the flow from the Circulating Water Bleed line. The IOR states that valve 1CW-0019 is intended to remain closed during plant operation until the plasitc is removed from the bleed line. Based on the changes made by IOR No. 89-64 and CPSES Procedure Change Form for SOP-310A, Rev. 5, the method of operation was revised in 1990. The IOR states that the flow Circulating Water System to the Safe Shutdown Impoundment via the bleed line be closed using valve 1CW-0019. In lieu of using the Circulating Water bleed line as the normal makeup, the equalization canal between the SSI and Squaw Creek Reservoir is used as the normal source for make-up to the SSI as indicated by the Operations procedures SOP-310A and SOP-310B.

Delete the last paragraph in FSAR Section 9.2.5.2 and add a new paragraph describing the Circulating Water Bleed line and its current operation.

As stated in FSAR Section 9.2.5.1 the function of the ultimate heat sink is to dissipate heat rejected from the station service water system during post accident shutdown and normal cooldown conditions. The Safe Shutdown Impoundment (SSI) is a part of the Ultimate Heat Sink. The level of water in the SSI is maintained through an equalization canal between the Squaw Creek Reservoir (SCR) and the SSI as described in the FSAR in Sections 9.2.1.2.1 and 9.2.5.2. The equalization canal between the SSI and Squaw Creek Reservoir is current the normal source for makeup to the SSI as indicated by the Operations procedures SOP-310A and SOP-310B.

A bleed line is provided from the Circulating Water System, at the intake structure, to the Service Water Intake Structure pump suction pit. The FSAR indicates that when operated the circulating water bleed-off ensures continuous makeup to the SSI and provides circulation to prevent excessive dissolved solids concentration in the SSI. Based on the operations procedures (SOP-310A and SOP-310B) above this is not currently the way that the system is operated. The procedure indicates that the bleed line is normally closed. This is supported by the valve line-up attachment to the procedures which indicates that valve 1CW-0019 is normally closed.

IOR No. 89-64 was written to address environmental regulations which require that the discharge from the Safe Shutdown Impoundment to the Squaw Creek Reservoir be monitored. This includes the flow from the Circulating Water Bleed line. The IOR states that valve 1CW-0019 is intended to remain closed during plant operation until the plasitc is removed from the bleed line. Based on the changes made by IOR No. 89-64 and CPSES Procedure Change Form for SOP-310A, Rev. 5, the method of operation was revised in 1990. The IOR states that the flow Circulating Water System to the Safe Shutdown Impoundment via the bleed line be closed using valve 1CW-0019. In lieu of

LDCR-SA-2007-21, EVAL-2006-004074-01 (GLM) (continued):

using the Circulating Water bleed line as the normal makeup, the equalization canal between the SSI and Squaw Creek Reservoir is used as the normal source for make-up to the SSI as indicated by the Operations procedures SOP-310A and SOP-310B.

In Section 9.2.5.3, under "2. Hydraulic Performance," delete the word "creates" and replace with "can be used if required."

As stated in FSAR Section 9.2.5.1 the function of the ultimate heat sink is to dissipate heat rejected from the station service water system during post accident shutdown and normal cooldown conditions. The Safe Shutdown Impoundment (SSI) is a part of the Ultimate Heat Sink. The level of water in the SSI is maintained through an equalization canal between the Squaw Creek Reservoir (SCR) and the SSI as described in the FSAR in Sections 9.2.1.2.1 and 9.2.5.2. The equalization canal between the SSI and Squaw Creek Reservoir is current the normal source for makeup to the SSI as indicated by the Operations procedures SOP-310A and SOP-310B.

A bleed line is provided from the Circulating Water System, at the intake structure, to the Service Water Intake Structure pump suction pit. The FSAR indicates that when operated the circulating water bleed-off ensures continuous makeup to the SSI and provides circulation to prevent excessive dissolved solids concentration in the SSI. Based on the operations procedures (SOP-310A and SOP-310B) above this is not currently the way that the system is operated. The procedure indicates that the bleed line is normally closed. This is supported by the valve line-up attachment to the procedures which indicates that valve 1CW-0019 is normally closed.

IOR No. 89-64 was written to address environmental regulations which require that the discharge from the Safe Shutdown Impoundment to the Squaw Creek Reservoir be monitored. This includes the flow from the Circulating Water Bleed line. The IOR states that valve 1CW-0019 is intended to remain closed during plant operation until the plasitc is removed from the bleed line. Based on the changes made by IOR No. 89-64 and CPSES Procedure Change Form for SOP-310A, Rev. 5, the method of operation was revised in 1990. The IOR states that the flow Circulating Water System to the Safe Shutdown Impoundment via the bleed line be closed using valve 1CW-0019. In lieu of using the Circulating Water bleed line as the normal makeup, the equalization canal between the SSI and Squaw Creek Reservoir is used as the normal source for make-up to the SSI as indicated by the Operations procedures SOP-310A and SOP-310B.

FSAR Amendment 101, Supplement b

LDCR-SA-2007-11, EVAL-2005-001957-23 (JDS):

Update list of Tables to match revised Tables.

Update list of Figures to Match revised or deleted Figures.

Sections 6.2.1.1.3.1.1 and 6.2.1.1.3.1.2 were modified due to the methodology change and Steam Generator replacement which resulted in differences in the analysis results for the two units.

Section 6.2.1.1.3.2 was modified to reflect the changes in the Figures and the RSGs.

Section 6.2.1.1.3.7 is modified to reflect the changes in the Tables and the RSGs.

Section 6.2.1.2.1 is modified to reflect the changes in the methodology and RSGs. Section 6.2.1.2.2 is modified to reflect the changes in the Figures.Section 6.2.1.2.3 is modified to reflect the changes in the methodology and the addition of the RSGs for Unit 1. Also, many of the Figures and Tables described in this Section were determined to be no longer required, and therefore removed.

Section 6.2.1.3 was re-written due to the methodology update.

Sections 6.2.1.4.1 and 6.2.1.4.2 is modified to reflect the changes or deletions in the Tables

Section 6.2.1.4.9 is deleted due to the deletion of the Tables described in this Section.

Section 6.2.1.5.6 is modified to reflect the changes in the Tables

Section 6.2.2.3.2 is modified to reflect the changes in the Tables

6.2.1-2A was replaced with 6.2.1-2A.1 and 6.2.1-2A.2 due to differences between Units 1 and 2 as a result of Unit 1 Steam Generator Replacement.

6.2.1-2B was replaced with 6.2.1-2B.1 and 6.2.1-2B.2 due to differences between Units 1 and 2 as a result of Unit 1 Steam Generator Replacement.

Tables 6.2.1-3 and -3A were deleted as the information contained in them is not required. The Mass and Energy Release Data for both LOCA and SLB for Unit 2 is unchanged. However, for Unit 1, the mass and energy release data for both LOCA and SLB have been modified. For LOCA, the change in the M&E release data is due to both the RSGs and a methodology change. For SLB, the change in the M&E release data is due solely to the RSGs.

LDCR-SA-2007-11, EVAL-2005-001957-23 (JDS) (continued):

Tables 6.2.1-4, -4A, and -4B were deleted as the information contained in them is not required. The Mass and Energy Release Data for both LOCA and SLB for Unit 2 is unchanged. However, for Unit 1, the mass and energy release data for both LOCA and SLB have been modified. For LOCA, the change in the M&E release data is due to both the RSGs and a methodology change. For SLB, the change in the M&E release data is due solely to the RSGs.

Table 6.2.1-15 was deleted as the information contained in it is not required. The Mass and Energy Release Data for both LOCA and SLB for Unit 2 is unchanged. However, for Unit 1, the mass and energy release data for both LOCA and SLB have been modified. For LOCA, the change in the M&E release data is due to both the RSGs and a methodology change. For SLB, the change in the M&E release data is due solely to the RSGs.

6.2.1-9 was replaced with 6.2.1-9A and 6.2.1-9B due to differences between Units 1 and 2 as a result of Unit 1 Steam Generator Replacement.

6.2.1-10 was replaced with 6.2.1-10A and 6.2.1-10B due to differences between Units 1 and 2 as a result of Unit 1 Steam Generator Replacement.

Table 6.2.1-21 was deleted as the information contained in it is not required. The Mass and Energy Release Data for both LOCA and SLB for Unit 2 is unchanged. However, for Unit 1, the mass and energy release data for both LOCA and SLB have been modified. For LOCA, the change in the M&E release data is due to both the RSGs and a methodology change. For SLB, the change in the M&E release data is due solely to the RSGs.

Table 6.2.1-26 was deleted as the information contained in it is not required. The Mass and Energy Release Data for both LOCA and SLB for Unit 2 is unchanged. However, for Unit 1, the mass and energy release data for both LOCA and SLB have been modified. For LOCA, the change in the M&E release data is due to both the RSGs and a methodology change. For SLB, the change in the M&E release data is due solely to the RSGs.

Table 6.2.1-29 was deleted as the information contained in it is not required. The Mass and Energy Release Data for both LOCA and SLB for Unit 2 is unchanged. However, for Unit 1, the mass and energy release data for both LOCA and SLB have been modified. For LOCA, the change in the M&E release data is due to both the RSGs and a methodology change. For SLB, the change in the M&E release data is due solely to the RSGs.

LDCR-SA-2007-11, EVAL-2005-001957-23 (JDS) (continued):

Table 6.2.1-30 was deleted as the information contained in it is not required. The Mass and Energy Release Data for both LOCA and SLB for Unit 2 is unchanged. However, for Unit 1, the mass and energy release data for both LOCA and SLB have been modified. For LOCA, the change in the M&E release data is due to both the RSGs and a methodology change. For SLB, the change in the M&E release data is due solely to the RSGs.

Tables 6.2.1-37 through -49 were deleted as the information contained in them is not required. The Mass and Energy Release Data for both LOCA and SLB for Unit 2 is unchanged. However, for Unit 1, the mass and energy release data for both LOCA and SLB have been modified. For LOCA, the change in the M&E release data is due to both the RSGs and a methodology change. For SLB, the change in the M&E release data is due solely to the RSGs.

Table 6.2.1-50 was deleted as the information contained in it is not required. The Mass and Energy Release Data for both LOCA and SLB for Unit 2 is unchanged. However, for Unit 1, the mass and energy release data for both LOCA and SLB have been modified. For LOCA, the change in the M&E release data is due to both the RSGs and a methodology change. For SLB, the change in the M&E release data is due solely to the RSGs.

Table 6.2.1-50A was deleted as the information contained in it is not required. The Mass and Energy Release Data for both LOCA and SLB for Unit 2 is unchanged. However, for Unit 1, the mass and energy release data for both LOCA and SLB have been modified. For LOCA, the change in the M&E release data is due to both the RSGs and a methodology change. For SLB, the change in the M&E release data is due solely to the RSGs.

Table 6.2.1-51 through -56 were deleted as the information contained in them is not required. The Mass and Energy Release Data for both LOCA and SLB for Unit 2 is unchanged. However, for Unit 1, the mass and energy release data for both LOCA and SLB have been modified. For LOCA, the change in the M&E release data is due to both the RSGs and a methodology change. For SLB, the change in the M&E release data is due solely to the RSGs.

Table 6.2.1-58 through -60 were deleted as the information contained in ithem is not required. The Mass and Energy Release Data for both LOCA and SLB for Unit 2 is unchanged. However, for Unit 1, the mass and energy release data for both LOCA and SLB have been modified. For LOCA, the change in the M&E release data is due to both the RSGs and a methodology change. For SLB, the change in the M&E release data is due solely to the RSGs.

LDCR-SA-2007-11, EVAL-2005-001957-23 (JDS) (continued):

Table 6.2.1-64 through -69 were deleted as the information contained in them is not required. The Mass and Energy Release Data for both LOCA and SLB for Unit 2 is unchanged. However, for Unit 1, the mass and energy release data for both LOCA and SLB have been modified. For LOCA, the change in the M&E release data is due to both the RSGs and a methodology change. For SLB, the change in the M&E release data is due solely to the RSGs.

Table 6.2.1-77 was deleted as the information contained in it is not required. The Mass and Energy Release Data for both LOCA and SLB for Unit 2 is unchanged. However, for Unit 1, the mass and energy release data for both LOCA and SLB have been modified. For LOCA, the change in the M&E release data is due to both the RSGs and a methodology change. For SLB, the change in the M&E release data is due solely to the RSGs.

Table 6.2.1-91 was deleted as the information contained in it is not required. The Mass and Energy Release Data for both LOCA and SLB for Unit 2 is unchanged. However, for Unit 1, the mass and energy release data for both LOCA and SLB have been modified. For LOCA, the change in the M&E release data is due to both the RSGs and a methodology change. For SLB, the change in the M&E release data is due solely to the RSGs.

Table 6.2.1-93 was deleted as the information contained in it is not required. The Mass and Energy Release Data for both LOCA and SLB for Unit 2 is unchanged. However, for Unit 1, the mass and energy release data for both LOCA and SLB have been modified. For LOCA, the change in the M&E release data is due to both the RSGs and a methodology change. For SLB, the change in the M&E release data is due solely to the RSGs.

Table 6.2.1-95 through -104 were deleted as the information contained in them is not required. The Mass and Energy Release Data for both LOCA and SLB for Unit 2 is unchanged. However, for Unit 1, the mass and energy release data for both LOCA and SLB have been modified. For LOCA, the change in the M&E release data is due to both the RSGs and a methodology change. For SLB, the change in the M&E release data is due solely to the RSGs.

Figures 6.2.1-1 through -3 were deleted due to the revised analysis. The Mass and Energy Release Data for both LOCA and SLB for Unit 2 is unchanged. However, for Unit 1, the mass and energy release data for both LOCA and SLB have been modified. For LOCA, the change in the M&E release data is due to both the RSGs and a methodology change. For SLB, the change in the M&E release data is due solely to the RSGs.

Figures 6.2.1-9 through -16 were modified due to the revised analysis. The Mass and Energy Release Data for both LOCA and SLB for Unit 2 is unchanged. However, for Unit 1, the mass and energy release data for both LOCA and SLB have been modified. For LOCA, the change in the M&E release data is due to both the RSGs and a methodology change. For SLB, the change in the M&E release data is due solely to the RSGs.

LDCR-SA-2007-11, EVAL-2005-001957-23 (JDS) (continued):

Figure 6.2.1-20 was deleted due to the revised analysis. The Mass and Energy Release Data for both LOCA and SLB for Unit 2 is unchanged. However, for Unit 1, the mass and energy release data for both LOCA and SLB have been modified. For LOCA, the change in the M&E release data is due to both the RSGs and a methodology change. For SLB, the change in the M&E release data is due solely to the RSGs.

Figures 6.2.1-30 through -45 were deleted due to the revised analysis. The Mass and Energy Release Data for both LOCA and SLB for Unit 2 is unchanged. However, for Unit 1, the mass and energy release data for both LOCA and SLB have been modified. For LOCA, the change in the M&E release data is due to both the RSGs and a methodology change. For SLB, the change in the M&E release data is due solely to the RSGs.

Figures 6.2.1-49 through -52 were deleted due to the revised analysis. The Mass and Energy Release Data for both LOCA and SLB for Unit 2 is unchanged. However, for Unit 1, the mass and energy release data for both LOCA and SLB have been modified. For LOCA, the change in the M&E release data is due to both the RSGs and a methodology change. For SLB, the change in the M&E release data is due solely to the RSGs.

Figures 6.2.1-54 through -56 were deleted due to the revised analysis. The Mass and Energy Release Data for both LOCA and SLB for Unit 2 is unchanged. However, for Unit 1, the mass and energy release data for both LOCA and SLB have been modified. For LOCA, the change in the M&E release data is due to both the RSGs and a methodology change. For SLB, the change in the M&E release data is due solely to the RSGs.

Figures 6.2.1-58 through -70 were deleted due to the revised analysis. The Mass and Energy Release Data for both LOCA and SLB for Unit 2 is unchanged. However, for Unit 1, the mass and energy release data for both LOCA and SLB have been modified. For LOCA, the change in the M&E release data is due to both the RSGs and a methodology change. For SLB, the change in the M&E release data is due solely to the RSGs.

FSAR Amendment 102

LDCR-SA-2007-18, EVAL-2003-000167-04 (RJK):

Neutron dosimetry sensors used to monitor neutron exposure for continued surveillance of reactor vessel integrity were installed in CPNPP unit 1 reactor cavity annulus per FDA 2003-000167-01 and the FSAR was updated per LDCR SA-2003-059. This LDCR was required to document that the neutron dosimetry sensors are also now installed in the unit 2 reactor cavity annulus and FSAR section 5.3.1.6.2 now applies to both units.

LDCR-SA-2007-20, EVAL-2006-000629-04 (TJEW):

In 9.1.3.1.1.1, the first sentence of the second paragraph reads, "The spent fuel pool bulk water temperatures are maintained at less than 150EF for normal operation based on decay heat generation from a normal full core offload at 7days after shutdown, plus decay heat from the opposite unit’s last refueling discharge plus decay heat from fuel assemblies from a maximum number of previous refuelings in both pools."

1.) In the 150EF, replace the "E" with a degree symbol, and

2.) Change "7 days" to "125 hours".

In 9.1.3.1.1.1, the third and fourth sentence in the fourth paragraph reads, "The start of the second outage is conservatively assumed to begin 45 days after the first. A normal full core offload is conservatively assumed to start at 100 hours after the reactor is subcritical and complete at 168 hours."

1.) Change "45 days" to "4 months",

2.) Change "100" hours to "75" hours, and

3.) Change "168" hours to "125" hours.

4.) In the last paragraph of 9.1.3.1.1.1, for the term "140EF" replace the "E" with a degree sign.

In 9.1.3.1.1.3, the second paragraph reads, "The spent fuel pool water temperatures are maintained at less than 212°F for two loop operation based on an emergency core offload 150 hours after shutdown, plus the most recent refueling discharge 36 days after shutdown, plus the opposite unit’s previous refueling discharge 66 days after shutdown, plus decay heat from a maximum number of previous refuelings in both pools."

1.) Change "150" hours to "125" hours,

2.) Change "36 days after" to "31 days prior to", and

3.) Change "66 days after" to "5 months prior to"

1.) On Table 9.1-1, under Parameters,

LDCR-SA-2007-20, EVAL-2006-000629-04 (TJEW) (continued):

a.) delete the row "Numbr of fuel assemblies stored" and

b.)change the exponent of Decay Heat Producted from "10 to the 5" to 10 to the 6"

2.) On the same row of Decay heat produced, make the following changes:

Under MAX. DESIGN

a.) MAX POOL from 50.7 to 52.0

b.) MIN POOL from 5.55 to 9.09

Under MAX. SUMMER DESIGN

a.) MAX POOL from 21.3 to 23.28

b.) MIN POOL from 5.55 to 6.08

Under ABNORMAL MAX. DESIGN

a.) MAX POOL from 56.5 to 62.92

b.) MIN POOL from 6.0 to 6.6

3.) For the parameter Time to boil, change MAX SUMMER DESIGN, MAX POOL from >7 to >3

4.) Under the "NOTES" section,

a.) Replace the words in the note with “Deleted”, and

b.1) in note 3, replace the words "assumes most resent spent fuel discharges are" with the word “loads”, and

b.2) delete "to" after the words "MAX Pool"

On Table 12.2-24, "DESIGN PARAMETERS FOR POST-ACCIDENT DOSE EVALUATIONS"

1.) Under Gap activity-release

a.) Replace "Noble gases other than Kr-85 0.1" with "I-131 0.08"

b.) Change the value of Kr-85 from "0.3" to "0.10"

FSAR Amendment 102

LDCR-SA-2007-20, EVAL-2006-000629-04 (TJEW) (continued):

c.) Replace "Iodines other than I-127 and I-129 0.1" with "Other Iodines and Noble Gases 0.05"

2.) Change the Decay interval between reactor shutdown and commencement of refueling operations (hours) from "100" to "75"

In 15.7.4.2.1, change "100 hr" to "75 hours"

In 15.7.4.3.1.1, change "100 hr" to "75 hours"

1.) In 15.7.4.3.1.3, change "100" hours to "75" hours

2.) In the last paragraph of 15.7.4.3.1, change "0.087" rem to "0.090" rem

Revise Table 15.7-6, NOBLE GAS AND IODINE ACTIVITIES RELEASED FROM DAMAGED FUEL RODS AS A RESULT OF A FUEL HANDLING ACCIDENT as follows:

1.) Revise Kr-85 from "8.62" to "9.66"

2.) Add "Kr-85m" to be "9.62E-02" curries released

3.) Add "Kr-88" to be "3.05E-04" curries released

4.)Revise Xe-131m from "3.01" to "4.57"

5.) Revise Xe-133m from "5.56" to "1.52"

6.) Revise Xe-133 from "6.93" to "6.88"

7.) Revise Xe-135m from "3.61" to "5.04E+00"

8.) Revise Xe-135 from "1.20" to "7.05"

9.) No revision to I-131

10.) Revise I-132 from "2.87" from to 3.25

11.) Revise I-133 from "3.47" to "7.44"

12.) Revise I-135 from "2.36" to "3.07E+01"

13.) Revise a.3 from "100" hours to "75" hours

On Table 15.7-8, PARAMETERS FOR POSTULATED FUEL HANDLING ACCIDENT ANALYSIS, change

LDCR-SA-2007-20, EVAL-2006-000629-04 (TJEW) (continued):

1.) In 1.a, Power Level (MWt) from "3565" to "3694" and

2.) In 4.c, Doses, change "0.087" rem to "0.090" rem

LDCR-SA-2006-41, EVAL-2006-003110-02 (CBC):

In paragraph 6.2.6.4, item 1, revise the first by inserting an "s" at the end of "exception" and deleting the numeral "1" at the end of "5.5.16.a.1". The new sentence will read as follows:

"Containment integrated leakage-rate test (Type A) are performed at least once per 48 months with possible extension to 10 yr. intervals based upon acceptable performance history as determined in accordance with NEI 94-01 and Reg. Guide 1.163, as modified by the exceptions in Technical Specification 5.5.16.a."

FSAR Section 6.2.6.4 is updated by eliminating the concrete containment inspections required by Appendix J, Option B and taking credit for the concrete containment inspections performed under the IWL and IWE of the ASME program (which CPSES is already committed to). The FSAR is updated to be consistent with changes to TS 5.5.16 approved by the NRC in License Amendment 141.

LDCR-SA-2006-23, EVAL-2005-004439-02 (JCH):

Page 9.5-71: add "wireless intercom system" to the types of communication systems listed

Justification: The Refuleing and Emergency sound Powered Loops have been replaced by a wireless intercom with radio backup and emergency communications is supplied by the Inplant Radio System with Gaitronics backup.

Delete references to refueling and emergency sound powered loops

Justification: The Refuleing and Emergency sound Powered Loops have been replaced by a wireless intercom with radio backup and emergency communications is supplied by the Inplant Radio System with Gaitronics backup.

Added new section 9.5.2.2.8 which discusses the wireless intercom system and renumbered subsequent sections.

Justification: The Refuleing and Emergency sound Powered Loops have been replaced by a wireless intercom with radio backup and emergency communications is supplied by the Inplant Radio System with Gaitronics backup.

Added paragraph that power to the wireless intercom system is provided by plant support power and each headset has an individual battery supply.

LDCR-SA-2006-23, EVAL-2005-004439-02 (JCH) (continued):

Justification: The Refuleing and Emergency sound Powered Loops have been replaced by a wireless intercom with radio backup and emergency communications is supplied by the Inplant Radio System with Gaitronics backup.

Deleted reference to testing of refueling and emergency sound powered loops

Justification: The Refuleing and Emergency sound Powered Loops have been replaced by a wireless intercom with radio backup and emergency communications is supplied by the Inplant Radio System with Gaitronics backup.

LDCR-SA-2005-29, EVAL-2005-003364-07 (JDS):

Suction pressure accident monitoring is added for the RHR and Containment Spray pumps. Table 7.5-7B is updated. Flow Diagrams 5.4-6 and 6.2.2-1 are updated as detailed in FDA-2005-003364-08 and -18. These modifications will be implemented at power in 2007.

Suction pressure accident monitoring is added for the RHR and Containment Spray pumps.These components have been identified in Attachment 1 of TXX-05162 as requiring monitoring for system performance. The are utilized as a key variable for emergency sump performance. These instruments are not required by Table 2 of RG 1.97 Rev. 2. CPSES utilization is an alternate to narrow range sump level, Type B Category 2. It is classifed as a Type D Category 2 variable because it provides information to indicate the operation of individual safety systems and other systems important to safety. These variables are to help the operator make appropriate decisions in using the individual systems important to safety in mitigating the consequences of an accident.

LDCR-SA-2008-4, EVAL-2007-001435-01 (RJK):

Changes system description to allow use of both CVCS mixed bed demineralizers during RCS cleanup during outages. FDA-2007-001435-01 provides the basis for allowing increased flow during RCS cleanup based upon less than minimal impact on SSCs and radiological consequences due to higher flow rates.

The FSAR is also administratively updated to clarify the maximum letdown flow. DCN 9970 provides the basis for the normal CVCS flow for a nominal 120 gpm design is a maxiumum of 140 gpm based on accuracies of the orifice construction. This flow rate corresponds to a critical input to the radiological consequences in Section 15.6.2.

The FSAR is updated to clarify the maximum letdown flow. DCN 9970 provides the basis for the normal CVCS flow for a nominal 120 gpm design is a maxiumum of 140 gpm based on accuracies of the orifice construction. This flow rate corresponds to a critical input to the radiological consequences in Section 15.6.2.

LDCR-SA-2008-4, EVAL-2007-001435-01 (RJK) (continued):

Section 15.6.2 is administratively corrected to note that the pressure switches are not safety related and may NOT be credited as "the" method of detection.

LDCR-SA-2006-3, EVAL-2001-001214-01 (JCH):

Section 10.2.2.6 Generator

Sectin 10.2.2.6.2 Fire Prevention and Protection

Page 10.2-6: Change the referenced inert gas from "carbon dioxide" to "argon".

Justification: Change of the inert gas used when purging the generator was changed from carbon dioxide to argon due equipment obsolescence, personnel safety and improved outage purging time.

LDCR-SA-2007-2, EVAL-2005-002580-04 (TJEW):

Revise turbine HP & LP stop and control valves test frequency from 12 weeks to 26 weeks. This recommendation was based on a quantitative evaluation on the probability of failure of the overspeed trip and protection system as a function of the turbine stop and control valve test interval. The basic principles of the methodology are the same as those used by Siemens in previous studies which included the CPSES original designs, Grand Gulf, Connecticut Yankee, and Limerick and which have been previously reviewed and accepted by the NRC.

For Table 1.6-1, sheet 2 of 3, replace the 9th Reference which reads:

"'Missile Probability Analysis Methodology for TXU Generation Company, LP, Comanche Peak Units 1 & 2 with Siemens Retrofit Turbines,' CT-27331 (CONFIDENTIAL), Revision No. 3, December 15, 2003"

with the following words,

"TP-03143, "Missile Analysis Methodology for GE Nuclear Steam Turbine Rotors by the SWPC," July 31, 2003."

In Section 3.5.1.3.2,

1.) In the 1st sentence in the 4th paragraph, replace the word "probabiliy" with "probability"

2.) In the 5th paragraph change the Section number from "3.5.1.3.3.1" to "3.5.1.3.3" and delete the words "Unit 1"

In Section 3.5.1.3.3, add "[17]" to the end of the first paragraph.

FSAR Amendment 102

LDCR-SA-2007-2, EVAL-2005-002580-04 (TJEW) (continued):

1.) In section 3.5.1.3.3 on page 3.5-9, replace the words,

"P1 = 3.42E-5 per year for 100,000 hour inspection interval [15]"

with the words,

"P1 = 1.56E-4 at 100,000 hours (inspection interval) for a 26 weeks turbine valve test frequency [15]"

2.) In the last pargrapgh second sentence after "P1" add the following works, "at 100,000 hours inspection interval" and after "the NRC limit of" add the following words, "11.42E-4 when adjusted to 100,000 hours inspection interval verses".

3.) In section 3.5.1.3.4, number 2, change "12" to "26"

4.) In section 3.5.1.3.4 in the last paragraph, change "5x10^-6" to "1.37x10^-5" and

replace References " [5,11,13,][14]" with the following words, "and 26 week turbine valve test interval [15]"

5.) Delete the last sentence of the last paragraph that reads, "CPSES turnine missile analysis is based on a conservative high turbine missile generation probability of 4 x 10^-5 per turbine year."

6.) In section 3.5.1.3.5, replace the following sentence that reads,

"Periodic testing of the stop and control valves is necessary to insure reliability and continuity of service; therefore, valve testing for all nuclear units is recommended with the aid of an automatic turbine tester (ATT) every 12 weeks."

with the following sentence,

"Periodic testing of the stop and control valves is necessary to insure reliability and continuity of service; therefore, valve testing for all nuclear units is recommended with a manual test or with the aid of an automatic turbine tester (ATT) every 26 weeks."

At the end of the first paragraph and at the end of the 17 th of 10.2.3.5, replace Reference [10] with [2].

In the Reference section of 3.5,

1.) replace References 5 with the word "Deleted"

2.) replace References 11, 13 and 14 with the word "Deleted"

LDCR-SA-2007-2, EVAL-2005-002580-04 (TJEW) (continued):

3.) change the revision number of Reference 15 from "4" to "5," change the date from "December 15, 2003" to "January 18, 2007," and delete the VL number.

1.) For Reference 3.5, delete the VL number from Reference 16.

2.) For Reference 3.5, add Reference 17 that will read

"TP-03143, "Missile Analysis Methodology for GE Nuclear Steam Turbine Rotors by the SWPC," July 31, 2003."

In section 10.2.2.1, first paragraph, change "44" to "46."

In section 10.2.2.7.6, number 2, change "12" to "26."

In the 4th paragraph of 10.2.3.6, change "12" to "26."

1.) In the Reference section of 10.2, replace the VL numbers in Reference 1 with "July 1975" and change "46" to "44"

2.) In Reference 2

a.) delete "Allis-Chalmer's Power Systems, Inc.,"

b.) replace "rpm" with "r/min",

c.) replace "46" with "44", and

d.) replace "[VL 04-0051540}" with "October 1975"

3.) In the Reference section of 10.2, replace References 7, 8, and 9 with the word "Deleted"

4.) In the Reference section of 10.2, replace the revision number of Reference 10 from "4" to "5", add "LP" after "Company," change the date from "December 15, 2003" to "January 18, 2007," and delete the VL number.

In the Reference section of 10.2, replace Reference 11 with the words "TP-03143, "Missile Analysis Methodology for GE Nuclear Steam Turbine Rotors by the SWPC," July 31, 2003."

LDCR-SA-2006-25, EVAL-2004-002055-01 (JCH):

Revise the second sentence in paragraph 10.2.2.6 to rep[lace "60 psig" with "psig"

Revise the next to last paragraph in 10.2.2.6.2.1 by replacing "seal oil storage tank" with "Hydrogen Degassing Storage Tank".

LDCR-SA-2006-25, EVAL-2004-002055-01 (JCH) (continued):

Revise the last sentence in the paragraph to clarify that the loop seal is permanently filled.

Revise the last paragraph to state "The seal oil drained from the seal oil tank passes into the Hydrogen Degassing Storage Tank to which the vapor exhauster is also connected. The exhauster creates a slight vacuum in the Hydrogen Degassing StorageTank so that oil saturated with hydrogen is degassed."

In Table 10.4-10, sheet 2 of 3, replace the current a. and b. item entries under "Generator Seal Oil Unit" with the following:

"Air Side Coolers", "2", "1", "113", and "0.65 x 10E6"

Revise the "Maximum Guaranteed Rating" and "Valves Wide Open" values for Hydrogen Pressure from 60 psig to 75 psig.

Revise the "service pressure" values for Hydrogen from "4.2 bar" aand "60 psig" to "5.1 bar" and "75 psig".

LDCR-SA-2008-8, EVAL-2007-002816-02 (RAS):

Revises position titles and organization descriptions to reflect approved titles maintained in EIS and the current CPNPP organizational structure.

LDCR-SA-2008-9, EVAL-2007-002223-01 (RJK):

CP License Amendment 128 changed the limit for identified primary to secondary leakage in TS LCO 3.4.13 to 150 GPD for any SG in each unit. This change removed an existing unit difference and brought the TS LCO into agreement with the standard technical specifications as modified by TSTF-449 R4. The limit of 150 gallons per day per SG is based on the operational LEAKAGE performance criterion in NEI 97-06, Steam Generator Program Guidelines. The Steam Generator Program operational LEAKAGE performance criterion in NEI 97-06 states, "The RCS operational primary to secondary leakage through any one SG shall be limited to 150 gallons per day." The limit is based on operating experience with SG tube degradation mechanisms that result in tube leakage. The operational leakage rate criterion in conjunction with the implementation of the Steam Generator Program is an effective measure for minimizing the frequency of steam generator tube ruptures.

FSAR Amendment 102, Supplement a

LDCR-SA-2008-14, EVAL-2008-002865-01 (TJEW):

Change title from "Director, Oversight & Nuclear Overview" to "Director, Oversight & Regulatory Affairs"

LDCR-SA-2008-15, EVAL-2008-002399-01 (JDS):

ANSI N512-1974 has been replaced with ASTM D 3912 Standard Test Method for Chemical Resistance of Coatings Used in Light-water Nuclear Power Plants which is endorsed by Reg guide 1.54 rev 1. The decontamination test per ANSI 512 was not carried into the replacement standard listed by the ASTM D33 committee that writes these procedures. FSAR Section 6.1B.2 was previously revised in Amendment 102 to remove ANSI N512 and update to current industry standards.

LDCR-SA-2007-15, EVAL-2005-004951-02 (JCH):

Section 10.4.2.2.1 System Operation : page 10.4-8

Deleted reference to priming tank.

Section 10.4.2.5 Instrumentation Requirements: page 10.4-9

Deleted reference to priming tank. Added description of the pressure switch that on low vacuum priming header pressure provides input to a main condenser priming trouble alarm. The main condenser vacuum priming trouble alarm is also activated if the main condenser outlet waterbox vacuum breaker air operated valve is not fully closed.

Justification: The priming tank was removed and a loop seal installed to prevent carry over of the water to the priming pumps due to repetitive reliability problems with the vacuum priming tank level control components.

LDCR-SA-2006-36, EVAL-2005-003364-19 (JDS):

Section 6.2.2 is updated for changes to the sump design and licensing basis to reflect the results of the mechanistic analysis requested in Generic Letter 2004-02. Section 6.2.2 References are administratively updated.

Section 6.2.2 is updated for changes to the sump design and licensing basis to reflect the results of the mechanistic analysis requested in Generic Letter 2004-02. Section 6.2.2.3.3 and 6.2.2.3.4 are revised to reflect the GSI-191 analysis and testing documented in SMF-2001-002201, SMF-2004-003972, and SMF-2005-003364 (see individual references and calculations above) as required by Generic Letter 2004-02. The change to the licensing basis is conservative in that analyses and testing have been performed to the current state of the art.

LDCR-SA-2006-36, EVAL-2005-003364-19 (JDS) (continued):

Section 6.2.2 is updated for changes to the sump design and licensing basis to reflect the results of the mechanistic analysis requested in Generic Letter 2004-02. Table 6.2.2-4 is administratively updated per 10CFR50.71(e) to update and clarify the material description for the sump strainers per SFS-CP-GA-01.

Section 6.3.2.2.10 is updated for changes to the sump design and licensing basis to reflect the results of the mechanistic analysis requested in Generic Letter 2004-02. Section 6.3.2.2.10 is revised to reflect the NPSH analysis for RHR in ME(B)-325 R3.

Table 6.1B-1 is administratively updated per 10CFR50.71(e) to update the quantities of organic materials (cables and oil) from ACTN-MAN-2001-002201-72 and EE-CA-0000-5329.

LDCR-SA-2008-17, EVAL-2008-003064-02 (RAS):

Last sentence in section 6.4.5 incorrectly refers to the "Control Room Envelope Habitability Program" as the "Control Room Integrity Program". This change revises the sentence to use the correct program title.

LDCR-SA-2008-16, EVAL-2008-003163-02 (JCH):

Page 10.2-17 of Section 10.2.3.1, Materials Selection:

Changed compressive residual stress level from " shall not exceed 11,500 psi" to "shall not be lower than 14,504 psi (100 Mpa) and higher than 36,260 psi (250 Mpa) in the middle of the hub area; shall not be lower than 29,007 psi (200 Mpa) and higher than 58, 015 psi (Mpa) in the area of the rim of the hub; shall not be lower than 14, 504 psi (100 Mpa) and higher than 36,260 psi (250 Mpa) in the rim area.

Deleted " For up to 120 percent of rated speed the maximum disk stress at the shrink fit is less than half the burst strength of the material" and inserted " The maximum disk stress at the shrink fit is required to remain less than 50-60% of the yield strength of the material at nominal conditions."

Justification: New advanced design low pressure turbines were installed in Units 1 and 2. Advances in manufacturing techniques and material property selection have resulted in revision to the residual stess criteria. The new advanced design low pressure turbines incorporate disc which have these new advanced manufacturing techniques and new material compositions.

FSAR Amendment 102, Supplement a

LDCR-SA-2008-1, EVAL-2007-002946-02 (JDS):

FSAR changed to state, "Due to the sensitive nature of the seals, seal injection flow should be maintained when the Reactor Coolant System is not completely depressurized or when the Reactor Coolant System inventory is moving through the seal package." During outages seal injection flow has been secured and the RCPs are placed on their backseat which fulfills the intent of this section by isolating the RCP seals from the RCS. With RCPs not on a backseat during refueling, the FSAR was clarified to explain under what circumstances seal injection flow needs to be maintained to assure the RCP seal cleanliness.

LDCR-SA-2008-2, EVAL-2006-003828-04 (GLM):

Due to degradation, non-safety vent chiller X-08 (CPX-CHCICE-08) is being replaced. The replacement is a York YK model higher pressure centrifigul liquid type ventilation chiller using R134a refrigerant. Since this chiller is a direct open versus hermetically sealed compressor a change to Section 9.4E.2 of the FSAR is necessary to reflect the modification changes in FDA-2006-3828-06.

Per FSAR Appendix 9.4E.1, the design function of the plant ventilation chilled water system is to remove heat rejected by plant equipment and to maintain ambient temperature below design limits within the areas it serves. The system is shown on Figure 9.4-11. The plant ventilation chilled water system is not required to mitigate the consequences of an accident or to maintain the plant in a safe shutdown condition. Except for the containment penetrations and containment isolation valves, the plant ventilation chilled water system is non-nuclear safety and non-seismic. By replacing chiller X-08 with a similar 660-ton chiller, the degraded system cooling capacity and efficiency is regained. The new chiller essentially provides the 660 ton desired cooling. This activity, therefore, improves the reliability of the ventilation chilled water system and has no adverse impact on the design function of the system.

LDCR-SA-2009-13, EVAL-2008-000762-02 (GLM):

In the 4th sentence from the bottom, change "Revision 1" to "Revision 0" for NUREG-700 (1981).

This is an editorial change. NUREG-0700, Revision 0 was issued in September 1981 and NUREG-0700, Revision 1 was issued in June 1996.

LDCR-SA-2009-8, EVAL-2009-000832-01 (JCH):

Section 10.2.2.10, Turbine Trips

Page 10.2-15: Delete the following: "The primary water pump shaft vibration trip shown in figure 10.2-1 is allowed to be defeated by the use of a time delay."

Justification: These trips are no longer automatic trips. They are manual. The automatic trips were removed with the installation of the new Turbine Protection System via FDA-2004-000773-01 (Unit 1) and FDA-2004-000773-02 (Unit 2).

Figure 10.2-1, "Turbine Trip Logic Diagram", needs to be revised to remove the logic for the following trips:

-Turb Gen Bearing Vibration (ETP)

-P.W. Pump Shaft Vibration

LDCR-SA-2009-8, EVAL-2009-000832-01 (JCH) (continued):

Justification: These trips are no longer automatic trips. They are manual. The automatic trips were removed with the installation of the new Turbine Protection System via FDA-2004-000773-01 (Unit 1) and FDA-2004-000773-02 (Unit 2).

LDCR-SA-2008-22, EVAL-2008-002039-02 (SCD):

Removes references to TLD readers from section 12.5.2.1. Changes Thermoluminescent dosimetry (TLD) to Optically Stimulated Luminescence (OSL) Badges, replaces TLD with OSL and replaces reference to onsite TLD reading with "The OSL Badges are processed and a definitive dose evaluation is provided by the approved service organization as requested." in section 12.5.2.5. Section 12.5.3.5 is changed to replace Thermoluminescent dosimetry (TLD) to Optically Stimulated Luminescence (OSL) Badges, replaces TLD with OSL and remove reference to onsite dosimetry reading. Requirement for offsite dosimetry service organization to maintain accreditation through the National Voluntary Laboratory Accreditation Program (NVLAP) is incoporated. Table 12.5-1 is changed to delete TLD Readers and Beta, Gamma, and Neutron Used for personnel dosimetry program.

LDCR-SA-2009-2, EVAL-2008-002473-02 (TJD):

Description of Change: Delete "the safety evaluations for" from FSAR section 17.2.1.1.3.1(2), which currently reads: "Review of the safety evaluations for: (1) procedures, (2) change to procedures,equipment, systems or facilities, and (3) tests or experiments where nuclear safety is adversely affected;"

Technical Justification: This change was originally approved as a part of LDCR SA-2000-23, but the current FSAR (Amendment 102) does not reflect the change. From a review of the current and previous FSAR versions, it appears that this portion of LDCR SA-2000-23 was inadvertently not incorporated into the FSAR. (Ref. correspondence, CPSES-200101291 and CPSES-200100873, for information on LDCR SA-2000-23.)

LDCR-SA-2009-6, EVAL-2004-001688-02 (JDS):

Document the use of the RHR pumps to fill the SI accumulators. The previously accepted method to fill and add water to the accumulators is by using the SI pump through the SI test header. When the RCS is less than 350 degrees F, TS 3.4.12 requires that the SI pumps be not "capable of injecting into the RCS." To accomplish accumulator fill with the SI pumps and meet the not "capable of injecting into the RCS" requires 40 fuses to be pulled to remove power to the valves on the SI test header. This method adds unnecessary challenges to equipment reliability (fuse clips) and increases the likelihood of human errors. Pulling 40 fuses is also manpower intensive, particularly during outage periods. Therefore, a method to fill and add water to the accumulator using RHR was implemented.

LDCR-SA-2008-10, EVAL-2007-002677-04 (JCH):

Change Section 5.3.1.5 by adding "and 5.3.4-C" to first paragraph on page 5.3-5.

Justification: Changes reflect the use of a hydraulic nut closure system. The HydraNut is a hydraulically actuated, self-tensioning nut. The result of the installation will be a set of HydraNuts that tension the reactor vessel studs in one operation using hydraulic pressure, as opposed to several passes using stud tensioners currently required for the conventional nuts. As a result, the HydraNut will significantly decrease the time required to tension the reactor vessel studs.

Changed section 5.3.1.7 first paragraph to add the following statement: "Conventional nuts and washers were originally supplied with the reactor vessel. Hydraulic nuts were procured to be used with the reactor vessel studs as appropriate."

Added reference to Table 5.3-4C at the end of paragraph 2.

Justification: Changes reflect the use of a hydraulic nut closure system. The HydraNut is a hydraulically actuated, self-tensioning nut. The result of the installation will be a set of HydraNuts that tension the reactor vessel studs in one operation using hydraulic pressure, as opposed to several passes using stud tensioners currently required for the conventional nuts. As a result, the HydraNut will significantly decrease the time required to tension the reactor vessel studs.

Added new Table 5.3-4C, Unit 1 and 2 Reactor Vessel Closure Bolting Material Properties - Hydranuts & Washers.

Justification: Changes reflect the use of a hydraulic nut closure system. The HydraNut is a hydraulically actuated, self-tensioning nut. The result of the installation will be a set of HydraNuts that tension the reactor vessel studs in one operation using hydraulic pressure, as opposed to several passes using stud tensioners currently required for the conventional nuts. As a result, the HydraNut will significantly decrease the time required to tension the reactor vessel studs.

LDCR-SA-2009-11, EVAL-2009-001859-02 (JDS):

Delete inserts and adaptors from under Closure studs, nuts, washers due to implementation of reactor vessel hydraulic nuts (HydraNuts).

Delete as modified by Code Case 1605 from under SA-540 Class-3 B24. Code case 1605 is not applicable to the Comanche Peak Unit 1 and 2 reactor vessel studs, nuts and washers. The chemistry requirements and increased material size limit for SA-540 Grade B24 bolting material referenced in Code Case 1605 does not apply to the Comanche Peak reactor vessel studs, nuts and washers. The Code Case is also not applicable to the new HydraNut reactor vessel modification.

LDCR-SA-2009-11, EVAL-2009-001859-02 (JDS) (continued):

Delete Code Case 1605. Code case,1605 is not applicable to the Comanche Peak Unit 1 and 2 reactor vessel studs, nuts and washers. The chemistry requirements and increased material size limit for SA-540 Grade B24 bolting material referenced in Code Case 1605 does not apply to the Comanche Peak reactor vessel studs, nuts and washers. The Code Case is also not applicable to the new HydraNut reactor vessel modification.

LDCR-SA-2008-23, EVAL-2008-000624-02 (TJD):

The following sentence is being deleted from FSAR, section 17.2.17, at the top of page 17.2-26: "The Nuclear Overview Department reviews and approves the administrative control procedures and instructions and the retention periods assigned for quality assurance records." This change will make section 17.2.17 consistent with FSAR Section 17.2. Also, FSAR section 17.2 pages 17-ii and 17.2-29 are being revised to reflect current organizational titles.

The review of procedures for quality assurance requirements is now accomplished via the SORC process, as identified in FSAR Section 17.2.2. The change to the SORC process was a reduction in commitment which was reviewed and approved by the NRC via LDCR SA-89-243, therefore; LDCR SA-2008-023 does not constitute a reduction in commitment. Commitment 22910 addresses this review process. Additionally, ACTN-MAN-2008-000624-02 has been created to delete commitment 22906, which discusses the pre-SORC review process and should have been deleted when the current review process was approved by the NRC.

FSAR Amendment 103

LDCR-SA-2004-26, EVAL-2003-000239-03 (SCD):

EVAL-2003-000239-03 (LDCR-SA-2004-026): Corrects note reference for the Heater Drain Tank Equalization Header from "**" to "*". This is an editorial change.

EVAL-2003-000239-03 (LDCR-SA-2004-026): Adds Note 1 to Table 10.4-20 to describe the use of the 2 pH sample points.

EVAL-2003-000239-03 (LDCR-SA-2004-026): Delete dissolved oxygen and pH monitoring from various sample points as identified in FSAR Table 10.4-20. This activity provides new and enhanced models of the existing oxygen and pH analyzers. The Secondary Chemistry Control Program monitoring capabilities will continue to meet the EPRI "PWR Secondary Water Chemistry Guidelines."

LDCR-SA-2009-5, EVAL-2009-000834-02 (CBC):

TMI Section I.A.1.3, "Shift Manning," is updated to reflect the work hour requirements prescribed by 10 CFR Part 26, Subpart I, effective 10/01/2009. Work hour restrictions are being deleted from Technical Specification 5.2.2.d (License Amendment Request 09-006) to support compliance with 10 CFR Part 26. This change will make the FSAR consistent with the Technical Specifications and the new rule. (EVAL-2009-000834-01).

LDCR-SA-2009-7, EVAL-2008-002474-05 (TJD):

Revise the title of FSAR, section 17.2.7.1, from "Receipt Inspection" to "Receipt Inspection and Material Testing."

This change will clearly define the role of the Procurement Quality Assurance Receipt Inspection as "Receipt Inspection and Material Testing."

Revise the first sentence in FSAR, section 17.2.7.1, from "Receipt inspections at CPSES are . . ." to "Receipt inspection and material testing at CPNPP is . . ."

This change will clearly define the role of the Procurement Quality Assurance Receipt Inspection as "Receipt Inspection and Material Testing."

Change FSAR 17.2.7.1, item 2, from CPSES to CPNPP.

Update plant name.

Change FSAR, section 17.2.10, second sentence, from ". . . and 1.116 as . . ." to ". . . 1.116, and 1.123 as . . ."

This change updates the FSAR to include a Regulatory Guide (1.123) that we are currently commited to follow.

Update two places on FSAR page 17.2-20 from CPSES to CPNPP.

FSAR Amendment 103

LDCR-SA-2009-7, EVAL-2008-002474-05 (TJD) (continued):

Update plant name.

Page 17.2-20, Change the wording in the next to last paragraph from ". . . level III inspector . . ." to ". . . Level II or III inspector . . ."

Revise the FSAR to allow a Level II inspector to assign hold points and ensure that inspection methods are adequate.

LDCR-SA-2009-17, EVAL-2007-001302-01 (TJD):

Revise the Discussion section for Regulatory Guide 1.33 to include an additional exception for commercial grade calibrations.

This change supports a new option for NVLAP or A2LA accredidation of commercial grade calibration services in lieu of supplier audit by licensee.

Revise the Discussion section for Regulatory Guide 1.123 to include an additional exception for commercial grade calibrations.

This change supports a new option for NVLAP or A2LA accredidation of commercial grade calibration services in lieu of supplier audit by licensee.

Revise the Discussion section for Regulatory Guide 1.144 to include an additional exception for NVLAP or A2LA accredited commercial grade calibrations.

This change supports a new option for NVLAP or A2LA accredidation of commercial grade calibration services in lieu of supplier audit by licensee.

Revise FSAR section 17.2.4 to describe the procurement document control requirements needed to support the use of NVLAP or A2LA accredited commercial grade calibration services.

This change supports a new option for NVLAP or A2LA accredidation of commercial grade calibration services in lieu of supplier audit by licensee.

Revise FSAR section 17.2.7 to describe changes to the control of purchased safety-related material, equipment and services needed to support the use of NVLAP or A2LA accredited commercial grade calibration services.

This change supports a new option for NVLAP or A2LA accredidation of commercial grade calibration services in lieu of supplier audit by licensee.

Revise FSAR section 17.2.18.1, "Audit Organizations," to explain the audit implications when using NVLAP or A2LA accredited commercial grade calibration services.

FSAR Amendment 103

LDCR-SA-2009-10, EVAL-2005-000768-02 (TJD):

This change supports a new option for NVLAP or A2LA accredidation of commercial grade calibration services in lieu of supplier audit by licensee.

FSAR Table 2.5.6-7, Station 46+17, the Type should be changed from "Pneumatic" to "Pneumatic (Abandoned)"

This change updates the table to reflect changes to the SCR dam piezometers.

FSAR Table 2.5.6-7, Station 55+95, the Type should be changed from "Pneumatic" to "Pneumatic (Abandoned)"

This change updates the table to reflect changes to the SCR dam piezometers.

FSAR Table 2.5.6-7, Station 56+05, the Type should be changed from "Pneumatic" to "Wellpoint (Replaced)"

This change updates the table to reflect changes to the SCR dam piezometers.

FSAR Table 2.5.6-7, Station 56+05, the Piezometer No. should be changed from "P-II-1a" to "P-II-1" The "a" needs to be removed from the piezometer number.

This change corrects the SCR dam piezometer number.

FSAR Table 2.5.6-7, Station 56+02, the Type should be changed from "Wellpoint" to "Wellpoint (Replaced)"

This change updates the table to reflect changes to the SCR dam piezometers.

FSAR Table 2.5.6-7, Station 56+22, the Type should be changed from "Wellpoint" to "Wellpoint (Abandoned)"

This change updates the table to reflect changes to the SCR dam piezometers.

FSAR Table 2.5.6-7, Station 56+92, the Type should be changed from "Wellpoint" to "Wellpoint (Replaced)"

This change updates the table to reflect changes to the SCR dam piezometers.

FSAR Table 2.5.6-7, Station 56+06, the Type should be changed from "Pneumatic" to "Pneumatic (Abandoned)"

This change updates the table to reflect changes to the SCR dam piezometers.

FSAR Table 2.5.6-7, Station 69+00, the Type should be changed from "Wellpoint" to "Wellpoint (Replaced)"

LDCR-SA-2009-10, EVAL-2005-000768-02 (TJD) (continued):

This change updates the table to reflect changes to the SCR dam piezometers.

FSAR Table 2.5.6-7, Station 69+05, the Type should be changed from "Wellpoint" to "Wellpoint (Abandoned)"

This change updates the table to reflect changes to the SCR dam piezometers.

FSAR Table 2.5.6-7, Station 69+15, the Type should be changed from "Wellpoint" to "Wellpoint (Abandoned)"

This change updates the table to reflect changes to the SCR dam piezometers.

FSAR Table 2.5.6-7, Station 69+09, the Type should be changed from "Pneumatic" to "Pneumatic (Abandoned)"

This change updates the table to reflect changes to the SCR dam piezometers.

FSAR Table 2.5.6-7, Station 69+20, the Type should be changed from "Pneumatic" to "Pneumatic (Abandoned)"

This change updates the table to reflect changes to the SCR dam piezometers.

FSAR Figure 2.5.6-56 is updated to reflect the same piezometer changes that were made to FSAR Table 2.5.6-7, as detailed in the previous 13 records of this database.

This change updates Figure 2.5.6-56 to reflect changes to the SCR dam piezometers.

LDCR-SA-2009-16, EVAL-2009-003424-01 (TJEW):

On Table 8.3-3, sheet 1, for items:

3A, revise the words, "loss of power to buses 1EA1 and 1EA2 from XST1"

to read, "For open circuit: Loss of alternate power to buses 1EA1 and 1EA2 from XST1.

For short circuit: Loss of power to buses 2EA1, 2EA2, and loss of alternate power source for buses 1EA1 and 1EA2."

3B, revise the words, "loss of power to buses 2EA1 and 2EA2 from XST1"

to read, "For open circuit: Loss of power to buses 2EA1 and 2EA2 from XST1.

LDCR-SA-2009-16, EVAL-2009-003424-01 (TJEW) (continued):

For short circuit: Loss of power to buses 2EA1, 2EA2, and loss of alternate power source for buses 1EA1 and 1EA2."

On Table 8.3-3, sheet 2, for items:

4A, revise the words, "loss of power to buses 1EA1 and 1EA2 from XST2"

to read, "For open circuit: Loss of power to buses 1EA1 and 1EA2 from XST2.

For short circuit: Loss of power to buses 1EA1, 1EA2, and loss of alternate power source for buses 2EA1 and 2EA2."

4B, revise the words, "loss of power to buses 2EA1 and 2EA2 from XST2"

to read, "For open circuit: Loss of alternate power to buses 2EA1 and 2EA2 from XST2.

For short circuit: Loss of power to buses 1EA1, 1EA2, and loss of alternate power source for buses 2EA1 and 2EA2."

LDCR-SA-2009-3, CR-EVAL-2009-000413-01 (SCD):

Changes to CPNPP Executive Management assignments and Maintenance Department reorganization.

LDCR-SA-2009-23, EVAL-2006-003201-02 (TJEW):

The revised duty cycle load of the batteries envelops the calculated duty cycle load of the batteries and will maintain the end of the duty cycle battery voltage of 1.75 VPC = battery voltage of 105V, as required by Section 4.1.2.1.B of DBD-EE-044 Rev 24 and FSAR section 8.3.2.1 item "2" Capacity sub item "a" Batteries. Ref calculation EE-CA-0000-5454 Rev 0. The listing of enveloping duty cycle load capability of battery in Table 8.3-4 will minimize unnecessary FSAR changes when a battery load changes but remain bounded by the enveloping load. 59SC-2006-003201-01-00 provide the basis that a 50.59 evaluation is not required for this change.

FSAR Table 8.3-4 is revised to list the duty cycle load of batteries which envelop the batteries calculated load and maintains end of the duty cycle voltage of 105V.

FSAR Amendment 103

LDCR-SA-2008-11, CR-EV-2006-003080-00-150 (JCH):

Table 10.4-10: Maximum System Heat Sink Requirements

1.Exciter air coolers: The turbine generator exciter air coolers currently have a heat load of 2.143x10^6 Btu/hr, this will be increased to 2.184x10^6 Btu/hr for SPU. Additionally, the exciter air coolers currently have a cooling water flow rate of 790 gpm, this will be increased to 792.5 gpm for SPU.

LDCR-SA-2008-11, CR-EV-2006-003080-00-150 (JCH) (continued):

2.Hydrogen coolers: The turbine generator Hydrogen coolers currently have a heat load of 17.02x10^6 Btu/hr, this will be decreased to 16.79x10^6 Btu/hr for SPU. Additionally, the Hydrogen coolers have a cooling water flow rate of 4480 gpm, this will be decreased to 4403 gpm for SPU.

3. Isophase forced cooling unit: The isophase bus forced cooling units currently have a heat load of 1.03x10^6 Btu/hr, this will be increased to 1.808x10^6 Btu/hr for SPU. Additionally, the isophase forced cooling units have a cooling water flow rate of 137 gpm, this will be increased to 220 gpm for SPU.

4. Primary water coolers: The turbine generator primary water coolers currently have a heat load of 31.17x10^6 Btu/hr, this will be increased to 32.70x10^6 Btu/hr for SPU. Additionally, the primary water coolers have a cooling water flow rate of 5720 gpm, this will be increased to 7115 gpm for SPU. To accomplish this five of six cooler will be placed in operation for SPU, currently four of six coolers are in operation.

Justification:

Heat load, flow, and pressure requirements for the exciter air coolers, Hydrogen coolers, and primary water coolers can be found in Vendor Document EC-06153 "Thermal Uprate Study 4.5% for TXU Comanche Peak Units 1 and 2" (Ref ENR-2008-003080-12). Heat load for these coolers is calculated using conservative assumptions, each cooler has its own set of conservative conditions.

Heat load and flow requirements for the isophase bus forced cooling units can be found in Section 3.13.1 of ER-SPU-4.2.6 "Turbine Plant Cooling Water System" (Ref ENR-2008-003080-39).

These changes are required to maintain configuration control.

Section 10.2.2.6.1: Hydrogen Storage and Supply

Hydrogen pressure will be increased to 65 psig for SPU, currently pressure is 60 psig.

LDCR-SA-2008-11, CR-EV-2006-003080-00-150 (JCH) (continued):

Justification:

Heat load, flow, and pressure requirements for the exciter air coolers, Hydrogen coolers, and primary water coolers can be found in Vendor Document EC-06153 "Thermal Uprate Study 4.5% for TXU Comanche Peak Units 1 and 2" (Ref ENR-2008-003080-12). Heat load for these coolers is calculated using conservative assumptions, each cooler has its own set of conservative conditions.

Heat load and flow requirements for the isophase bus forced cooling units can be found in Section 3.13.1 of ER-SPU-4.2.6 "Turbine Plant Cooling Water System" (Ref ENR-2008-003080-39).

These changes are required to maintain configuration control.

Section 10.4.12.1: Design Basis

The TPCW system currently has a maximum operating heat exchanger outlet temperature of 105F, this will be increased to 107F for SPU. Currently the circulating water temperature that flows through the tube side of the TPCW heat exchanger is 95F, this will be increased to 102F post-SPU.

Justification:

Heat load, flow, and pressure requirements for the exciter air coolers, Hydrogen coolers, and primary water coolers can be found in Vendor Document EC-06153 "Thermal Uprate Study 4.5% for TXU Comanche Peak Units 1 and 2" (Ref ENR-2008-003080-12). Heat load for these coolers is calculated using conservative assumptions, each cooler has its own set of conservative conditions.

Heat load and flow requirements for the isophase bus forced cooling units can be found in Section 3.13.1 of ER-SPU-4.2.6 "Turbine Plant Cooling Water System" (Ref ENR-2008-003080-39).

These changes are required to maintain configuration control.

LDCR-SA-2008-12, CR-EV-2006-003080-00-103 (JCH):

Section 10.4.10.5 : remove the following "Heater drain tank control valves to heaters 3A and 3B are interlocked to close when the corresponding extraction steam motorized stop valve is colsed. Note however that Operations may set vent valves in the OPEN position by pulling their fuses. The Heater Drain System Operating Procedures will control the valves configuration."

FSAR Amendment 103

LDCR-SA-2008-12, CR-EV-2006-003080-00-103 (JCH) (continued):

Justification: The 3A and 3B heater drain tank control vent valves are being removed and replaced with straight pipe to allow free flow of steam from the heater drain tanks to the 3A and 3B heaters. This will allow the heater drain system to vent with less restriction and better respond to plant trainsients after the power uprate. The valves are currently locked open and act as an oriface or restriction in the line impeeding proper steam vent flow.

Section 10.4.11.5: remove the following "Heater drain tank control vent valves to heater 3A and 3B are interlocked to close when the corresponding extraction steam motorized stop valve is closed. Note the vent valves may be disabled in the open position by removing the control fuses and/or isolating the positioner instrument air supply and restraining the valve handwheels. The vent globe valves are air operated and fail open"

Justification: The 3A and 3B heater drain tank control vent valves are being removed and replaced with straight pipe to allow free flow of steam from the heater drain tanks to the 3A and 3B heaters. This will allow the heater drain system to vent with less restriction and better respond to plant trainsients after the power uprate. The valves are currently locked open and act as an oriface or restriction in the line impeeding proper steam vent flow.

LDCR-SA-2008-20, CR-EV-2007-002129-00-4 (JCH):

Section 13.3B.1.1 Plant Manager:

Revised Plant Manager responsibilities to be maintenance and implementation of the Fire Protection Progrram, not development.

Justification: This change is required due to various personnel and organizational changes as CPNPP. This change is administrarive in nature and does not change the Fire Protection Program requirements at CPNPP.

13.3B.1.2 Director, Maintenance:

Director, Maintenance responsible for maintenance and implementation of the Fire Protection Program, not implementation.

The Manager, Technical Support does not report to him so the reference to him was deleted.

13.B.1.3 Director, Site Engineering:

Added new section for Director Site, Engineering who is responsible for the development of the Fire Protection Program. This responsibility is assigned to the Manager, Technical Suport.

LDCR-SA-2008-20, CR-EV-2007-002129-00-4 (JCH) (continued):

13.B.1.4 Manager, Technical Support:

Manager, Technical Support is responsible to the Director, Site Engineering instead of the Director, Maintenance.

Added the responsibility for "review and apporval of Fire Protection Design documents, licensing documents, and Station Procedures including revisions, to verity technical accuracy and regulatory compliance.

Added the following paragraph- "The Manager, System Engineering is responsible to the Director, Site Engineering for technical support of the Fire Protection Program in relation to the review and implementation of design modifications and the resolution of system issues.

13.3B.1.5 Maintenance Team Manager:

Deleted "Smart" from Maintenance Team Manager title.

Added responsibility "to assist the Nuclear Training Manager in the development and implementation of fire protection training programs for personnel and the fire brigade at CPNPP.

Justification: This change is required due to various personnel and organizational changes as CPNPP. This change is administrarive in nature and does not change the Fire Protection Program requirements at CPNPP.

LDCR-SA-2008-13, CR-EV-2006-003080-94 (JDS):

Incorporate Westinghouse Topical Reports associated with conversion to the Westinghouse transient and accident analysis methodologies.

Include relevant information resulting from the removal of Appendix 4.A and 4.B into this section for consistency with other Westinghouse plants using the Westinghouse transient and accident analysis methodologies.

Remove Appendix 4.A and incorporate the relevant information into chapters 4.1, 4.2, 4.3, and 4.4 for consistency with other Westinghouse plants using the Westinghouse transient and accident analysis methodologies.

Update Chapter 6.2 to reflect GOTHIC code analysis provided to the NRC for containment accident conditions resulting from 4.5% power uprate of Units 1 and 2.

Insert Tables to reflect GOTHIC code analysis provided to the NRC for containment accident conditions resulting from 4.5% power uprate of Units 1 and 2.

LDCR-SA-2008-13, CR-EV-2006-003080-94 (JDS) (continued):

Replace Tables to reflect GOTHIC code analysis provided to the NRC for containment accident conditions resulting from 4.5% power uprate of Units 1 and 2.

Remove Table as table does not reflect GOTHIC code analysis provided to the NRC for containment accident conditions resulting from 4.5% power uprate of Units 1 and 2.

Modify Table to reflect GOTHIC code analysis provided to the NRC for containment accident conditions resulting from 4.5% power uprate of Units 1 and 2.

Delete Tables which does not reflect GOTHIC code analysis provided to the NRC for containment accident conditions resulting from 4.5% power uprate of Units 1 and 2.

Insert Figures to reflect GOTHIC code analysis provided to the NRC for containment accident conditions resulting from 4.5% power uprate of Units 1 and 2.

Describe Power Distribution Monitoring System Using BEACON.

Update time required for boric acid solution to counteract xenon decay when charging to the RCS is via reactor coolant

pump seal injection at the rate of approximately 5 gpm per pump from approximately 3.5 hours to 6 hours. This is consistent with the Westinghouse Methodology.

Revise this section for consistency with Westinghouse transient and accident analysis methodologies now used on Units 1 and 2.

Revise these Tables for consistency with Westinghouse transient and accident analysis methodologies now used on Units 1 and 2.

Replace this figure for consistency with Westinghouse transient and accident analysis methodologies now used on Units 1 and 2.

Insert these Figures for consistency with Westinghouse transient and accident analysis methodologies now used on Units 1 and 2.

Revise these sections for consistency with Westinghouse transient and accident analysis methodologies now used on Units 1 and 2.

Insert these Tables for consistency with Westinghouse transient and accident analysis methodologies now used on Units 1 and 2.

Update Table on Reactor Design Comparison for consistency with uprated conditions of Units 1 and 2.

LDCR-SA-2008-13, CR-EV-2006-003080-94 (JDS) (continued):

Update Table on Analytical Techniques in reactor design for consistency with Westinghouse Methodologies used.

Insert Table on Thermal and Hydraulic Comparison for pre- and post- uprate conditions of Units 1 and 2.

LDCR-SA-2009-19, CR-EV-2009-000214-11 (JDS):

Update Chapter 9 to modify the time required to add enough boric acid solution to bring the plant to hot shutdown and counteract xenon decay if normal charging is unavailable.

Update Chapter 4 to include a description of the Westinghouse Integrated Nozzle (WIN) top nozzle design. The mechanical design evaluations idocument that the new fuel assemblies are compatible with existing fuel, reactor vessel internals, spent fuel racks, fuel handling equipment and RCCAs and that all structural integrity and seismic requirements are satisfied.

LDCR-SA-2007-10, CR-EV-2006-003080-202 (JDS):

Revise the Main Generator rating from 1350 MV to 1410 MVA for each Unit in the first sentence of the second paragraph insection 1.2.2.5.

Revised the titles for Figures 10.1-1 and 10.1-2 as follows:

10.1-1 Unit 1, 100% Power Heat Balance (See VL-07-001239)

10.1-2 Unit 2, 100% Power Heat Balance (See VL-07-001240)

The existing figures are replaced with new heat balance drawings supplied by Siemens. These figures contain information proprietary to Siemens. Consequently, no figures will be included but the List of Figures is revised to refer to the vendor control number for the drawings which can be accessed via the plant record system.

Revised the sixth paragraph in section 10.1 as follows:

"Heat balances reflecting the design at an NSSS rated thermal power of 3628 MWt (maximum guaranteed rating) are shown on Figures 10.1-1 and 10.1-2, respectively. The rating of the electric generator is 1,410,000 kVA, 60 Hz, 0.90 power factor."

Replace the 2nd and 3rd paragraphs with the following:

"The Unit 1 turbine generator is designed to produce 1263.4 MWe when operating at 14,774,975 lb/hr saturated steam at 980 psia and 1192.3 Btu/lb with 0.21% moisture at the throttle and 1.414 in Hg absolute at the turbine exhaust. The Unit 2 turbine generator is idesigned to produce 1253.4 MWe when operating at 14,715,715 lb/hr saturated steam

LDCR-SA-2007-10, CR-EV-2006-003080-202 (JDS) (continued):

at 948.9 psia and 1192.1 Btu/lb with 0.40% moisture at the throttle and 1.414 in Hg absolute at the turbine exhaust."

Revise the main generator kVA rating in the first sentence in section 10.2.2.6 by replacing "1,350,000" with "1,410,000" and deleting "and a short circuit ratio of 0.58."

In section 10.2.2.6.1, reevise the maximum pressure in the second sentence from "60" psig to "75" psig.

In section 10.4.1.1.1, revise the value for:

Exhaust steam from "8 x10E6" to "8.44x10E5"

Condenser duty from "7.7x10E9" to "8.06x10E9"

Condenser pressure at turbine exhaust from "3.5" to "3.55"

Outlet temperature form "110" to "110.8".

In section 10.4.5.1, in the third sentence, revise the value for total heat removed from "8.4X10E9" to "8.8x10E9" and amount removed from the main cindenser from "8.0x10E9" to "8.4x10E9".

Delete Figures 10.1-1 and 10.1-2 for Unit 1 100% Power Heat Balance and Unit 2 100% Power Heat Balance

Replace existing Table 10.1-1 with new Table reflecting new values for Maximum Guaranteed Rating for Unit1 and for Unit 2. Delete the column for "Valves Wide Open" values.

LDCR-SA-2004-18, EVAL-2003-000167-02 (JDS):

This Activity installs neutron dosimetry sensors used to monitor neutron exposure for continued surveillance of reactor vessel integrity. The equipment is installed in the reactor cavity annulus in all four quadrants utilizing the neutron detector well ventilation ducts for support.

By installing the Ex-Vessel Dosimetry, an alternative dosimetry program is instituted to monitor reactor vessel neutron exposure through the license renewal period. Therefore, CPSES is following the guidance for reactor vessel surveillance as stated in the NUREG-1801, "Generic Aging Lessons Learned (GALL) Report," April 2001.

FSAR Amendment 103a

LDCR-SA-2009-12, EV-CR-2008-003459-00-11 (SCD):

Amend UFSAR Section 6.2.4.1.3.1 to change the containment isolation valve typical arrangements applied to the high head safety injection lines and to describe that pressure indication is provided to monitor ECCS piping pressure.

Add Section 6.3.5.2.6 and REFERENCES to the Table Of Contents, add Section 6.3.5.2.6 to describe CPNPP response to GL 2008-01, describe the new ECCS piping pressure monitoring function and add Reference section with GL 2008-01 as a reference.

Amend UFSAR Figure 6.2.4-1 Valve Arrangement 9 to depict the locked closed manual containment isolation valve and downstream pressure transmitter.

Amend UFSAR Figure 6.2.4-1 to add new Valve Arrangement 46.

Amend UFSAR Section 5.2.5.2.3 to describe that pressure indication is provided to monitor ECCS piping pressure.

LDCR-SA-2008-19, EV-CR-2007-002125-00-2 (JCH):

13.3.B.5 QUALITY ASSURANCE PROGRAM

1. Design Control and Procurement Document Control

Changed first paragraph to read as follows:

"Measures will be established to assure that NRC applicable guidelines or NRC approved alternatives are included in design and procurement documents and that any deviations therefrom are controlled. There procedures include provisions, as necessary, to ensure that:"

4. Inspection

Changed to read as follows:

"A program for independent inspection of activities affecting fire protection will be established and executed by, or for, the organization performing the activity to verify conformance with documented installation drawings and test procedures for accomplishing the activity."

Justification:

The proposed changes revise the language in FSAR 13.3B.5 to reflect the guidance language in Appendix A to BTP APCSB 9.5-1. CPSES is committed to the meet the requirements of Appendix A to BTP APCSB 9.5-1 as stated in NRC SSERs 1, 12, and 21.

The changes will not adversely affect the ability to achieve and maintain safe shutdown in the event of a fire.

LDCR-SA-2008-19, EV-CR-2007-002125-00-2 (JCH) (continued):

13.3.B.5 QUALITY ASSURANCE PROGRAM

5. Test and Test Control

Added the following sentence:

"Test results will be properly evaluated and acted on.

7. Nonconforming Items.

Changed to read as follows:

"Measures are established to control items that do not conform to specified requirements to prevent inadvertent use of installation."

8. Corrective Action

Changed to read as follows:

"Measures will be established to ensure that conditions adverse to fire protection such as failures, malfunctions, deficiencies or deviations, defective components, uncontrolled combustible material and non-conformances are promptly identified, reported, and corrected."

10. Evaluations

Changed heading to "Audits".

Changed to read:

"Audits will be conducted and documented to verify compliance with the fire protection program, including design and procurement documents, instructions, procedures and drawings, and inspection and test activities. These audits will be performed by personnel not having direct responsibility for the Fire Protection Program."

Justification:

The proposed changes revise the language in FSAR 13.3B.5 to reflect the guidance language in Appendix A to BTP APCSB 9.5-1. CPSES is committed to the meet the requirements of Appendix A to BTP APCSB 9.5-1 as stated in NRC SSERs 1, 12, and 21.

The changes will not adversely affect the ability to achieve and maintain safe shutdown in the event of a fire.

FSAR Amendment 103a

LDCR-SA-2010-2, EV-CR-2005-003122-00-4 (JCH):

6. Inspection, Test and Operating Status.

Change to read "Measures will be established to provide for the identification of items that have satisfactorily passed required tests and inspections.

Justification:

FSAR Section 13.3B.5.6 should reflect what is stated in C.6 of Appendix A to BTP APCSB 9-5.1 and should not contain the language related to tagging of non-conformances. Non-conformances are discussed in FSAR 13.3B5.7. As presently worded this section can lead to unintended and overly restrictive requirements placed on the Fire Protection Program. This change will not adversely affect the ability to achieve and maintain safe shutdown in the event of a fire.

LDCR-SA-2009-24, EV-CR-2006-004121-00-1 (JDS):

Add a paragraph to document the use of the demineralized water storage tank and transfer pump to manually makeup to the containment spray pump suction piping located downstream of the containment sump isolation valves. The change allows for the fill of a section of containment spray pump suction piping with demineralized water, rather than borated water. This method is also used to fill the containment spray risers in containment.

LDCR-SA-2010-11, EV-CR-2010-001826-00-5(TJD):

Delete all the text in the Discussion section of Regulatory Guide 1.16, and replace it with the following: "This regulatory guide was withdrawn on August 11, 2009."

Technical Justification: Regulatory Guide 1.16 was withdrawn by the NRC on August 11, 2009 (Ref. Federal Register, 74 FR 40244, 8/11/2009).

Delete the following sentence from the CPSES Response portion of FSAR section II.K.3.3, "All challenges to SV or RV shall be documented in the monthly operating report." Then replace the deleted sentence with the following: "The reporting of SV & RV challenges was moved from the annual report to the monthly operating report (TS 6.9.1.5), then License Amendment 64 deleted this reporting requirement altogether."

Technical Justification: License Amendment 64 was implemented in July 1999 and deleted TS 6.9.1.5, including the requirement to report challenges to PORVs and safety valves, which was being reported in the annual operating report.

FSAR Amendment 103a

LDCR-SA-2009-25, EV-CR-2007-002527-00-2 (TJEW):

Changes to the AAP are controlled by the site facility program (reference STA-716) and are not required to be tracked as plant equipment. Therefore, the current AAP configuration will not be tracked on plant drawing, and drawing M1-0313 Sht A Sht - will be retired. This activity has no adverse impact on the design function of any SSC because the drawings that are being retired reflect a component was not implemented in the field and have inaccurate depictions of the current AAP status.

Delete the reference to M1-0310-A on Sheet 12 of Table 3.2-3

Changes to the AAP are controlled by the site facility program (reference STA-716) and are not required to be tracked as plant equipment. Therefore, the current AAP configuration will not be tracked on plant drawing, and drawing M1-0313 Sht A Sht - will be retired. This activity has no adverse impact on the design function of any SSC because the drawings that are being retired reflect a component was not implemented in the field and have inaccurate depictions of the current AAP status.

Delete the reference to M1-0310-A on Sheet 10 of Table 3.2-4

Changes to the AAP are controlled by the site facility program (reference STA-716) and are not required to be tracked as plant equipment. Therefore, the current AAP configuration will not be tracked on plant drawing, and drawing M1-0313 Sht A Sht - will be retired. This activity has no adverse impact on the design function of any SSC because the drawings that are being retired reflect a component was not implemented in the field and have inaccurate depictions of the current AAP status.

Delete the reference to M1-0310-A on page 9-xv

LDCR-SA-2009-21, EV-CR-2009-000214-00-8 (JDS):

The misloaded assembly analysis methodology described in the FSAR is being changed from the Luminant Power methods detailed in topical report RXE-91-002 to the original Westinghouse methodology previously reviewed and approved for Comanche Peak by the NRC (NUREG-0797, Section 15.3.3). This change is necessary to fully complete the transition to the Westinghouse accident analysis methodology. An improved description of the original Westinghouse methodology has been recently provided in WCAP-16676-NP which is also referenced as part of the adoption of the misloaded assembly analysis methodology. The improved description (WCAP-16676-NP) provides additional clarifying details regarding the original methodology but does not modify or alter the method relative to the original Westinghouse methodology approved by the NRC for Comanche Peak (NUREG-0797, Section 15.3.3). The specific application of the methodology is to analyze reactor operation with a fuel assembly inadvertently loaded into an improper location. Luminant Power is using the original analysis methodology approved for Comanche Peak in the specific application as approved by the NRC. The SER did not require any additional restrictions or limitations beyond those described in the methodology.

Update table of contents to reflect revised section.

FSAR Amendment 103a

LDCR-SA-2010-10, EV-CR-2009-000465-00-3 (JDS):

Recently, Westinghouse determined that existing Rod Withdrawal at Power (RWAP) RCS overpressure analyses do not cover the full range of reactor power operations for all Westinghouse-designed PWRs (W-PWRs).

Westinghouse performed generic RWAP analyses to demonstrate that the peak RCS pressure criterion was met for most W-PWRs equipped with a positive flux rate reactor trip (PFRT).

Additionally, an evaluation was performed against a generic analysis for Comanche Peak Units 1 and 2. The evaluation against the generic RWAP overpressure analyses concluded that credit for the PFRT was sufficient to demonstrate compliance with the RCS overpressure criterion. Westinghouse has performed analyses for various plants to conservatively calculate Reactor Coolant System (RCS) pressure following a Rod Withdrawal at Power (RWAP) event. Specifically, the Westinghouse analysis for Comanche Peak Units 1 and 2 calculated an acceptable result for RCS peak pressure.

Comanche Peak has reviewed the information and this FSAR update captures the appropriate information from the evaluation regarding the safety analysis by adding the Uncontrolled RCCA Bank Withdrawal to the Power Range high positive neutron flux rate trip discussion.

Comanche Peak has reviewed the information and this FSAR update captures the appropriate information from the evaluation regarding the safety analysis by inserting Power range high flux rate in the uncontrolled rod cluster control assembly bank withdrawal at power.

Recently, Westinghouse determined that existing Rod Withdrawal at Power (RWAP) RCS overpressure analyses do not cover the full range of reactor power operations for all Westinghouse-designed PWRs (W-PWRs).

Comanche Peak has reviewed the information and this FSAR update captures the appropriate information from the evaluation regarding the safety analysis by updationg the reactor protection system automatic features with a discussion of a trip when any two of four power range neutron flux high positive rate channels exceed a setpoint.

FSAR Amendment 103b

LDCR-SA-2010-6, EV-CR-2003-002117-00-2 (JCH):

Section 10.4, Table 10.4-13 (Auxiliary Steam System Requirements)

Description of Change:

Modify the entry stating that the Turbine Gland Steam System is only required by the Feedwater Pump Turbine during startup only to add "Power Operations: 230 (115 Each) 60-150 psig SAT".

Technical Justification:

The Auxiliary Steam System supplies 150 psig steam to the Feedwater Pump Turbine (FWPT) Gland Steam (GS) supply valves (u-PV-3918A). The GS supply valves reduce the 150 psig Auxiliary Steam (AS) supply to 2-4 psig. Each GS supply valve supplies both FWPTs for the associated unit.

This LDCR will change FSAR Table 10.4-13 to agree with the current FSAR description of the AS/GS system operation.

The FSAR Turbine GS System description states the following (10.4.3.2(1.b) :

“The pressure at the high-pressure end is insufficient to seal the low-pressure seals. Auxiliary steam from the Auxiliary Steam System is provided at the inner annular chambers through the steam seal supply valve.”

The FSAR Turbine GS System design bases states the following (10.4.3.1(2) :

“The seal steam supply header has a normal flow rate of 230 lb/hr at 2 to 4 psig. At startup, 1150 lb/hr of auxiliary steam from the Auxiliary Steam System is supplied at 2 to 4 psig.”

This indicates that the FWPT seals are not self-sealing, and the flow rate of the seal steam will vary with loading, from 1150 lb/hr at startup to 230 lb/hr during normal plant operations.

LDCR-SA-2009-9, EV-CR-2007-001888-00-6 (RAS):

Insert a parenthetical reference to Fig. 1.2-8 and 1.2-15 in the 1st sentence of the 3rd paragraph to clarify the physical location of the Jib Crane on the 905 level of the Containment.

In the 4th sentence of the 3rd paragraph, replace "Crane" with "telescopic jib crane" to clarify the particular crane of interest.

LDCR-SA-2009-9, EV-CR-2007-001888-00-6 (RAS) (continued):

In the last sentence of the 3rd paragraph, replace "jib" with "The telescopic jib" to clarify the particular crane of interest

Insert the following immediatley after the 3rd paragraph to describe the administrative controls applicable to Jib Crane operation:

"Both the Polar Crane and the Telescopic Jib Crane operating at the same time constitutes Multi-crane Operation which requires special administrative controls to reduce the likelihood of unplanned crane interactions. These administrative controls include a qualified multi-crane coordinator located in a position of good visibility to opbserve both cranes."

Revise the first four sentences of the last paragraph as follows:

"A Containment Anti-Collision Control System is also installed on the telescopic jib crane to reduce the likelihood of unplanned crane interactions with the polar crane bridge. The function of the Progammable Logic Controller (PLC) and associated components is to keep the jib crane boom below the Polar Crane bridge. In addition, an administratively controlled key, which is normally placed in the Polar Crane allows full operation from the polar crane radio controller. In this mode without the key, the PLC restricts the height of the Jib Crane boom."

Delete the following last sentence from the last paragraph:

"These administrative controls include a multi-crane coordinator located in a position of good visibility to observe both cranes."

Insert a reference to Figure 9.1-14 at the end of the first paragraph.

Insert the following sentence at the end of the second paragraoh:

"See section 9.1.4.3.2 for the Polar Crane seismic considerations. See section 3.8.3.4.10 for the applicable industry standard."

Insert the following paragraph following the 2nd paragraph:

"A telescopic jib crane is also provided inside Containment for refueling and maintenance. It is supported by a structural steel support mounted on the east-west divider wall between S. G. compartments at elevation 905'-9". Both the Polar Cane and Telescopic Jib Crane operating at the same time constitutes Multi-crane Operation which requires special administrative controls to reduce the likelihood of unplanned crane interactions. See section 3.8.3.1.2 for a description of the administrative controls and design features for the Polar Crane and the Telescopic Jib Crane."

FSAR Amendment 103b

LDCR-SA-2010-7, EV-CR-2010-003216-6 (SCD):

Modify the FSAR to provide the flexibility of using the normal Gas Decay Tanks in a Shutdown Gas Decay Tank capacity in the event that any of the designated Shutdown Gas Decay Tanks become degraded. The designated Shutdown Gas Decay Tanks are normally used during plant startup and shutdown. This system performs no function related to the safe shutdown of the plant. [11.3.2.1.1] This change has no safety impact on the plant.

LDCR-SA-2010-13, EV-CR-2010-002062-19 (TJD):

Add the following sentence to the end of FSAR section 2.4.13.1.5:

A Groundwater Monitoring Program is established and incorporates several sentinel wells in various locations throughout the plant site for prompt identification of potential radiological release source locations.

Justifcation - Update FSAR to include information on groundwater monitoring program from May 2010 hydrogeology study performed by Pastor, Behling, & Wheeler.

Change FSAR section 2.4.13.4 to read as follows (delete end of existing sentence #1, and add new sentence after existing sentence #1):

No planned releases to the ground water environment will take place at the plantsite. However a Groundwater Monitoring Program exists for early detection of inadvertent releases of radioactive material. Pertinent information is provided in Section 6.1 of the Environmental Report.

Justifcation - Update FSAR to include information on groundwater monitoring program from May 2010 hydrogeology study performed by Pastor, Behling, & Wheeler.

LDCR-SA-2010-9, EV-CR-2010-000988-14 (TJD):

Change Executive Vice President & Chief Nuclear Officer title to Senior Vice President & Chief Nuclear Officer.

Justification - Update of VP title.

Also, revise section 17.2.1.3.2, item 3., to read as follows:

Audit program review reports encompassed by Section 17.2.1.3.1(7) shall be forwarded to the Senior Vice President & Chief Nuclear Officer within 30 days following completion of the review.

Justification - Clarify the distribution requirements for audit program review reports.

LDCR-SA-2010-9, EV-CR-2010-000988-14 (TJD) (continued):

Section 17.2.18:

Change the second paragraph in section 17.2.18 to add the following sentence after the existing first sentence: "Audit reports shall be forwarded to the Senior Vice President & Chief Nuclear Officer and to the management positions responsible for the areas audited within 30 days after completion of the audit by the auditing organization."

The new second paragraph will read as follows:

Planned and periodic audits are performed in accordance with written procedures to verify compliance with all aspects of the quality assurance program. Audit reports shall be forwarded to the Senior Vice President & Chief Nuclear Officer and to the management positions responsible for the areas audited within 30 days after completion of the audit by the auditing organization. Responsibility for the evaluation program has been assigned to the Manager, Quality Assurance. Audits are conducted or coordinated by Quality Assurance personnel and shall include evaluation and examination of the following quality-related activities:

Justification - Clarify the distribution requirements for audit reports.

LDCR-SA-2011-1, EV-CR-2010-003005-5 (TJEW):

The FSAR will be revised to reflect the disconnection and abandonment of pressurizer heater elements #19, #20, and #45 and the corresponding reduction in heating capacity from 1800 kW to 1731 kW. This activity has no impact on the pressurizer design function as the minimum heater requirements are not affected.

On Table 5.1-1B (Unit 2) Sheet 1, revise the Pressurizer heater capacity, (kW) from 1,800 to 1,731.

FSAR Amendment 104

LDCR-SA-2010-18, EV-CR-2010-006120-13 (RAS):

Added the following sentence to the end of item #5:

"To prevent any adverse impact on controls at the HSP or local control stations when Control Room is evacuated due to a fire, the surveillance test program validates the opening of isolation contacts for transfer switches used to transfer controls in the event of a control room fire."

Clarifies surveillance testing requirements for controls used for shutdown from outside the Control Room.

Added note "(d)" to HS-4524FL and CS-BT-1EB13L

Added note "(d)" to HS-2452C

Added note "(b)" to HS-2452B

LDCR-SA-2009-14, EV-CR-2008-001609-00-11 (SCD):

Revise section 6.3.2.2.9.2 of the FSAR to include description of the new replacement SI to CL check valves (1/2SI-8819D). The replacement check valves are a nozzle style check as opposed to the currently described spring loaded, lift piston types for sizes 2" and smaller in the Emergency Core Cooling System.

LDCR-SA-2011-8, EV-CR-2010-011041-2 (SCD):

Insert the following prior to the last sentence in the second paragraph in section 11.4.2.7:

"Interim storage locations include a warehouse area (2K7) and a fenced area (3L15) shown in Figure 1.2-1."

The existing FSAR description does not reflect locations of interim radioactive material/ waste storage areas at CPNPP.

Revise Figure 1.2-1 to add a label for the Interim Radioactive Waster Storage Area 3L15.

LDCR-SA-2010-20, EV-CR-2010-008660-2 (TJD):

Correct description of PORV Tubing (between piping and PORV) and note that it applies to Unit 1 only. This change is required by regulation to match the as-built plant as shown on FSAR Figure 6.3-1 (M1-0262 sh. – and M2-0263-B). In this case, the Nitrogen Accumulators are inside a Code N-5 Boundary (i.e., are Code Class 3). Note 41 is only applicable to the tubing for Unit 1.

LDCR-SA-2010-20, EV-CR-2010-008660-2 (TJD (continued):

Correct the line item for CCW air accumulators (as shown on FSAR Figure 9.3-3) to be consistent with all the other air accumulators and associated check valves and tubing as shown on FSAR Figure 9.3-1). As shown on the flow diagram, these accumulators are installed in the instrument air tubing system. This tubing was designed and installed in accordance with CPES-I-1018 and Table 17A-1 Note 41. Because they were installed in a tubing system, the check valves and accumulators were not included in an N-5 Code boundary. In accordance with T17A-1, Note 40, the Code Class must be "-".

Revise Reference FSAR Sections for Air Accumulators from Section 10.3 to Section 9.3.1 for consistency.

Revise Reference FSAR Sections for Tubing and supports from Section 9.3.1 to Section 3.9B for consistency.

Add Reference to FSAR Section 9.3.1 for Air Accumulators for consistency. Revise Reference FSAR Section for Tubing and supports from Section 9.3.1 to Section 3.9B for consistency.

Fix typographical error in Note 40. - "_" should be "-".

LDCR-SA-2008-21, EV-CR-2008-001221-00-12 (JCH):

Description of Change: Update FSAR to reflect radial arm hoist assembly (RAHA) QA Requirements.

Table 17A-1 Sheet 35 of 58: Changed Stud tensioner Handling Device to Radial Arm Hoist Assembly.

Table 17A-1 Sheet 58 of 58: Added Not 93.

Technical Justification:

FDA-2008-001221-04 is changing Unit 2 RAHAs to have quick disconnects for the hoists, similar to Unit 1. It also documents the current plan to remove the radial arms in Modes 1 - 4. The FSAR update is required to update the Q List for the pre-OL change from a Stud Tensioner Handling Device, which was a simple hoist, to the Radial Arm Hoist Assembly. The change is administrative and is required to document the applicable quality assurance requirements. Upgrade of the RAHA design to seismic Category II had been found impractical.

LDCR-SA-2010-5, EV-CR-2006-003080-00-320 (JDS):

Include reference in the discussion of Regulatory Guide 1.126 to reflect the vendor model for Westinghouse methods for the analysis of fuel densification used after the transition to the Westinghouse methodologies.

LDCR-SA-2010-5, EV-CR-2006-003080-00-320 (JDS) (continued):

Add reference 12, the Westinghouse method (WCAP-8219-A) for the analysis of fuel densification used after the transition to the Westinghouse methodologies.

Remove reference 18 to Regulatory Guide 1.126, the Westinghouse method (WCAP-8219-A) for the analysis of fuel densification is used after the transition to the Westinghouse methodologies.

LDCR-SA-2010-8, EV-CR-2007-003164-00-3 (JDS):

Update title from "Fuel Handling Maching" to "Fuel Handling Bridge Crane" for consistency with other sections of the FSAR.

The changes are two electric trolleys hoist (one on East side and other one on West side) on an overhead structure instead of one electric trolley hoist. The hoist speeds are limited to 3 feet per minute in the slow zone and 21 feet per minute in the fast zone. For text of the change see attachment below. These changes reflect the current configuration of the new replacement Fuel Handling Bridge Crane.

In addition, the description of the features of this new crane (including speeds and automatic features) are included in the text.

This change identifies the code required ASME NUM-1 (Type B) for hoisting equipment and ASME NOG-1 (Type II) for trolley and crane structure for the design and construction of the new fuel handling bridge crane. For text of change see attachment below. The codes invoked encompass the requirements of CMAA-70 and include requirements typically recognized within the Nuclear Industry. Further, ASME NUM-1 and ASME NOG-1 codes apply to cranes operating in Nuclear Power Plant.

Item 33 of this Table:

Delete non-IEEE-383 cable and its PVC insulation associated with the fuel handling bridge crane anticrabbing control and computer control cables to the fuel handling bridge crane anticrabbing control TCS device. The anticrabbing control for existing crane will be removed along with the crane, since these will not be required for the new replacement crane.

LDCR-SA-2011-5, EV-CR-2009-000859-00-15 (JDS):

Changes to Quality Assurance section of FSAR to support implemtation of the Dry Cask Storage System to include the Independent Spent Fuel Storage Installation (ISFSI) facility, activities supporting spent fuel dry cask loading, and the associated dry cask storage equipment.

FSAR Amendment 104

LDCR-SA-2010-16, EV-CR-2010-008336-3(JCH):

Section 9.5.2 Communication Systems

Description: Update the FSAR to replace Private Automatic Branch Exchange(PABX) Telephone with Intraplant(IP) Telephone System in Section 9.5.2.

Page 9.5-71 Section 9.5.2.1 Change private automatic branch exchange (PABX) to Intraplant (IP).

Page 9.5-72 Section 9.5.2.2.2 Change PABX to IP.

Page 9.5-73 Section 9.5.2.2.5 Add IP and delete (PABX telephone system).

Page 9.5-74 Sections 9.5.2.2.7 and 9.5.2.2.10 Change PABX to IP.

Page 9.5-75 Section 9.5.2.2.10 Change PABX to IP.

Justification:

Administrative change by standardizing the name of Intraplant (IP) Telephone System used within FSAR which creates less confusion when telephone technology changes.

LDCR-SA-2011-3, EV-CR-2010-010560-2(SCD):

Update CPNPP management resumes and position descriptions.

LDCR-SA-2010-17, EV-CR-2009-002851-00-4(TJEW):

This activity does not provide a relaxation in the technical or maintenance requirements used when a Mild or Harsh equipment designation is applied. The FSAR is being revised to ensure that components installed within potentially harsh environments are consistently identified as harsh. It has no adverse impact and does not affect the safe shutdown capability of the plant, nuclear safety, industrial safety, plant, system or component reliability. No new test or experiments not described in the LBDs are associated with this activity.

Two CDF were identified as needing revision (22835 and 25701)

On page 3.11B-2,

1.) delete the second paragraph of the note under section 3 that reads,

"If radiation is the only harsh environment criterion exceeded for an area and an evaluation concludes that the component materials for a piece of equipment has a radiation threshold level greater than the postulated radiation environment, then, for purposes of environmental qualification, the equipment will be considered to be located in

LDCR-SA-2010-17, EV-CR-2009-002851-00-4(TJEW) (continued):

a mild environment. The radiation threshold level is the lowest radiation exposure at which property changes in component material is documented. Such documentation can be from materials handbooks, textbooks, government reports, laboratory data, and industry sources."

and

2.)delete the note in section 4 that reads,

"If relative humidity is the only harsh environment parameter exceeded for an area and an evaluation concludes that the subject equipment can perform its safety-related function(s) when exposed to the postulated relative humidity environment, then, for purposes of environmental qualification, the equipment will be considered to be located in a mild environment."

LDCR-SA-2009-4, EV-CR-2010-006971-17 (TJEW):

The installation of transfer panels will facilitate the connection of XST2A or XST2 to the 1E busses within the 72 hour LCO.

Revise transformer name from XST1/2 to XST2A in Figure 1.2-1.

In 8.2-10, revise transformer name from XST1/2 to XST2A on page 8-iv.

Revise transformer name from XST1/2 to XST2A on page 8.2-1.

Replact the paragraph on page 8.2-2 that reads,

"A spare startup transformer, XST1/2 with dual primary windings (345-kV and 138-kV), is stored in a dedicated location under the 345-kV line to XST2 (refer to Figure 8.2-1). This transformer must be physically relocated to replace XST2 or XST1 if required. This transformer is provided to prevent an extended interruption of offsite power in case of failure of any startup transformer."

with a paragraph that will read,

Spare startup transformer XST2A, with dual primary windings (345-kV and 138-kV), is in a dedicated location under the 345 kV line to XST2 (refer to Figure 8.2-1) to serve as a replacement of XST2. Cable buses from secondary X and Y windings of XST2 and XST2A are connected to two 6.9 kV transfer panels to provide 345 kV offsite power to Units 1 or 2 safety related buses. These transfer panels allow transfer of the 345 kV offsite power source for safety related buses from XST2 to XST2A and vice verse. This

LDCR-SA-2009-4, EV-CR-2010-006971-17 (TJEW) (continued):

spare transformer may be physically relocated to a dedicated location near XST1, to serve as a replacement of XST1.

In Figure 8.2-1,

1. revise the 345 transformer storage location name from "XST1/2" to " XST2A"

2. revise the 138 transformer storage location name from "XST1/2" to " XST1A"

3. correct the orientation and delete the extra transformer figure that does not exist next to 2ST

In Figure 8.2-4,

1. revise transformer name from XST1/2 to XST2A

2. swap name tags between XST2A and 1ST.

3. show a connection of 1ST to the non-safeguards buses and shorten the line representing the non-safeguards busses

4. revise the connections of XST2 and XST2A to show connection to the Transfer Panels

5. show the connection from the Transfer Panels to the 6.9 kV buses

6. relocate the "6.9KV SAFEGUARD BUSES (SEE FIGURE 8.3-1)" below the Transfer Panels

In Figure 8.2-5, Sheet 1, revise transformer name from XST1/2 to XST2A.

In Figure 8.2-10, Sheet 1,

1.) revise transformer name from XST1/2 to XST2A for the motor operarted switch, on the spare transformer, and on the Figure title

2.) add the new cable trench and cable bus from XST2A to the turbine building wall,

3.) Deleted "Amendment 100".

In Figure 8.2-10, Sheet 2,

1.) revise transformer name from XST1/2 to XST2A for the motor operated switch, transformer, and Figure title,

2.) Show the new cable trench and cable bus to the turbine building wall, and

LDCR-SA-2009-4, EV-CR-2010-006971-17 (TJEW) (continued):

3.) Deleted "Amendment 100".

In Figure 8.2-11,

1, revise transformer name from XST1/2 to XST2A

2, show the cable trench to from XST2 and XST2A to the Transfer Panels and to the 6.9kV buses.

In Table 8.3-3 Sheet 2,

1.) In "Item 4", under the "Function" column, add the words "through CPX-EPTSST-02Y" after Unit 1 and add the words

"through CPX-EPTSST-02X" after Unit 2.

2.) In "Item 4A", under the "Fuction" column, replace the words that read "buses 1EA1 and 1EA2 of Unit 1" with the words "transfer panel CPX-EPTSST-02Y".

3.) Under the "Effects on System" column, add the following words at the end of "Item 4" and "Item 4A", "Can also realign to spare startup transformer XST2A (Item 4C).

On Table 8.3-3, Sheet 3,

1.) In the "Function" column replace the words that say, "XST2 to buses 2EA1 and 2EA2" with the words "transfer panel CPX-EPTSST-02X from XST2",

2.) Add the words, "Can also realign to spare startup transformer XST2A (Item 4C)"

3.) Add the Failure Mode and Effect Analysis "4C" for the "Spare Startup transformer XST2A", "4D" for the "15-KV Cable" Y-winding connection, and "4E" for the X-winding connection.

In 9.5.1.5.6,

1. In the sentence that reads,

"The unit auxiliary transformer and the Unit 1 startup transformer are separated from the Turbine Buildings by a three-hr rated fire wall."

Delete the words "Unit 1" and after word "transformer" insert the words, "s XST1 and XST2"

2. Delete the sentence that reads,

LDCR-SA-2009-4, EV-CR-2010-006971-17 (TJEW) (continued):

"The Unit 2 startup transformer is also separated from the Turbine Building by a three-hr rated fire wall."

3. In the last sentence that reads,

" The Unit 1 station service transformer is separated from the Turbine Building by a distance greater than 50 feet."

Delete the words "The Unit 1", capitalize the "s" in station, and insert the following words after "transformer"

"s 1ST and 2ST and spare transformer XST2A are" and

delete the word "is"

On Figure 10.2-1 add "\XST2A" after XST2 in three locations.

LDCR-SA-2011-6, EV-CR-2009-000859-00-16 (JDS):

Include a description of the Independent Spent Fuel Storage Installation for the facility desciption for completeness.

Revise drawing to show location of the Independent Spent Fuel Storage Installation.

Update Table of Contents to reflect new section for Spenf Fuel Dry Cask Storage and clarify that section 9.1.2 is Spent fuel storage in the spent fuel pools and containment.

Update title to include description of spent fuel storage in "the spent fuel pools and containments."

Update text to refer to heavy load of the Holtec Hi-Trac tansfer cask for the Fuel building overhead crane.

Insert new section 9.1.5 to describe the independent spent fuel storage installation and the specific Certificate of Compliance (1014) used for dry cask storage.

Add an additional three references for the Cask FSAR, the Holtec Certificate of Compliance (1014) and the NUREG-6407 for Transportation and packaging of spent fuel.

Add reference to the Fire Hazards Analysis for ISFSI and Haul Path to the ISFSI.

Include reference to the CPNPP 10CFR72.212 Evaluation report.

Include statement for a fully loaded (84 Casks) bounding annual exposure for the ISFSI in the estimated annual dose at the exclusion boundary and to the population at large.

FSAR Amendment 104

LDCR-SA-2011-12, EV-CR-2010-008829-2 (TJEW):

On Figure 9.5-52 (M1-0215), Sheet F:

1.) add note 10 that says, "10. Alternate fill location connection point. Box with Access Cover Plate is maintained watertight"

2.) On the truck fill watertight valve box add "COVER" in between "REMOVABLE" AND "PLATE"

3.) add an arrow with a note that says "See Note 10" at the quick disconnect fitting

4.) at the quick disconnect fitting add "COVER" in between "REMOVABLE" AND "PLATE"

5.) add the removable access cover plate and add an arrow pointing to the removable access cover plate and the note that says, "REMOVABLE ACCESS COVER PLATE"

On Figure 9.5-52 (M2-0215), Sheet F:

1.) add note 12 that says, "12. Alternate fill location connection point. Box with Access Cover Plate is maintained watertight"

2.) On the truck fill watertight valve box add "COVER" in between "REMOVABLE" AND "PLATE"

3.) add an arrow with a note that says "See Note 12" at the quick disconnect fitting

4.) at the quick disconnect fitting add "COVER" in between "REMOVABLE" AND "PLATE"

5.) add the removable access cover plate and add an arrow pointing to the removable access cover plate and the note that says, "REMOVABLE ACCESS COVER PLATE"

On Figure 9.5-52 (M1-0215), Sheet G:

1.) add note 10 that says, "10. Alternate fill location connection point. Box with Access Cover Plate is maintained watertight"

2.) On the truck fill watertight valve box add "COVER" in between "REMOVABLE" AND "PLATE"

3.) add an arrow with a note that says "See Note 10" at the quick disconnect fitting

4.) at the quick disconnect fitting add "COVER" in between "REMOVABLE" AND "PLATE"

5.) add the removable access cover plate and add an arrow pointing to the removable access cover plate and the note that says, "REMOVABLE ACCESS COVER PLATE"

LDCR-SA-2011-12, EV-CR-2010-008829-2 (TJEW) (continued):

On Figure 9.5-52 (M2-0215), Sheet G:

1.) add note 12 that says, "12. Alternate fill location connection point. Box with Access Cover Plate is maintained watertight"

2.) On the truck fill watertight valve box add "COVER" in between "REMOVABLE" AND "PLATE"

3.) add an arrow with a note that says "See Note 12" at the quick disconnect fitting

4.) at the quick disconnect fitting add "COVER" in between "REMOVABLE" AND "PLATE"

5.) add the removable access cover plate and add an arrow pointing to the removable access cover plate and the note that says, "REMOVABLE ACCESS COVER PLATE"

On page 9.5-81, Section 9.5.4.2.1 add the following words to:

1.) at the end of the first sentence of the forth paragraph add, "or via an alternate fill method which utilizes a special diffuser tool to fill through the Sample Grab Point quick-disconnect fitting connection, which is also in a watertight box." and

2.) After the third sentence of the fourth paragraph add the sentence, " When the alternate fill method is used, the special diffuser tool is also capped at the bottom and perforated with holes."

On figure 9.5-51,

1.) add note 1 that says, "Note 1. Sample Grab Point Connection provides additional truck fill method via use of special diffuser tool. This box is maintained watertight." in the lower left hand corner and

2.) add an arrow pointing at the Sample Gab Point Connection and a text box that says, "See Note 1"

LDCR-SA-2010-19, EV-CR-2010-010870-1 (TJEW):

On page 10.4 page 33, third paragraph, replace the word "each" with "Unit 2" and add a "s" after the first occurrence of the word "generator".

LDCR-SA-2009-20, EV-CR-2009-005301-7 (TJEW):

Justification: Changes to the description of the 345 kV Switchyard are required for addition of two breakers and their associated lines (Everman & Parker 2) and relocation of the TO's breaker controls/protection to TO's control building. With the new relay control panels a third set of protective relays are not required for line breakers. Therefore, the lines will only have primary or secondary (backup) sets. In addition, the

LDCR-SA-2009-20, EV-CR-2009-005301-7 (TJEW) (continued):

FSAR and associated Figures are being revised to reflect name changes of TXU Electric Delivery to Transmission Operator (TO) in the affected sections. Further, the approximated length of transmission lines to the substations connected to the CPNPP Switchyards is deleted, because this detail is not required for the FSAR. Also the discussion of transmission towers on pages 8.2-3 and 8.3-4 is being deleted from the FSAR because the information is shown in Figure 8.2-12. Section 8.2.2 analysis is updated to reflect the impact of loss of double circuit towers as a result of addition of new lines. In addition Oncor has reviewed the the section 8.2.2 analysis for its adequacy due to the addition of new lines.

On Page 1.2-9, second paragraph, section 1.2.2.5

1.) change "five" to "seven" and

2.) In the same paragraph, change "owner's" to "Transmission Operator's"

On Page 8.1-1,

1.) Update the Utility Grid Description to reflect the changes in the ERCOT organization.

2.) change all of "TXU Electric Delivery" to "TO"

On Page 8.2-1, change

1.) all of "TXU Electric Delivery" to "TO" and

2.) the reference to "five" 345kV transmission lines to "seven" lines and

3.) In the third paragraph, add the word system before the words "as shown on Figure 8.2-4"

4.) Add the following sentence, from page 8.2-3, to the end of the third paragraph, "The 138-kV switchyard is physically and electrically independent of the 345-kV switchyard."

On Page 8.2-2,

1.) In the 4th paragraph, delete the words that say, "The network transmission line terminals of 345-kV switchyard are provided with a third set of relay protection to enhance the reliability of transmission system fault isolation."

2.) In the 5th paragraph, delete the words that say, "A separate 125-VDC system is provided for the third set of relay protection in the 345-kV switchyard."

3.) In the 6th paragraph,

LDCR-SA-2009-20, EV-CR-2009-005301-7 (TJEW) (continued):

a.) add the following words, "The 345-
kV switchyard TO circuit breakers may be operated from either the 345-
kV Switchyard Control Building or remotely from TO's System Operations Center."

b.) In the next sentence change the word "all" to "CPNPP", delete the words "the spare", and add the word XST2A after transformer.

c.) In the next sentence capitalize the first letters in the following words, "switchyard relay house", add "138-kV" before the words

"switchyard relay house", and replace the words "through TXU Electric Delivery" with "from TO".

4.) In the 8th paragraph,

a.) delete the words, "and the approximate length of their respective transmission lines", rearrange the list of tranmission lines to match , as shown below, the switchyard Figure 8.2-4, and delete the transmissison line lengths.

"* DeCordova (138-kV)

* Stephenville (138-kV)

* DeCordova (345-kV)

* Wolf Hollow (345-kV)

* Everman (345-kV)

* Johnson Switch (345-kV)

* Comanche Switch (345-kV)

* Parker No. 1 (345-kV)

* Parker No. 2 (345-kV)"

On page 8.2-3,

1.) The order of the CPNPP transmission lines, including the Stephenville line, will be revised as shown on Page 8.2-2 and therefore, the Stephenville line detail on the first line of this page will be deleted.

2.) Insert the following words before the first paragraph,

FSAR Amendment 104

LDCR-SA-2009-20, EV-CR-2009-005301-7 (TJEW)(continued):

"The layout of transmission lines from TO's CPNPP switchyards to other switching stations, in the vicinity of CPNPP switchyards, is shown in Figure 8.2-12.

The following combinations of lines form double-circuits routed on common transmission towers:

345-kV Parker No. 1 and 345-kV Parker No. 2

345-kV Comanche Switch and 138-kV Stephenville

345-kV Everman and 345-kV Johnson Switch

345-kV DeCordova and 345-kV Wolf Hollow

3.) Delete the next 6 paragraphs.

4.) In the 7th paragraph,

a.) delete, the 1st sentence,

b.) in the 2nd paragraph, add "138-kV" after "The".

c.) delete the third sentence.

5.) In the 8th paragraph,

a.) Delete the first sentence,

b.) in the second sentence, replace "The line then" with "The 138-kV line to Stephenville", add "Everman," after "Wolf Hollow", and replace "Venus before making another 90° turn" with "Johnson Switch".

c.) Delete the 3rd sentence.

On page 8.2-4, delete the words from the paragraph that started on page 8.2-3, "Upon making the second turn, the line then shares common towers with the 345-kV line to Comanche Switch."

On Page 8.2-5, change all of "TXU Electric Delivery" and "TDSP" to "TO".

On page 8.2-7,

1.) second paragraph of section 8.2.2,

a.) add a comma in the first sentence after the words "Comanche Switch line"

LDCR-SA-2009-20, EV-CR-2009-005301-7 (TJEW) (continued):

b.) in the two places where "Parker Line" is written, before the word "line" insert, "No. 1 and Parker No. 2 double-circuit", in the three places where the word "Venus" is written, replace it with "Everman and Johnson Switch double-circuit", add the word "the" before the second occurrence of "Venus"

c.) In the 4th sentence, add a "-" between "double" and "circuit"

2.) In the third paragraph of section 8.2.2

a.) delete the words "Electric Reliability Council of Texas" and the "()" around ERCOT

b.)change "TXU Electric Delivery" to "TO"

On Page 8.2-8,

1.) change "TXU Electric Delivery" and "TXU Delivery" to "TO".

2.) Delete the entire 7th paragraph.

On Page 8.2-9,

a.) change all of "TXU Electric Delivery" to "TO".

B.) Replace the words, "There are no restrictive operating limits (real and reactive power, voltage, frequency and other) established for CPSES by ERCOT. However, CPSES requires that TXU Electric Delivery transmission" with "In order to satisfy offsite power requirements, the TO should"

On Page 8.3-2, second paragraph, change

1.) "TXU" to "TO" and

2.) the reference to "five" 345kV transmission lines to "seven" lines

Revise Figure 8.2-1 to show the new 345 kV Parker and Everman Lines, delineate the Parker No. 1 and No. 2 lines, add the TO Control Building, and change the Venus line to Johnson Switch.

Revise Figure 8.2-4 to show the new 345 kV Parker and Everman Lines and Breakers at both ends of the lines, delineate the Parker No. 1 and No. 2 lines, change TXU Energy Delivery to TO, change the Venus line to Johnson Switch, and revise the breaker arrangement at Johnson Switch and Wolf Hollow.

Revise Figure 8.2-5, sheet 1 to show

1.) to show the new Oncor Control Building

LDCR-SA-2009-20, EV-CR-2009-005301-7 (TJEW) (continued):

2.) the new West Bus, Bay 9 Breaker for the Parker No. 2 transmission line

Revise Figure 8.2-5, sheet 2 to show

1.) change "Venus" to "Johnson Switch"

2.) the addition the new 345 kV Everman Line Breaker and associated equipment on the East Bus of bay 4, change the Venus line to Johnson Switch

Revise Figure 8.2-12 to show

1.) the new 345 kV Parker and Everman Lines,

2.) delineate the Parker No. 1 and No. 2 lines,

3.) change the Venus line to Johnson Switch.

LDCR-SA-2010-1, EV-CR-2006-003080-44 (SCD):

The changes made to FSAR Section 11 reflect the change in isotopic inventory associated with the increase in power as well as the transition from historical TXU calculation methodologies to those of Westinghouse.

The changes made to FSAR section 12 reflect the revised dose estimations associated with normal operations and assuming the revised isotopic inventory. Note dose assessments associated with accident conditions, i.e., FSAR Chapter 15 events, were performed by Westinghouse and are outside of the scope of this LDCR.

FSAR Amendment 104a

LDCR-SA-2010-14, EV-CR-2007-003115-00-12 (GLM):

The FSAR is being revised because the existing clarifier based pre-treatment subsystem portion of the Water Treatment (WT) System has deteriorated due to the aggressive nature of the lake water and chemicals required for treatment. The pre-treatment subsystem portion of the WT System is being replaced using current microfiltration technology.

With this modification, the clarifier is being taken out of service and replaced with microfiltration units. Therefore, changes to the system description are required, which maintains the design requirements. This modification removes the clarifier, pressure filters, and filtered water forwarding pumps from the WT System and replaces it with microfiltration units. These units are a membrane based filtration system which removes suspended solids and achieves water quality requirements in a one-step filtration process. The system includes filtration tanks, pump skid, module skid, and a clean-in-place (CIP) skid. These changes reflect the new equipment being installed and maintain the design requirements.

LDCR-SA-2011-13, EV-CR-2010-000979-15 (JDS):

Delete TM symbol from Zirlo as this a Registered tradmark. Zirlo is now used to refer to this type of cladding material.

Add rod bow penalty WCAPs (8691 and 8692) to the material incorporated bny reference. Text added to chapter 4 describes this as the accepatable methodology for use to calculate rod bow penalty.

Include the discussion of the use of the Standardized Debris Filter Bottom Nozzle (SDFBN) and the Robust Protective Grid (RPG). These fuel assembly components are now characteristic for reloads at CPNPP.

Update Minimum DNBR for design transients to reflect appropriate values based on WRB correlation used. Update the Average mass velocity for correct description for the values provided. Update maximum overpower value used for Peak linear power resulting from overpower transients/operator errors. Insert RPG for robust p grid usage.

Include the discussion of the use of the Robust Protective Grid (RPG). This fuel assembly components is now characteristic for reloads at CPNPP.

Provide a description of the Standardized Debris Filter Bottom Nozzle (SDFBN) for Westinghouse 17x17 fuel. This design is now standard for reloads for CPNPP units 1 and 2.

Provide a description of the Westinghouse Robust Protective Grid (RPG) design. This design is now standard for reloads for CPNPP units 1 and 2.

Clarify use of nomenclature used for Westinghouse fuel for the Vantage+ fuel design.

LDCR-SA-2011-13, EV-CR-2010-000979-15 (JDS) (continued):

Update discussion on Effects of Rod Bow on DNBR to reflect NRC approved methodology.

Include reference to Effects of Rod Bow on DNBR approval by the NRC (WCAP 8691 and 8692)

Update maximum overpower value used for Peak linear power resulting from overpower transients/operator errors.

LDCR-SA-2011-14, EV-CR-2011-001279-1 (JDS):

Update 7 minutes 30 seconds to 8 minutes and 13 minutes to 14 minutes for consistency with previous statement on this same page and the supporting analysis.

LDCR-SA-2011-2, EV-CR-2009-001766-00-4 (RAS):

Add the following to the end of the sentence for item 'b.' under "Testing of Reactor Trip Breakers":

"...or by a Reactor Trip Test pushbutton via a keylocked test selector switch."

LDCR-SA-2009-22, EV-CR-2007-000293-00-1 (TJD):

FSAR section 17.2.15 is being changed to utilize a conditional release to not only install the nonconforming component in the plant but also to declare the affected SSC Operable per Technical Specifications (TS), provided that resolution of the nonconforming condition is tracked in the Corrective Action Program (CAP), and an evaluation of the nonconforming condition shows that it does not adversely affect Operability of the component. This change was approved by the NRC in a Safety Evaluation dated 9/23/11.

Revise item 5 as follows:

Conditional releases allow issuance of nonconforming items from the warehouse for installation, testing, and operation, pending disposition of the nonconformance. For nonconforming items installed with a conditional release, and affecting Technical Specifications, credit may be taken for Technical Specification operability of the item, provided that: a) resolution of the nonconforming condition is tracked, and b) evaluation of the nonconforming condition supports operability of the component. Each conditional release also describes any limitations or special precautions required. Conditional releases are periodically evaluated as to their status and the results forwarded to management for their review.

FSAR Amendment 104a

LDCR-SA-2011-15, EV-CR-2008-003340-00-6 (TJEW):

Table 3A.3-2, Sheet 5, section 1.3, is changed via FDA-2008-003340 and in the FSAR via LDCR SA-2011-015 in EV-CR-2008-003340-6 to revise boron concentration from '2200' to '2600' and from "initial" to "final" spray solution to (1) align configuration control and (2) correct the statement so that it is understood that short period exposure to out of specification ph chemical spray will have no effect on the ability of equipment inside containment to perform their safety function.

LDCR-SA-2009-18, EV-CR-2009-001588-00-31 (TJEW):

Technical Justification:

Issue 1 - FSAR Table 7.5-7C note 21 and the response to the TMI Action Plan Section II.F.1 state that the "containment water level covers the entire range of expected water level in the containment for post-accident conditions." This statement regarding the wide range span and the requirement for a separate narrow range instrument was based on a misinterpretation of the maximum flood level calculation 525-00. The calc had conservatively assumed that the reactor cavity was not flooded to maximize the peak flood level. Based on Calculation 525 dated 3-23-1979, the range of containment flooding was calculated from El. 808 to El. 817'-6". Based on the current calculation NU(B)-057 R3, the range of flooding is from the El. 781'-2" rector cavity sump and El 783'-7" reactor cavity [see A1-0529] to the maximum flood El. 816'-10". The FSAR requires update and clarification.

Issue 2 - FSAR table 7.5-7E note 18 states "Containment Water level transmitters are multipoint sensors and failure of any one sensor would not cause ambiguity and hence will not have any adverse effect on the monitoring of containment water level." This statement was based on the assumption that the analog control board indicators for the original level instrumentation would be multipoint LEDs corresponding to the RTDs. However, the original 4-20 ma analog indicators were not replaced. The failure mode of the loop is such that the failure of one sensor can be read as one foot high or one foot low across the scale. This is an ambiguous failure. The FSAR requires update and clarification.

On page 7.5-10, in Section 7.5.2.1, replace "10. Containment Water Level" with the word "Deleted"

In Table 7.5-2, delete "Containment Water Level Key A1"

In Table 7.5-7A, Sheet 2 of 15, for the row containing "CONTAINMENT WATER LEVEL (NOTE 21), delete "A1" and add "-3"" after "808"'.

In Table 7.5-7C, Sheet 2 of 4, number 21, 1.) Insert the words "(from prior to the start of switchover from injection to recirculation to the maximum containment flood level)" between the words "level" and "in" and 2.) After the first sentence, insert the sentence, "The water level in the sump is assured by the RWST Low-Low level setpoint for the start of switchover. Operator action based on containment water level is not required."

LDCR-SA-2009-18, EV-CR-2009-001588-00-31 (TJEW) (continued):

In Table 7.5-7D, Sheet 1 of 7, and in the row of "Containment Water Level" add "-3"" after "808"'.

In Table 7.5-7E, Sheet 3 of 3, number (18), delete all the words after "transmitters" and add the following words, "were intended to be multipoint sensors which would prevent an ambiguous failure from occurring. The original indicators were never replaced, however, and the original analog indicators rely on an additive logic to compute the water level. This results in the potential for a failed indicator to cause a false reading of ± 1 foot. The containment water level indicators are for information only and will not adversely affect the ability to safely mitigate an accident."

In section 11.F.1, CPNPP Response (5) on page II.F-3, 1.) Add "-3"" after "808"' 2.) Add the words "the intent of" between "meeting" and "Regulatory" 3.) replace the words "entire range of expected water level in the Containment for post accident conditions" with the words, "maximum expected flooding levels assuming the reactor cavity is blocked and does not receive any flood water to simulate the most limiting post-accident condition (flooding starts at El. 808'). Actual post-accident conditions would include flooding into the reactor cavity sump (781' -2") and reactor cavity (783' - 7").

LDCR-SA-2011-18, EV-CR-2011-008509-4 (TJEW):

Revise FSAR Section 9.5.5.2 to reflect information in FSAR prior to issuance of LDCR-SA-2004-014 which changed the Jacket Water Heat Exchanger leakage rate. The justification for this change is that during the 2011 PI&R Inspection, a potential Severity Level IV violation of 10CFR50.59 was identified for an incorrect 50.59 screen related to changing the EDG jacket water leakage rates in the FSAR. The screen incorrectly concluded that an evaluation was not required.

On page 87 of sectio 9.5.5.2, 6th paragraph, change 408 gallons to 310, change 17 gallons per hour to 1.5, and change 24 hours to seven (7) days.

LDCR-SA-2011-21, EV-CR-2011-014200-1 (TJEW):

Components FT-6708 and FT-6709 are identified within DBD-EE-004 and FSAR Table 7.5-7B (Sheet 8 of 11) as being required to be seismically qualified. The devices are in fact only required to be seismically mounted. DBD-EE-004 section 4.3.2.1.1 states 'Category 2 instrumentation supplied from Non-1E power need not be seismically qualified unless it is part of a seismic Category I system and its failure may degrade this system.' The flow transmitters are N1E, Process Instruments(Isolable, Offline). DBD-ME-028, attachment 19, page 7 of 23, identifies that these types of transmitters are ANSI class: N/A, IEEE Class: N1E, Seismic Category: None, Safety Related: No, and EQ: No.

DBD-ME-028, Table 1, note 3, is associated with components identified as N1E, Process Instruments(Isolable, Offline). This note states that Seismic Category II mounting applies to the non-1E transmitter or gauge. This mounting requirement is identified within Maximo-MEL. The Location screen contains attribute 'CFC2'. For FT-6708 and FT-6709

FSAR Amendment 104a

LDCR-SA-2011-21, EV-CR-2011-014200-1 (TJEW) (continued):

the components are identified as SMTQ. The SMTQ designation identifies that the components require 'Seismic Integrity Evaluation and Mounting of Non-safety Related Instruments Connected to ANSI 2 or 3 Fluid Systems'.

Revise the note in Table 7.5-7B, Sheet 8 of 11, Variable - Safety Chilled Water Flow from "Note 5" to "Note 6"

LDCR-SA-2011-17, EV-CR-2011-003925-5 (JDS):

Reference Westinghouse Letter transmitting the GOTHIC containment pressure and temperature analyis for EQ.

Remove curves ad replace with methods. Reflects that the containment temperature and pressure curves used for EQ are no longer the same as those used for the containment integrity analysis.

LDCR-SA-2011-7, EV-CR-2009-000859-00-34 (JDS):

Update Table 3.7B-2 with newer versions of the ANSYS program. These versions of ANSYS were used for ancillary equipment used in the fuel building supporting the Dry Cask Storage project.

LDCR-SA-2011-16, EV-CR-2011-005954-4 (SCD):

Incorporate change of Quality Assurance (QA) to Nuclear Oversight.

FSAR Amendment 104b

LDCR-SA-2012-9, EV-CR-2011-012481-1 (RAS):

Revise the paragraph at the top of the page as follows to reflect the implementation of the Relaxed Axial Offset Control Methodology:

The axial flux difference deviation alarms are derived from the plant process computer which determines the 1 minute averages of the excore detector outputs to monitor delta flux in the reactor core and alerts the operator where delta flux alarm conditions exist. When power level is 50 percent or greater, an alarm message is output immediately upon determining a delta flux exceeding the Technical Specifications (this alarm requires 2 of the 4 AFD channels to exceed the power dependent limits). The signals from the four section excore detectors are summed and calibrated to a power measurement made using a secondary system calorimetric. The signals from the upper two sections and lower two sections are combined to give an upper flux and lower flux signal as shown in Figure 7.1-2. These upper and lower signals must be calibrated to agree with axial offset measurements derived from flux maps made using the movable incore system. The NIS provides both slope and zero-offset adjustments to achieve this calibration.

LDCR-SA-2012-7, EV-CR-2012-002362-1 (TJEW):

Background: During preparation of FDA-2011-000004-01, an error concerning Flow Diagram M2-0263, Sheet No. C, Safety Injection System Sheet 6 of 6, was found. It is not included in FSAR Figure 6.3-1. This flow diagram is part of the Safety Injection System and Containment Isolation System described in the FSAR Chapter 6 text and tables. Without it, FSAR Figure 6.3-1 is incomplete.

Non-conforming Condition: The Note block designating the drawing as part of FSAR Figure 6.3-1 is missing. Therefore, the Drawing was not included in the FSAR figure as required by RG 1.70 R2 and the FSAR is not current as required by10CFR50.71(e). The FSAR is not being update for changes to the facility as required by regulations (e.g. FDA-2008-003459-04). Corrective Action required: M2-0263 Sheet No. C must be revised and added to FSAR Figure 6.3-1 and to the Chapter 6 TOC.

Additionally, while performing a consistency review of the LDCR, found that FSAR Tables 3.2-3 and 3.2-4 also need to include M2-0263-C.

On Table 3.2-3, Sheet 10 fo 13, there is no entry for Unit 1; however, for Unit 2 add, "M2-0263-C CP-7 104* 6.3-1"

On Table 3.2-4, Sheet 1 of 16, there will be no entry for Unit 1; however, for Unit 2 add "6.3-1 M2-0263-C"

On page 6-xvii, the Table of "List of Figures" add ", M2-0263-C” at the end of the title for 6.3-1.

FSAR Amendment 104b

LDCR-SA-2012-11, EV-CR-2011-001492-12 (JCH):

Description: Revise Table 3.9N-10, "Unit 1 & 2 Active Valves," to include active relief valves 1-8121 and 2CS-8000.

Justification: RCP seal water return line relief valves, 1-8121 and 2CS-8000, are required to protect the excess letdown/seal water return header from overpressurization in the event that the line exiting containment is isolated while the excess letdown and/or the RCP No. 1 seal leakoff continues in service. The IST plan correctly designates these valves as active for Containment Penetration Overpressure Protection from both seal injection and thermal expansion however DBD-ME-255 Table 4-1 and FSAR Table 3.9N-10 show these valves as passive. This change will align the design and licensing basis documents to the IST plan. There is no change to the valve or its subcomponents and no change to the design function of the valve.

LDCR-SA-2012-10, EV-CR-2012-000999-1 (SCD):

Description of the Old Steam Generator Storage Facility was not adequately incorporated into the proper FSAR chapters.

LDCR-SA-2012-14, EV-CR-2011-008520-14 (SCD):

The Safe Shutdown Impound (SSI) is a thriving dynamic biological system with significant biological populations that can contribute to debris entering the Station Service Water (SSW) system. This debris can result from die-off of small fish (i.e. Threadfin Shad or Silver Sides), algae, live or dead Harris mud crabs and storm water runoff debris. Shad die-offs have occurred in the SSI that caused challenges to the SSW system safety related strainers. The SSI communicates with Squaw Creek Reservoir (SCR), which allows exchange of fish species and complicates measures to reduce or control fish populations. The installed floating booms minimize the ability of floating debris to enter the SSW system while the equalization canal net minimizes the migration of fish from SCR into the SSI.

Clarification is required on the limitation of use of the stop gates as a sole source of flood protection of the Turbine Building when the Circulating Water System is opened for maintenance. Due to the access opening in the operating deck of the circ-water discharge structure, the stop gates only isolate the CW Tunnels and any open CW system when the lake level is below 778 feet. As a result, any open CW system at elevation below the PMF level of 789.7 feet must be reassembled/closed or isolated when the lake level is on a rise and evident that it will reach/exceed a level of 778 feet. This ensures the isolation of the lake levels above 778 from the open pathway that could lead to flooding of the Turbine Building and lower level of the Electrical & Control Building on Elevation 778.

FSAR Amendment 104b

LDCR-SA-2010-3, EV-CR-2010-000528-8 (TJEW):

On page 1A(B)-55, in note a at the bottom of the page, change "0.8348" to "0.8299" and "38" to "39"

In 1A(B) on page 56, Part 9.C.2.a, change "0.8348" to "0.8299" and "38" to "39"

On page 9.5-82, change "0.8348" to "0.8299" and "38" to "39"

On page 9.5-83, change "0.8348" to "0.8299" and "38" to "39"

On page 9.5-86, change "0.8348" to "0.8299" and "38" to "39"

LDCR-SA-2012-17, EV-CR-2011-008700-17 (SCD):

Clarification is required on the limitation of use of the stop gates as a sole source of flood protection of the Turbine Building when the Circulating Water System is opened for maintenance. Due to the access opening in the operating deck of the circ-water discharge structure, the stop gates only isolate the CW Tunnels and any open CW system when the lake level is below 778 feet. As a result, any open CW system at elevation below the PMF level of 789.7 feet must be reassembled/closed or isolated when the lake level is on a rise and evident that it will reach/exceed a level of 778 feet. This ensures the isolation of the lake levels above 778 from the open pathway that could lead to flooding of the Turbine Building and lower level of the Electrical & Control Building on Elevation 778.

LDCR-SA-2012-15, EV-CR-2010-011195-4 (SCD):

10CFR50.71(e) requires the FSAR to be maintained current. This is an administrative update to the FSAR.

The FSAR 1A(B) exceptions to Revision 1 of RG 1.52 were reconciled with the RG and FSAR Table 6.5-1.

This Appendix 1A(B) discussion of RG 1.197 was not correct. It stated the TSTF incorporates the specific aspects of the RG whereas the TSTF took exception to specific aspects of RG1.197. This error was made at some point after LA 136.

The following are CPNPP exceptions to Sections C and C.1.2 of RG 1.197 documented in TS 5.5.20 which are not reflected in FSAR Appendix 1A(B):

1. C. - Section 4.3.2 “Periodic CRH Assessment” from NEI 99-03 Revision 1 will be used as input to a site specific Self Assessment procedure.

LDCR-SA-2012-15, EV-CR-2010-011195-4 (SCD) (continued):

2. C.1.2 - No peer reviews are required to be performed.

This Appendix 1A(B) discussion of RG 1.197 was not correct. It stated the TSTF incorporates the specific aspects of the RG whereas the TSTF took exception to specific aspects of RG1.197. This error was made at some point after LA 136.

The following are CPNPP exceptions to Sections C and C.1.2 of RG 1.197 documented in TS 5.5.20 which are not reflected in FSAR Appendix 1A(B):

1. C. - Section 4.3.2 “Periodic CRH Assessment” from NEI 99-03 Revision 1 will be used as input to a site specific Self Assessment procedure.

2. C.1.2 - No peer reviews are required to be performed.

The FSAR 1A(B) exceptions to Revision 1 of RG 1.52 were reconciled with the RG and FSAR Table 6.5-1.

LDCR-SA-2011-11, EV-CR-2009-001966-11 (GLM):

In the first sentence of Section 9.4C.6, "OFFICE AND SERVICE AREA HVAC SYSTEM" delete the words "...and relative humidity." In the first sentence, second paragraph of Section 9.4C.6, "OFFICE AND SERVICE AREA HVAC SYSTEM" change "air conditioning units" to "air handling units." Delete the second sentence, second paragraph of Section 9.4C.6, "OFFICE AND SERVICE AREA HVAC SYSTEM." In the third sentence, second paragraph of Section 9.4C.6, "OFFICE AND SERVICE AREA HVAC SYSTEM" change " direct expansion refrigerant cooling coil" to "chilled water cooling coil" and delete the word "humidifier."

The replacement air handling units are rated to provide a level of cooling which exceeds the rated capacity of the previous split air-conditioners (109.4 tons versus 94.5 tons) therefore this change does not adversely impact any design function of the Office and Service Area system, and the resulting changes to the FSAR are required to maintain configuration control. The humidifier does not perform or support a safety-related function for the O&SA HVAC system, therefore this change is not adverse. These changes do not adversely impact the O&SA HVAC system design function which is to provide a comfortable environment for operating personnel by maintaining the temperature and humidity as indicated by UFSAR Table 9.4-2.

For the Office and Service Area A/C, change the Relative Humidity (%) from "35-50" to (b).

The replacement air handling units are rated to provide a level of cooling which exceeds the rated capacity of the previous split air-conditioners (109.4 tons versus 94.5 tons) therefore this change does not adversely impact any design function of the Office and Service Area system, and the resulting changes to the FSAR are required to maintain configuration control. The humidifier does not perform or support a safety-related function for the O&SA HVAC system, therefore this change is not adverse. These changes do not adversely impact the O&SA HVAC system design function which is to provide a comfortable environment for operating personnel by maintaining the temperature and humidity as indicated by UFSAR Table 9.4-2.

LDCR-SA-2011-19, EV-CR-2009-001930-5 (GLM):

Revise the last sentence to state that the potable water supply is from the Somervell Co. Water District public water system and groundwater wells are a backup.

Justification:

The station potable and sanitary water system is designed to provide the following: 1) Water for toilets, sinks, showers, and drinking purposes in all permanent personnel areas of the plant site, as required, 2) Water for emergency eyewash and showers, as required, 3) Water to fire protection hoses for various on-site buildings, 4) Water to fill and to provide normal makeup to the Fire Protection Storage Tanks. The change requested by this LDCR is a change of source which is authorized under SFER-4205839. The changes will not have adverse impact to the design bases described in FSAR Section 4.2.5.1.

LDCR-SA-2011-19, EV-CR-2009-001930-5 (GLM) (continued):

Using SCWD as the primary source, the plant potable water distribution piping will function as it currently does.

As discussed in FSAR Section 9.2.4.3, this system is not connected to any radiological systems. Since the system is physically independent of radiological systems, this change to the potable water system has no impact on the plant radiological systems. Should a radiological spill occur, the conclusions of the FSAR for the potable water system are not changed - i.e., the change to the distribution piping is in the same general vicinity as existing potable water distrubition piping and cannot be directly impacted from a radiological spill outside the plant. Therefore the requested change does not adversely affect any FSAR described design function.

Delete the first sentence and revise the second paragraph to reflect that potable water is chlorinated to conform to TDH standards and the emergency shower in the relay house is chlorinated.

Justification:

The station potable and sanitary water system is designed to provide the following: 1) Water for toilets, sinks, showers, and drinking purposes in all permanent personnel areas of the plant site, as required, 2) Water for emergency eyewash and showers, as required, 3) Water to fire protection hoses for various on-site buildings, 4) Water to fill and to provide normal makeup to the Fire Protection Storage Tanks. The change requested by this LDCR is a change of source which is authorized under SFER-4205839. The changes will not have adverse impact to the design bases described in FSAR Section 4.2.5.1. Using SCWD as the primary source, the plant potable water distribution piping will function as it currently does.

As discussed in FSAR Section 9.2.4.3, this system is not connected to any radiological systems. Since the system is physically independent of radiological systems, this change to the potable water system has no impact on the plant radiological systems. Should a radiological spill occur, the conclusions of the FSAR for the potable water system are not changed - i.e., the change to the distribution piping is in the same general vicinity as existing potable water distrubition piping and cannot be directly impacted from a radiological spill outside the plant. Therefore the requested change does not adversely affect any FSAR described design function.

LDCR-SA-2012-2, EV-CR-2012-000111-3 (TJEW):

Justification:

Components FT-142, FT-143, FT-144, and FT-145 are identified within DBD-EE-004 and FSAR Table 7.5-7B (Sheet 3 of 11) as being required to be seismically qualified. The devices are in fact only required to be seismically mounted. DBD-EE-004 section 4.3.2.1.1 states 'Category 2 instrumentation supplied from Non-1E power need not be

LDCR-SA-2012-2, EV-CR-2012-000111-3 (TJEW)(continued):

seismically qualified unless it is part of a seismic Category I system and its failure may degrade this system.' The flow transmitters are N1E, Process Instruments(Isolable,

Offline). DBD-ME-028, attachment 19, identifies that these types of transmitters are ANSI class: N/A, IEEE Class: N1E, Seismic Category: None, Safety Related: No, and EQ: No.

DBD-ME-028, Attachment 19, Table 1, note 3, is associated with components identified as N1E, Process Instruments(Isolable, Offline). This note states that Seismic Category II mounting applies to the non-1E transmitter or gauge. This mounting requirement is identified within Maximo-MEL. The Location-Qualification screen denotes a Component Function Code 2 ('CFC2') attribute of ‘SMTQ’ for FT-142, FT-143, FT-144, and FT-145. From Table 6 of DBD-ME-028, Attachment 19, the SMTQ designation identifies that the components require "Seismic Integrity Evaluation and Mounting of Non-safety Related Instruments Connected to ANSI 2 or 3 Fluid Systems."

Delete "Note 5" for the Variable RCP Seal Water Injection Flow on Sheet 3 of 11 in Table 7.5-7B

LDCR-SA-2012-28, EV-CR-2012-003858-2 (JDS):

FSAR section 15.5.1.2 states under section 4 of the assumptions that "The pressurizer heaters are assumed to be de-energized (the pressurizer heaters at CPNPP are automatically de-energized upon receipt of a safety injection signal by safety-related SSPS relays)." In section 15.5.1.3 of the FSAR, turning off the pressurizer heaters is incorrectly included in the discussion with SI for actions that must occur within 14 minutes of receiving an inadvertent safety injection. Corrected discussion for consistency.

LDCR-SA-2012-23, EV-CR-2012-009618-2 (CBC):

The discussion for RG 1.108 is updated to indicate the frequency for the integrated test sequence / loss of offsite power testing is revised from "At least once every 18 months" to "At the frequency specified in accordance with Technical Specification 5.5.21, 'Surveillance Frequency Control Program' ".. As documented in EV-CR-2011-002186-21, this change was evaluated and approved in accordance with TS 5.5.21.

LDCR-SA-2010-12, EV-CR-2008-003933-5 (GLM):

In the first paragraph, change direct driven open compressors to hermetically sealed type compressors.

Justification:

Plant ventilation chilled water system, subsystem 2, chiller compressors are no longer hermetically sealed type and are now direct driven open compressors. Changing from a hermetically sealed compressor to a direct drive compressor has no impact on the function of the chillers or the plant ventilation chilled water system.

FSAR Amendment 105

LDCR-SA-2012-22, EV-CR-2010-006088-3 (JCH):

Section 3.6B.2.1.1 Reactor Coolant System (RCS) Main Loop Piping

Description: Add the following to the end of Section 3.6B.2.1.1-

"The new Leak Before Break (LBB) leak rate calculation methodology for Alloy 82/182 welds with Structural Weld Overlay (SWOL), has been approved by the Nuclear Regulatory Commission for use in Pressurizer Surge Line (PSL) LBB analysis at another nuclear power plant. This methodology is applicable for CPNPP and has been utilized for the LBB analysis for Alloy 82/182 welds with SWOL for the pressurize surge line nozzle."

Justification:

The revised LBB analysis was performed by Westinghouse and is applicable to both CPNPP U1 & U2 Pressurizer surge lines with SWOL of Alloy 52/52M. The analysis was applied at the Alloy 82/182 Weld locations. The design margin of ten on leak rate, two on flaw size and margin of one on loads remain sufficient to account for changes due to SWOL. Further, the LBBvalidation is not a safety concern since weld overlay has been applied to mitigate the Alloy 82/182 PWSCC issue. Alloy 52/52M is resistant to PWSCC. The revised analysis demonstrated that the required LBB margins are met with no adverse impact on SSCs design function as provided in the referenced UFSAR sections.

The use of LBB analysis was previously approved by the Commission. The current LBB analysis evaluates the piping with the addition of a SWOL on the DMW in order to mitigate PWSCC. The current LBB analysis uses a conservative crack morphology factor that accounts for the PWSCC on Alloy 82/182 weld. The conclusions are that all the recommended margins are satisfied. It is concluded that the previous LBB analyses conclusions remain valid and pressurizer surge line breaks should not be considered in the structural design basis of the Comanche Peak Units 1 and 2 after the SWOL application at the Alloy 82/182 weld locations.

The NRC has approved the current methodology for the Waterford Plant as documented in their safety evaluation. This NRC approved methodology may be utilized by other Licensees so it is not considered a departure from a method of evaluation under 10 CFR 50.59.

The use of the revised LBB analysis with SWOL does not constitute a departure from a method of evaluation described in the UFSAR used in establishing the design basis. Therefore NRC approval and license amendment are not required.

LDCR-SA-2012-6, EV-CR-2012-000748-2 (JDS):

Correct the characterization of the HI-TRAC to show that it is a critical load along with other new heavy loads hoisted over spent fuel in the HI-TRAC/MPC and an MPC. Other paragraph formatting and clarifications were made to reflect the use of the Holtec Dry Cask Storage. The corrected, updated and reformatted FSAR description of critical loads

LDCR-SA-2012-6, EV-CR-2012-000748-2 (JDS) (continued):

moved by the Fuel Building Overhead Crane does not change the description of the crane or its functions to control heavy loads. The correction to the description of the HI-

TRAC as being a critical load is in accordance with the CPNPP heavy loads program and NUREG-0554.

LDCR-SA-2012-16, EV-CR-2011-004569-3 (SCD):

Further detail can be found in the Engineering Basis of FDA-2011-0000133-11 and -12.

Title 10, Part 73, “Physical Protection of Plants and Materials,” Section 73.54, “Protection of Digital Computer and Communication Systems and Networks,” requires licensees provide high assurance that digital computer and communication systems and networks are adequately protected against cyber attacks, up to and including the design basis threat as described in 10 CFR Part 73, Section 73.1.

LDCR-SA-2012-26, EV-CR-2011-012069-5 (TJEW):

FSAR Table 3.9B-10 is being updated to add the active function of “Containment Penetration Protection” for FW check valves FW-0195 through FW-0202. FW check valves FW-0199 through FW-0202 are being revised to indicate that valves 1-FW-0199 through 1-FW-0202 have a Normal Position of "Closed," while valves 2-FW-0199 through 2-FW-0202 still have the Normal Position of "Open." FSAR Table 3.9B-10 is being updated and does not adversely affect or alter the design or functional requirements of the check valves.

On Table 3.9B-10, Sheet 5 of 22,

a.) for valves FW-0195, FW-0196, FW-0197, and FW-0198, add the following words in the last column after the words, "AFW Flow Path"

", Containment Penetration Protection"

b.) add the following four valves after valve FW-0198:

1-FW-0199 FW Check 6 2 Self-Acutated Closed AFW Flow Path, Containment Penetration Protection

1-FW-0200 FW Check 6 2 Self-Acutated Closed AFW Flow Path, Containment Penetration Protection

1-FW-0201 FW Check 6 2 Self-Acutated Closed AFW Flow Path, Containment Penetration Protection

1-FW-0202 FW Check 6 2 Self-Acutated Closed AFW Flow Path, Containment Penetration Protection

LDCR-SA-2012-26, EV-CR-2011-012069-5 (TJEW) (continued):

c.) Also on the same table and sheet, add "2-" to the for the followng valves:

FW-0199

FW-0200

FW-0201

FW-0202

and add the following words in the last column after the words, "AFW Flow Path"

", Containment Penetration Protection"

d.) for valves FW-0195, FW-0196, FW-0197, and FW-0198, add the following words in the last column after the words, "AFW Flow Path"

", Containment Penetration Protection"

LDCR-SA-2012-4, EV-CR-2012-000575-2 (TJEW):

Justification: Liquid mercury is known to promote liquid metal embrittlement (LME) of steels, resulting in premature intergranular cracking. There is the potential for lamp breakage to occur and mercury being released into the pools. Therefore, an evaluation by Westinghouse has been completed to provide a technical analysis of the possible effects of mercury on the integrity of the fuel, stainless steel liner plates, storage racks, and the RCS. After reviewing several possible lamp breakage scenarios and materials compatibility information and using the most limiting scenario, it was determined that the small amount of mercury contamination expected due to lamp breakage will have no significant impact on material integrity in the specified locations. The SPF filters provide removal of fission products and other contaminates by means of filtration and ion exchange. Therefore, any dissolved mercury will be removed via the purification loops.

On page 9.5-79 add the following words in the new section 9.5.3.3:

9.5.3.3 Underwater Lighting

High Pressure Sodium underwater lights are used in the spent fuel pools, transfer canals and wet cask loading pit in the Fuel Building. These lights are subject to inspections and precautions and limitations to control the free mercury contained in the bulbs. These controls minimize the likelihood of the loss of the mercury and requires an evaluation if mercury is lost and not subsequently recovered.

In Table 17A-1, sheet 41 of 58, add the following line at the end of section 37.:

LDCR-SA-2012-4, EV-CR-2012-000575-2 (TJEW) (continued):

"Spent Fuel Pool and Transfer Canal Underwater lights N/A Mfrs Stds - NONE Note C 9.5.3 Note 72, 90 "

In Table 17A-1, sheet 58 of 58, on Note 90:

Delete the word "Portable" and capitalize the "U" in "underwater"

LDCR-SA-2012-8, EV-CR-2007-002309-00-52 (JDS):

Correct descriptions of instruments located in the turbine building (i.e., non-safety related areas) and the feedwater control and bypass valve appurtenances (located in non safety related area mounted on non-safety related valves) Required corrections as noted to be consistent with other FSAR Sections (7.2.1.1.2, 8.3.1.4, and TS Bases 3.7.3). The correction that the instruments located in the turbine building and the feedwater control valve appurtenances are non-safety related is required to be consistent with FSAR Tables 17A-1 and 17A-2 which correctly show that Class 1E, seismic None items are not Nuclear Safety Related. NNS FCVs are backup to the Safety Class 2 FIVs.

These are administrative changes to correct errors made in the FSAR. The changes make these sections consistent with the other FSAR sections.

Corrected Main Feedwater Control and Bypass Valve Status. Seismic Qualification is not applicable. The correction is required to be consistent with FSAR Tables 17A-1 and 17A-2 which correctly show Class 1E, seismic None.

Deleted "safety related" with respect to the turbine trip pressure switches. Section 10.4.7 requires corrections as noted to be consistent with other FSAR Section 8.3.1.4. The correction that the instruments located in the turbine building are non-safety related is required to be consistent with FSAR Tables 17A-1 and 17A-2 which correctly show that Class 1E, seismic None items are not Nuclear Safety Related.

The change makes this section consistent with the other FSAR section.

Changes to correctly show NNS FCVs to be backup to the Safety Class 2 FIVs. Required correction as noted to be consistent with TS Bases 3.7.3.

The changes make this section consistent with the TS Bases.

Separated the Seismic None 1E devices from the Seismic 1E devices to make the application of Note 77 clearer.

LDCR-SA-2012-19, EV-CR-2012-006572-2 (TJEW):

FSAR Table 3A.3-2 references Table 3-1. References to Table 3-1 should read 3A.3-1. This is an administrative issue only and should be corrected in FSAR amendment.

LDCR-SA-2012-19, EV-CR-2012-006572-2 (TJEW) (continued):

On sheet 1 of Table 3A.3-2, change all references to Table 3-1 to Table 3A.3-1.

On sheet 2 of Table 3A.3-2, change all references to Table 3-1 to Table 3A.3-1.

On sheet 3 of Table 3A.3-2, change all references to Table 3-1 to Table 3A.3-1.

On sheet 5 of Table 3A.3-2, change all references to Table 3-1 to Table 3A.3-1.

On sheet 6 of Table 3A.3-2, change all references to Table 3-1 to Table 3A.3-1.

On sheet 7 of Table 3A.3-2, change all references to Table 3-1 to Table 3A.3-1.

On sheet 8 of Table 3A.3-2, change all references to Table 3-1 to Table 3A.3-1.

On sheet 9 of Table 3A.3-2, change all references to Table 3-1 to Table 3A.3-1.

On sheet 10 of Table 3A.3-2, change all references to Table 3-1 to Table 3A.3-1.

On sheet 11 of Table 3A.3-2, change all references to Table 3-1 to Table 3A.3-1.

On sheet 13 of Table 3A.3-2, change all references to Table 3-1 to Table 3A.3-1.

On sheet 14 of Table 3A.3-2, change all references to Table 3-1 to Table 3A.3-1.

On sheet 18 of Table 3A.3-2, change all references to Table 3-1 to Table 3A.3-1.

On sheet 19 of Table 3A.3-2, change all references to Table 3-1 to Table 3A.3-1.

On sheet 23 of Table 3A.3-2, change all references to Table 3-1 to Table 3A.3-1.

On sheet 30 of Table 3A.3-2, change all references to Table 3-1 to Table 3A.3-1.

On page 5.3-12, last sentence of the first paragraph in section 5.3.1.6.2.1, change "Table 3-1" to "The Table below".

On page 6.2-59, last paragraph of sections 6.2.5.1.4, delete ", Table 3-1".

On page 8.3-47, second paragraph of section 8.3.1.2.4, delete the words "Table 3-1 of"

LDCR-SA-2012-24, EV-CR-2011-013842-8 (JDS):

Section 15.6.5.2.6 is revised to remove the calculated values for Peak Clad Temperature, Local Maximum Oxidation, and Core-Wide Oxidation because the values are reported in Tables 15.6-8, 15.6-9, 15.6-10, and 15.6-11. This change removes redundant information from the FSAR.

LDCR-SA-2012-24, EV-CR-2011-013842-8 (JDS) (continued):

Table is revised to include results for assessment of the thermal conductivity degradation (TCD) issue identified in NRC Information Notice 2011-21 while crediting peaking factor burndown.

LDCR-SA-2013-2, EV-CR-2011-012069-12 (TJEW):

On Table 3.9B-10, Sheet 5 of 22, for valves, FW-0195 to FW-0198, 1-FW-0199 to 1-FW-0202, and 2-FW-0199 to 2-FW-0202,

1.) replace the words under the column "Normal Position" with the words "Open/Closed" and

2.) replace the words under the column "Function (Note 5)" with "See Note 9, below"

On Table 3.9B-10, Sheet 22 of 22, add Note 9 that says,

"9) The feedwater check valves in the auxiliary feedwater lines to the steam generator open to provide the AFW flowpath during design basis events. These valves must close in the event of a line break upstream of the outboard check valve in order to terminate a Condition III loss of feedwater event. In addition, these valves also must close post-LOCA to protect the cold containment penetration during intermittent operation of AFW."

LDCR-SA-2012-18, EV-CR-2011-008432-7 (JDS):

Figures 6.2.1-1 and 6.2.1-2 are removed and the List of Figures for Section 6.0 is updated to reflect their deletion as a result of the impact of NSAL 11-5 "Westinghouse LOCA Mass and Energy Release Calculation Issues" and correct the Time for Peak Temperature for DEPSG - MAXSI.

Figure 6.2.1-1 removed as a result of the impact of NSAL 11-5 "Westinghouse LOCA Mass and Energy Release Calculation Issues" and correct the Time for Peak Temperature for DEPSG - MAXSI.

Figure 6.2.1-2 removed as a result of the impact of NSAL 11-5 "Westinghouse LOCA Mass and Energy Release Calculation Issues" and correct the Time for Peak Temperature for DEPSG - MAXSI.

Section 6.2.1.1.3.2, the reference to WPT-17251 with regards to EQ qualification and the containment pressure and temperature analysis for LOCA is removed since the EQ qualification was revised based to reflect the impact of NSAL 11-5 in RXE-LCA-CPX/0-106.

The values listed in FSAR Table 6.2.1-2 were taken from WPT-17127 "Revised LOCA Containment Response Data", Table 2. The Time for Peak Temperature for the DEPS-MAXSI was incorrectly transcribed into the FSAR from the time for peak sump

FSAR Amendment 105

LDCR-SA-2012-18, EV-CR-2011-008432-7 (JDS) (continued):

temperature (1722.0 sec) instead of the time for peak steam temperature (24.0 sec). These values are corrected on Table 6.2.1-2.

LDCR-SA-2012-27, EV-CR-2012-010400-1 (SCD):

Administrative change from OSL (Optically Stimulated Luminescence) to TLD (Thermoluminescent Dosimeter) use at CPNPP.

LDCR-SA-2012-21, EV-CR-2012-008468-1 (SCD):

Update of titles and resumes of CPNPP Key personnel occuring since last FSAR Amendment

LDCR-SA-2012-20, EV-CR-2010-000880-7 (SCD):

Corrective actions for CR-2010-000880. ANSI-N45.2.9-1974 does not discuss electronic records, therefore the statement about duplicate storage of electronic records per the ANSI is incorrect and is being removed.

LDCR-SA-2013-3, EV-CR-2012-009307-2 (SCD):

The ability to pulse the air scrub was identified by the vendor after the system was installed. The omission of the pulsation device was overlooked and not included in the original design. Without a pulsation device the air scrub would be ineffective and this would result in permanent fouling of the Reverse Osmosis membranes.

FSAR Amendment 105a

LDCR-SA-2013-5, EV-CR-2009-005301-00-29 (TJEW):

Revise Figure 8.2-4 to show breaker E11 (CB 8075) and its air switches.

Revise Figure 8.2-5 Sheet 1 of 2 to show breaker E11 (CB 8075) and its air switches.

LDCR-SA-2013-1, EV-CR-2012-000272-18 (JDS):

The change clarifies that the top and bottom 6 inches of each fuel rod, or blanket region, typically contain fuel of lower enrichment (2.6 w/o U-235) than found in the remaining fuel rod length (central zone). This clarification is necessary because not all fuel rods have a blanket region with different enrichment. For example, the Unit 2 Cycle 14 core contains 4 fuel assemblies with blanket enrichments equivalent to the central zone enrichment of 2.308 w/o U-235.

LDCR-SA-2013-8, EV-CR-2013-001939-1 (JDS):

Updated FSAR Table 6.3-11, RWST Outflow for a Large Break LOCA with a Worst Single Failure, with the correct "Cumulative Change in RWST Volume" and correct the typo "12,46" to "12,464" Previously approved in LDCR SA-2006-010 (EVAL-2005-003364-03) but failed to be incorporated into the FSAR update. Typo is a clarifiction of volume of the RWST (12,464 gallons) or 6% indicated level of 13,450 gallons as discussed in note 11 of Table 6.3.11.

LDCR-SA-2012-12, EV-CR-2012-003165-2 (JCH):

Description: Add the following valves to Table 3.9B-10, "Active Valves"

Valve ID: DO-0111/DO-0187/DO-0211/DO-0287

System: DO

Valve Type: RELIEF

Size In.: 1-1/2

ANS Safety Class: 3

Method of Actuation: SELF-ACTUATED

Normal Position: CLOSED

Function: Pressure Relief

LDCR-SA-2012-12, EV-CR-2012-003165-2 (JCH) (continued):

Justification: These valves are required to protect diesel fuel oil transfer pumps when backpressure from the "Y" strainers requires it. Since this could happen during the Emergency Diesel Generator mission time (30 Days) and no credit had been taken for online maintenance or operator action to protect the pumps, these valves must be classifed as ACTIVE to perform their function as described in the FSAR.

LDCR-SA-2012-5, EV-CR-2012-000036-1 (JCH):

Description: The following changes to FSAR Section 10 are required to document these system changes.

1. Section 10.4.3.1.2 - Feedwater Pump Turbine Seals

Delete "The feed pump turbine seal steam system also incorporates a steam seal dump valve to establish the required flow of seal steam through the seal steam supply header."

2. 10.4.3.2.1.a Normal Operation Conditions

Delete "Excess steam pressure is dumped to the condenser through the steam seal dump valve."

3. 10.4.3.2.2.b Feedwater Pump Turbine Steam Seal System

Revise Para. 1 and 2, "In the event of excessive packing wear or blowout, the packing leakage increases drastically; this causes the steam seal supply valve to modulate close and the steam seal dump valve to open enough to maintain sealing pressure of four psig. As the SSSV controller senses a rising gland steam pressure, its pneumatic output increases to throttle close the supply valve. If the wide open steam seal dump steam seal supply valve cannot maintain pressure at four psig, the pressure increases until the relief valve starts opening at about 20 psig. At 25-psig seal header pressure, the relief valve is wide open together with the steam seal dump valve, and further increase in flow increases header pressure beyond 25 psig.

Loss of air supply to the controller causes the steam seal supply valve and the steam seal dump valve to open wide, and any pressure increase beyond 20 psig again opens the relief valve."

4. 10.4.3.5.2 Feedwater Pump Turbine Steam Seals

Revise Para. 1, "Gland steam header pressure is maintained at a three psig set point by modulation of the steam seal supply valve and the steam seal dump valve. A split range controller sets the air pressure at each the control valve so that sufficient steam is admitted from the auxiliary Steam System (if needed) and excess steam is dumped to the condenser."

LDCR-SA-2012-5, EV-CR-2012-000036-1 (JCH) (continued):

Justification:

As a result of these changes, the FWP Turbine Gland Steam System will operate with a single supply valve (u-PV-3918A) that modulates as needed to provide sealing steam and maintain header pressure at approximately 3 psig. A loss of air supply, loss of controller input or loss of controller output will cause the supply valve to fail open to provide the maximum sealing steam pressure. With the wide open supply valve, the pressure will increase until the system relief valve (uGS-0110) starts opening at about 20 psig. At 25 psig seal header pressure, the relief valve is wide open. The relief valve is sized to handle the full steam flow and pressure from a wide open supply valve. There is no dump valve to in this configuration.

LDCR-SA-2012-1, EV-CR-2010-004331-62 (JCH):

Description: Add the following to Table 9.3-9, "Failure Mode and Effects Analysis Chemical and Volume Control System Active Components - Normal Plant Operation and Load Follow" on sheet 34 of 35:

Component: 55. Motor operated gate valve 8402A

Failure Mode: Fails closed.

CVCS Operation Function: Charging and Volume Control - charging flow.

Effect on System Operation and Shutdown: Failure inhibits use of normal charging line to RCS for boration, dilution, and coolant makeup operations. Seal water injected path remains available for boration of RCS to a hot standby concentration level and makeup of coolant during operations to bring the reactor to hot standby condition.

Failure Detection Mode: Valve position indication (closed to open position chang) and group monitoring light (valve closed) at CB.

Justification:Justification:

This modification will resolve OMA Group 1 "Normal Charging Isolation" with regards to manual operator actions of motor operated valves 1(2)-8105 and 1(2)-8106. The new 3-inch motor operated valve is classified as Nuclear Safety Class 2. The control switch will be used to isolate and bypass 1(2)-HCV-0182 during maintenance and in case of a fire to ensure that the normal charging path is isolated. Replacement of this manual operated valve with a motor operated gate valve will maintain all design and operational functions of the existing valve. Addition of valve 1(2)-8402A will have similar failure modes and actions to those listed for isolation valves 1(2)-8105 and 1(2)-8106. Therefore, there is a minimal increase in the likelihood of occurrence in a malfunction.

The requirement that the valve is a "PASSIVE" open valve.

FSAR Amendment 105a

LDCR-SA-2012-1, EV-CR-2010-004331-62 (JCH) (continued):

Description: Add the following to Page 5A-10 after Normal Charging Isolatin Valves 8105 and 8106-

"Alternate Charging Isolation Valve 8402- If this normally open motor-oprerated valve closes spuriously, operator action can be used to denergized the valve operator and reopen the valve with its handwheel.

Justification:Justification:

This modification will resolve OMA Group 1 "Normal Charging Isolation" with regards to manual operator actions of motor operated valves 1(2)-8105 and 1(2)-8106. The new 3-inch motor operated valve is classified as Nuclear Safety Class 2. The control switch will be used to isolate and bypass 1(2)-HCV-0182 during maintenance and in case of a fire to ensure that the normal charging path is isolated. Replacement of this manual operated valve with a motor operated gate valve will maintain all design and operational functions of the existing valve. Addition of valve 1(2)-8402A will have similar failure modes and actions to those listed for isolation valves 1(2)-8105 and 1(2)-8106. Therefore, there is a minimal increase in the likelihood of occurrence in a malfunction.

the requirement that the valve is a "PASSIVE" open valve.

FSAR Amendment 105b

LDCR-SA-2013-15, EV-CR-2013-007598-1 (GLM):

In the 5th paragraph, clarify the description of the location of instrumentation in section 9.2.2.3.

For #7 "Thermal Barrier Cooler", clarify the description of the location of instrumentation in section 9.2.2.5.3.

Technical Justification: Correction is required by CR-2013-007598. The flow diagram (FSAR Figure 9.2-3) shows the instrumentation (temperature and flow) downstream of each thermal barrier. The ICDs attached to the CR show the redundant and diverse design. The importance of redundancy and diversity in the instrumentation and the valves should be clarified because the Thermal Barrier Rupture event is an intersystem LOCA and could challenge the CCW system outside containment. See SSER 17 for additional information.

LDCR-SA-2013-10, EV-CR-2012-012849-3 (JCH):

Section 10.2.2.7.5 Turbine Stop and Control Valves

Description: Page 10.2-12

Correct information on the closure time of the extraction steam non-return check valves from "two (2) seconds" to "one (1) second".

Justification:

The non return check valves of the extraction steam system are credited for prevention of turbine overspeed with a one second closure requirement to isolate the turbine from the moisture separator reheaters (Ref: DBD-ME-205, Rev 12, Section 4.3.1.2). The one second closure time was also specified in specification 2323-MS-021D.2,which the valve was purchased under. Changing FSAR Section 10.2.2.7.5 to identify the correct closure timerequirement will bring it into alignment with the remainder of the FSAR descriptions of the extraction steam check valves, the DBD, and the valve specification.

LDCR-SA-2013-9, EV-CR-2013-003868-1 (JDS):

FSAR 9.3.4.1.2.3, Reactor Makeup Control System, does not explicitly address the increases in RCS boron caused by burnable poison depletion during the first months of operation. Other sections of the FSAR (e.g. 4.2.2.3, 4.3.2.1, and 4.3.2.4.11) address increased in chemical shim (boron acid concentration) in the primary coolant to offset reactivity effects of burnable poison depletion.

Include description of burnable poison depletion for consistency with chapter 4 of the FSAR.

FSAR Amendment 105b

LDCR-SA-2013-20, EV-CR-2013-003797-2 (JDS):

Update FSAR 15.4.7.2 to clarify the wording related to core loading verification in a manner consistent with the referenced analysis, WCAP-16676-NP, Ref. 1 to FSAR Section 15.4.7. Clarification needed to ensure the FSAR text is consistent with the CPNPP practice and as outlined in WCAP-16676-NP.

LDCR-SA-2013-22, EV-CR-2013-008406-1 (RAS):

Revise the 2nd sentence in the last full paragraph:

"Power relief valves limit system pressure for large positive pressure transients. In the event of a large load reduction, not exceeding the design plant load rejection capability, the pressurizer power operated relief valves might be actuated for the most adverse conditions, e.g., the most negative Doppler coefficient, and the maximum incremental rod worth."

by replacing the phrase "...the most negative Doppler coefficient, and the maximum incremental rod worth." with "…Beginning of Life conditions."

Westinghouse has advised that the Analysis of Record for a large load rejection not exceeding the plant design capability for the most adverse conditions was for beginning of life, not for most negative Doppler coefficient and maximum incremental rod worth.

LDCR-SA-2013-23, EV-CR-2013-003664-1 (RAS):

Corrects an editorial error by revising a label from "HI-4" to HI-1". There is no "HI-4" signal and the indicated signal path is correctly referred to as "HI-1" in plant design documents.

LDCR-SA-2013-12, EV-CR-2013-005620-1 (TJEW):

On page 8B-2,

1.) in the third paragraph, change the word "modificaitons" to "modifications" and

2.) in the forth paragraph, remove the sentence, "In the defuelled mode, TS do not apply."

LDCR-SA-2013-19, EV-CR-2013-010298-1 (RAS):

Revise the last paragraph in section 3.6B.2.1.1 to specify use of Waterford LBB methodology for Alloy 82/182 welds with structural weld overlay.

FSAR Amendment 105b

LDCR-SA-2013-24, EV-CR-2013-008362-6 (SCD):

Transitioning Nuclear Oversight (NOS) to be a direct reporting relationship to the Vice President Station Support is based on industry experience and supports the INPO Performance Objectives and Criteria for organizational effectiveness. This organizational structure is consistent with industry practices and helps ensure that Nuclear Oversight independence remains strong. This organizational change will ensure that NOS maintains a strong reporting relationship up to the CNO and other external organizations. The responsibilities of the Director, Oversight and Regulatory Affairs have been re-assigned to the Manager, Nuclear Oversight. The personnel qualifications section, 17.2.1.5.1, has been changed to correspond with Table 13.1-1.

Correct an error that was introduced to the TMI section during incorporation of LDCR-SA 2007-001. Wording was changed to specify that the Performance Improvement Department is assigned the functions of the former ISEG organization.

This organizational change will ensure that NOS maintains a strong reporting relationship up to the CNO and other external organizations. The responsibilities of the Director, Oversight and Regulatory Affairs have been re-assigned to the Manager, Nuclear Oversight.

The responsibilities of the Director, Oversight and Regulatory Affairs have been re-assigned to the Manager, Nuclear Oversight. The personnel qualifications section, 17.2.1.5.1, has been changed to correspond with Table 13.1-1.

The responsibilities of the Director, Oversight and Regulatory Affairs have been re-assigned to the Manager, Nuclear Oversight.

LDCR-SA-2013-4, EV-CR-2012-006134-46 (GLM):

Update Section 3.5.1.4 to include the identification and description of the tornado missile impact analysis results on the Auxiliary Feedwater Pump Turbine Exhaust Stack that is not contained within reinforced concrete building or structures.

Add missing details to the FSAR for identification for this safety-related system/ components subjected to tornado-generated missiles. This also resolves the NRC question and identified NCV issue documented in the NRC Inspection Report dated 07/ 24/2012. Calculation CS-CA-0000-5493 was generated to support the impact analysis, while attempts to locate historical design information supporting the asbuilt configuration could not be located or recovered.

FSAR Amendment 105b

LDCR-SA-2013-17, EV-CR-2013-009990-1 (JDS):

The peak overpower is stated to be 118% which is inconsistent with Tables 4.1-1 and 15.0-4, which lists overpower to be 118.5%. The correct overpower was verified to be 118.5% for both units by Westinghouse LTR-TA-13-8 and LTR-TA-12-124. The overpower value has been updated to 118.5% for consistency between sections of the FSAR and with the assumptions made in the design basis analysis.

Figures 6.2.1-3 and 6.2.1-4 are both related to containment pressure temperature analysis for MSLB and do not include LOCA information. This wording which implies that these graphs contain LOCA related data was to be updated in a previous FSAR change. Reference to LOCA with regards to Figures 6.2.1-3 and 6.2.1-4 has been removed as originally required by a previous change to the FSAR (LDCR 2012-018).

A previous change to the FSAR (LDCR 2012-008) also updated the information concerning the containment analysis that supports environmental qualification evaluations in Section 6.2.1.1.3.2. This update included the phrase "modified GOTHIC run" which is misleading since no change to the actual GOTHIC code was implemented. The "modified" refers to different design inputs to GOTHIC that were used to support EQ analysis. This paragraph already describes the difference in design inputs and so "modified" has been stricken for clarity.

LDCR-SA-2013-21, EV-CR-2013-001520-1 (GLM):

In the 2nd paragraph change "...normal supply is unavailable." to "...Condensate Storage Tank is depleted."

Justification

Clarify SSW/AFW Interface to show that SSW is the long term back-up to the CST. It is used after the Tech Spec usable volume of the CST is depleted.

The Technical Specification BASES for the ST also cites the back up function. SER Sections 9.2.5, 9.2.6, and 10.4.9 are consistent with the FSAR; but are more clear that failure of the CST is not postulated. SER 9.2.5 is the most specific and makes it clear the SSI water is in addition to the CST, not in lieu of the CST.

"Additional water is also available from the service water system."

Calculation ME(B)-088 determined the flow based flow on demand after depletion of the CST rather than on full flow in lieu of the RWST. This is consistent with the design of the SSW backup function.

In the 6th paragraph update the SSI volume that would be used if the CST was unavailable in a beyond the design basis event for the current licensed thermal power of 3612 MWT

LDCR-SA-2013-21, EV-CR-2013-001520-1 (GLM) (continued):

Justification

The change administratively updates the SSI volume that would be used if the CST was unavailable in a beyond the design basis event to be consistent with the current licensed thermal power of 3612 MWT [(3612 MWT X 60 gal/MWT)/325,900 gal/acre-ft = 0.665 acre-ft].

FSAR Amendment 106

LDCR-SA-2013-7, EV-CR-2012-011569-2 (GLM):

The description of the source of potable water to the site and references to the Potable Water Storage Tank and well pumps given in FSAR Sections 9.2.4.2, 9.2.4.3, and 9.2.4.4 are changed to reflect that the site receives water solely from the Somervell County Water District and no longer uses the Potable Water Storage Tank or well pumps. The change to the source of site water is facilitated by the modifications described in FDA-2013-000044-1 and in SFER-4606965.

The modifications described in FDA-2013-000044-1 and in SFER-4606965 facilitate a change to the source of potable water to the site. As shown in 10CFR50.59 Screening 59SC-2013-000044, none of the modifications adversely affect the design bases of the Potable and Sanitary Water System described in FSAR Section 9.2.4.1. SFER-4208539 determined that the Somervell County Water District (SCWD) is capable of being the sole provider of both water pressure and capacity sufficient to fulfill the design basis functions of the Potable and Sanitary Water System. Additionally, the adequate operation of the Potable Water System with SCWD as the preferred water source since the implementation of FDA-2009-001930-01 and SFER-4208539 indicates that the Potable and Sanitary Water System can draw water solely from the Somervell County Water District and continue to fulfill its design basis functions. Therefore, all components associated with the onsite production of water can be disconnected from the rest of the system and abandoned in place.

LDCR-SA-2013-26, EV-CR-2013-001054-8 (GLM):

In the last paragraph, change the last sentence to say ".... safe shutdown of the other unit, or simultaneous shutdown of both units and maintaining them both in a safe shutdown condition."

In the 4th paragraph, change 93 acre-feet to 94 acre-feet and change 3.8 ft to 3.9 ft. In the 5th paragraph, update the max water consumption at 30 days and 39 days to 78.4 acre-feet (766'-4") and 99.4 acre-feet (765'-4"), respectively.

In the 2nd paragraph, change 765 ft 8 in to 766 ft 4 in. at 30 days and 765 ft. 4 in. at 39 days.

Technical Justification: The Safe Shutdown Impoundment Hydrothermal Analysis, ME-CA-0000-3264, was updated due to Stretch Power Uprate. It simulated one unit in a two train cooldown due to a Loss Of Coolant Accident (LOCA) and the other unit during a two train cooldown with a Loss Of Offsite Power (LOOP) as required by RG 1.27. The starting elevation is 769 feet 6 inches which is the invert of the equalization channel between the SSI and Squaw Creek Reservoir. The result for a LOCA is summarized in Table 14 of ME-CA-0000-3264 Revision 3, which shows that the maximum SSI loss due to evaporation of 93.7 ac-ft and a minimum surface water elevation after 39 days is 765 feet 7 inches. The difference between 769 feet 6 inches and 765 feet 7 inches is approximately 3.9 feet. The result for a two train cooldown with a LOOP is summarized in Table 16 of ME-CA-0000-3264 Revision 3, which shows the maximum SSI loss due to evaporation of 78.4 ac-ft at 30 days and 99.4 ac-ft at 39 days, corresponding to water

LDCR-SA-2013-26, EV-CR-2013-001054-8 (GLM) (continued):

surface elevations of 766 ft 4 in and 765 ft 4 in, respectively. Therefore, FSAR Section 2.4.11.5 need to be updated to account for both the effects of an accident in one unit, to permit the safe shutdown of the other unit, or simultaneous shutdown of both units and maintaining them both in a safe shutdown condition. FSAR Section 2.4.11.5 will also be updated to state that the minimum water elevation is 766 ft. 4. At 30 days and 765 ft. 4 in. at 39 days. FSAR Section 9.2.5.3.3 needs to be updated to state that the maximum consumption is approximately 94 ac-ft, and the decrease in surface water elevation is 3.9

LDCR-SA-2014-1, EV-CR-2013-008265-5 (JDS):

Update tables to reflect PCT errors due to ECCS model changes in Best Estimate LOCA for Unit 1 and Unit 2

LDCR-SA-2014-2, EV-CR-2012-011620-14 (SCD):

The nozzle check valve is a ASME Section III Class 1513 valve with a pressure rating of 3632 psig at 100F and a design rating of 2485 psig at 650F per drawing MD22754 Revision E (VDRT-3902424). This meets the requirements of 2323-MS-43B Category 2501 component. For flow characteristics, Westinghouse reviewed the new valve and the old valve and concluded the flow changes are insiginificant and acceptable; the Westinghouse conclusions regarding 2SI-8819A are documented in WPT-17762. The replacement valve is designed and manufactured in accordance with the requirements of ASME B&PV Code Section III, Class 1, 1974 Edition through winter 1975 Summer Addenda.

LDCR-SA-2014-3, EV-CR-2013-003295-5 (SCD):

Update table 17A-1 to include alternate penetration insert.

LDCR-SA-2014-5, EV-CR-2013-011618-2 (GLM):

In Section 1.2.2.8.2 add comma after the word "functions."

This is an editorial change only. This comma was supposed to be included via LDCR SA-2003-013, but for some reason it was not.

LDCR-SA-2014-7, EV-CR-2013-011896-1 (GLM):

Add drawing M1-0216-01 to the list of drawings for Figure 9.3-1 on page 9-xiii..

Add drawing M1-0216-01 to Figure 9.3-1.

Technical Justification: M1-0216-01 is correctly denoted as included in Figure 9.3-1; however, it is not included in the table of contents or in the FSAR Figure. This indicates the error was more than likely made when the FSAR special figures were reverted to

LDCR-SA-2014-7, EV-CR-2013-011896-1 (GLM) (continued):

plant drawings in the 1990's to reduce such errors. This is an editorial change because it corrects an error in incoporating previously approved changes.

Technical Justification: M1-0216-01 is correctly denoted as included in Figure 9.3-1; however, it is not included in the table of contents or in the FSAR Figure. This indicates the error was more than likely made when the FSAR special figures were reverted to plant drawings in the 1990's to reduce such errors. This is an editorial change because it corrects an error in incoporating previously approved changes.

LDCR-SA-2014-6, EV-CR-2013-010811-1 (SCD):

The gamma detectors provide the radiation monitoring during routine operation at CPNPP while the additional beta/gamma radiation detectors availability are necessary for less frequent and emergency condition which might warrant them.

LDCR-SA-2014-9, EV-CR-2013-008403-6 (SCD):

Incorporated editorial corrections to the last paragraph in section 6.3.5.4.1 by replacing "taking" with "the" in the first sentence and "less" with "loss" in the second sentence.

“The change from 28 ft to 22 ft for required NPSH is based on the vendor. The change in NPSHa from 32 ft (based on a previous empty alarm setpoint) to 26.7 ft is based on the current alarm setpoint (based on the end of injection mode of operation as described in Section 6.3.2.2.10.2). These changes reflect corrections to the NPSH calculations to reflect the current plant design.”

LDCR-SA-2014-11, EV-CR-2013-008397-4 (TJEW):

The following is an NRC finding documented in the NRC Component Design Bases Inspection Report, IR 2013007:

The inspectors identified a Severity level IV, non-cited violation of 10 CFR 50.71(e)(4), requires the UFSAR be updated, at intervals not exceeding 24 months, and states in part, "the revisions must reflect all changes made in the facility or procedures described in the UFSAR." Specifically, prior to June 20, 2013, the inspectors identified the alternate power diesel generator system was not described in sufficient detail in the FSAR as required. This LDCR corrects the problem.

On page 8.3-1, Section 8.3.1.1. subsection 3, add the following words, "CPNPP has also provided a set of Alternate Power Diesel Generators (APDGs) for each unit with the capability to connect to a Class 1E train at a time to provide defense-in-depth for safe shutdown of a unit during outages or during extended duration of an inoperable offsite circuit on occurrence of a beyond design basis event of concurrent loss of offsite power and failure of EDGs. The APDGs may provide 3450 kVA to provide long term cooling of each unit to respond to a beyond design basis event."

FSAR Amendment 106

LDCR-SA-2012-13, EV-CR-2012-005259-3 (TJEW):

Figure 1.2-1 is revised to show the location of XST1A

Page 8.2-1 will add a new paragraph after the 7th paragraph and will state, "Startup transformer XST1 and alternate startup transformer XST1A are connected to a common overhead line from the 138-kV switchyard. Each transformer is provided with a 138-kV motor-operated air switch such that each transformer can be energized independent of the other transformer."

In the last paragraph on the same page, the word "spare" will be replaced with "alternate"

On page 8.2-2, after the first partial paragraph, the following new paragraph will be added, "Alternate startup transformer XST1A is located under the 138-kV line to XST1 (refer to Figure 8.2-1) to serve as a replacement of XST1 after a future plant modification to connect cable buses from secondary X and Y windings of XST1 and XST1A to transfer panels to provide 138-kV offsite power to Units 1 and 2 safety related buses."

In the next paragraph after the new paragraph above, replace the word "Spare" with "Alternate", delete the word "dedicated" and deleted the last sentences that says, "This spare transformer may be physically relocated to a dedicated location near XST1, to serve as a replacement of XST1."

Figure F 8.2-1 is revised to show location of alternate startup transformer XST1A and revise designation of XST2A.

On Figure 8.2-4 show the electrical network interconnection of XST1/ XST1A and revise the detail for XST2/XST2A.

On Figure 8.2-7 Sheet 1, XST1A willl be added to the transmission lines going to XST1 from the 138kV switchyard.

On Figure 8.2-7 Sheet 2, XST1A will be added to the 138kV transmission tower.

Figure 8.2-9 will be updated to show transformer XST1A in the 138kV transformer connections plan and elevations and new air switch configuration for transformers XST1 and XST1A

Figure 8.2-11 will be updated to reflect the as-built cable bus configuration.

New Figure 8.2-11A will show the as built details of the XST1A cable bus configuration to the 6.9kV switchgear.

On page 9.5-17, last sentence of section 9.5.1.5.6, replace the word "spare" with "alternate, and at the end of the paragraph add the following words, "Alternate transformer XST1A is separated from adjacent structures by a three-hour rated fire wall."

LDCR-SA-2014-15, EV-CR-2013-008397-12 (TJEW):

The linkage to beyond design basis event is being deleted as a result of LDCR SA-2014-011 because the FSAR is a design basis document, i.e., a 10CFR50.2 plant, in FSAR section 8.3.1.1.1.

On page 8.3-1, LDCR SA-2014-011 inserted a paragrapgh after section 8.3.1.1.1.3 that said, "CPNPP has also provided a set of Alternate Power Diesel Generators (APDGs) for each unit with the capability to connect to a Class 1E train at a time to provide defense-in-depth for safe shutdown of a unit during outages or during extended duration of an inoperable offsite circuit on occurrence of a beyond design basis event of concurrent loss of offsite power and failure of EDGs. The APDGs may provide 3450 kVA to provide long term cooling of each unit to respond to a beyond design basis event."

This LDCR will modify the above paragraph as follows:

1. In the first sentence, add the words, "non-safety related" before Alternate Power Diesel Generators.

2. In the first sentence delete the words, "a beyond design basis event of."

3. In the second sentence delete the words, "to respond to a beyond design basis event."

4. Add the following sentence to the end of the paragraph, "See Section 8.3.1.2.1.7.h for a discussion of the sizing of APDG cables."

On page 8.3-38,

1. second paragraph and second sentence of section h., relocate the words "during modes 5 and 6" to after the word "APDGs."

2. third paragraph and first sentence of section h, replace the "," between 6,9kV to a "period."

LDCR-SA-2014-14, EV-CR-2013-008362-17 (SCD):

Due to CPNPP organizational and upper management changes, Chapter 17 and the TMI Section of the FSAR is being revised.

LDCR-SA-2014-16, EV-CR-2013-011292-1 (JDS):

Update core thermal power output from 3458 MWt to the currenctly licensed power level of 3612 MWt.

FSAR Amendment 106

LDCR-SA-2014-17, EV-CR-2014-001610-1 (JDS):

Include exception for use of the 193 core offload spaces for storage to assure ability to comply with Cask Technical Specifications. This will assure that 32 spaces will remain available for cask offload.

Clarification. The word "hose" should be "hoist".

LDCR-SA-2014-18, EV-CR-2012-005259-93 (TJEW):

Add Figure 8.2-11A to the List of Figures for Chapter 8 of the FSAR on page 8-iv:

8.2-11A Spare Start-up Transformer XST1A Cable Bus Connection to 6.9 KV Switchgear

LDCR-SA-2014-13, EV-CR-2014-006885-1 (SCD):

Due to CPNPP organizational and upper management changes, Chapter 13 of the FSAR is being revised.

LDCR-SA-2011-4, EV-CR-2010-005675-1 (JDS):

Update UFSAR Section 15.6.2 to provide revised post-SPU EAB and LPZ estimated doses for a CVCS letdown break during a system alignment using 3 letdown orifices at Mode 3 operation where the system is below 500 degrees F. The Thyroid and Whole Body doses limits for the EAB and LPZ are based on a small fraction (10%) of the 10CFR100 as directed by the applicable SRP guidelines. 10CFR100 dose limits for the thyroid and whole body doses are 300 rem and 25 rem, respectively. The resulting dose margins derived remain less than a small fraction of the 10CFR100 limits.

FSAR Amendment 106a

LDCR-SA-2014-20, EV-CR-2013-003649-5 (JCH):

Table 3.9B-10: Active Valves

Description: Correct typo for valve 2DO-0052 (shown as 2DD-0052 on Sheet 15)

Move valves DO-0111, DO-0187, DO-0211 on page 19 and DO-0287 on page 20 to sheet 15 and change the function of these valves from Pressure Relief to Recirculation Flow Path.

Justification: Pressure relief is not the active safety function of the subject valves. These valves provide Recirculation Flow Path (miniflow) for the fuel oil pumps. The subject valves were also inserted in the wrong location in the table.

LDCR-SA-2013-6, EV-CR-2010-009018-22 (JDS):

Clarification by providing a more detailed nominal dmension of the Region 1 spent fuel storage racks in the fuel building.

Update the minimum Boron Concentration for the spent fuel pools to be consistent with License Amendment 162.

Replace Table 9.1-4 with a revised table reflecting the revised spent fuel pool criticality analysis approved in TS amendment 162.

Update criticality codes used to reference SCALE 5.1 and PARAGON to reflect codes used in the spent fuel pool criticality analysis.

Update to include descriptive information for the revised spent fuel pool criticality analysis approved in amendment 162 and revise the references to the WCAP used in the license amendment.

LDCR-SA-2014-21, EV-CR-2014-010150-2 (SCD):

This activity lowers the minimum acceptable filter mesh size of the Reactor Coolant System (RCS) Filter from 0.1 micron to 0.05 micron in DBD-ME-255 to reduce source term dose in the Chemical Volume and Control System (CVCS).

LDCR-SA-2014-26, EV-CR-2013-006623-5 (JDS):

Correct inconsistency between Table 6.2.4-1,Table 6.2.4-2, Figure 6.2.4-1 and Table 6.2.4-3.

Update the function and classification of 1/2-HV-2154 and 1/2-HV-2155 to no longer function as Containment Isolation Valves. The containment isolation function was previously transferred to locked closed manual isolation valves, FW-0113 and FW-0116. FSAR Tables 6.2.4-1 and 6.2.4-2 identify FW-0113 (Item #22) and FW-0116 (Item #20) as the Feedwater Sample line containment isolation valve for penetration MI-5 and MI-6,

LDCR-SA-2014-26, EV-CR-2013-006623-5 (JDS) (continued):

respectively. Table 6.2.4-1 references Figure 6.2.4-1 Arrangement 16 as the containment isolation valve arrangement which depicts a locked closed isolation valve outside of containment. Table 6.2.4-1 also references FSAR Figure 10.4-9 which shows FW-0113/0116 as normally locked closed for containment isolation. Table 6.2.4-2 describes the isolation valves as locally operated manual valves. This is consistent with DBD-ME-203, Rev. 36 Section 4.3.1.2.i and 5.4.1 which identify a locked closed manual valve containment isolation arrangement fulfilled by FW-0113 and FW-0116. However, previous FSAR updates missed the removal of the reference to the properties of the former containment isolation valves in Table 6.2.4-3 and incorrectly describes the valves as having a containment isolation signal, power source, and closure time. The Table also incorrectly shows the normal valve position as open. DBD-ME-013, Attachment 2 (Items 20 and 22) provides the correct properties for FW-0113/0116 that should be reflected in Table 6.2.4-3.

Table 6.2.4-3 is updated to be consistent with DBD-ME-203, DBE-ME-013, FSAR Tables 6.2.4-1 and 6.2.4-2, and FSAR Figure 6.2.4-1.

LDCR-SA-2014-12, EV-CR-2014-005546-1 (SCD):

Spent fuel pool swing gate pressure seals have been re-classified as safety related from not safety related components. Additional information will be added to show the new spent fuel pool swing gate equipment as shown in the following attachments. (Reference FDA-2013-000052-01)

LDCR-SA-2014-22, EV-CR-2014-005228-1 (SCD):

FSAR Tables 3.2-3 and 3.2-4 are updated to reflect the flow diagram split that created drawings M1-0269 Sh. C and D.

The Ch. 11 Listing of Figures is updated to reflect the flow diagram split that created drawings M1-0269 Sh. C and D.

Figure 11.3.-1 is updated to reflect the flow diagram split that created drawings M1-0269 Sh. C and D.

LDCR-SA-2014-19, EV-CR-2013-008947-12 (SCD):

The pressure gauges for the airlocks are special cases due to their Safety Class 2 function as part of the airlocks. Typical pressure gauges on Safety Class piping are classified as NNS because they are isolable and/or minor leakage is acceptable. The subject valves are not accessible and post-LOCA increase in leakage is not acceptable. Therefore, they are being classified as ANSI Safety Class 2, Seismic Category I under FDA-2012-000230-02.

FSAR Amendment 106a

LDCR-SA-2014-25, EV-CR-2014-002884-11 (JDS):

Revise Note (a) to Table 15.0-4 (applicable to Overtemperature N-16 function). The response times of RCS Cold Leg RTD and OTN16 RTD instrumentation is changed from 6.0 and 3.3 seconds to 6.7 and 3.3 seconds respectively. However, this does not change the overall OTN16 RTD response time requirement of 9.3 seconds and therefore has no adverse affect on the operation of the Tcold RTD signal or the existing safety analyses for the OTN16 function since the safety analyses is insensitive to a trade-off between the RTD response time and the instrumentation response time. Therefore, there is no change to overall response time of 9.3 seconds assumed in the applicable safety analyses.

LDCR-SA-2015-1, EV-CR-2015-000856-1 (SCD):

Additional information will be added to show the new spent fuel pool swing gate equipment. LDCR SA-2014-012 added multiple changes to table 17A-1 and it was found that the addition to system 16 was incorrect and needs to be removed.

Paragraph added to section to describe the passive nature of the refueling gate seals.

LDCR-SA-2015-4, EV-CR-2011-013548-1 (JEB):

ISFSI Security Plan and Cyber Security Plan have been added to the CPNPP security program. Update FSAR to include the new plans by simplifying the section 13.6 statement to make it inclusive of all the plans called for in 10CFR73:

Proposed Wording:

A comprehensive security program has been developed at CPNPP in accordance with the requirements of applicable portions of 10CFR73, "Physical Protection of Plants and Material." The security plans that describe the program contain security related information (SRI) or safeguards information (SGI) and are withheld from public disclosure in accordance with 10CFR2.390 or 10CFR73.21. The CPNPP security plans are presented in separate submittals.

LDCR-SA-2014-23, EV-CR-2010-004331-98 (RAS):

Add the following description for the AFW valves: "The three AFW valve are normally de-energized to prevent a fire induced hot-short from causing a mal-operation of the valve(s). This also de-energized position indication in the Control Room. Therefore, these valves are "Locked Closed" to provide positive indication of correct valve position during normal operation."

LDCR-SA-2015-7, EV-CR-2014-012820-1 (SCD):

This LDCR is a clarification of information in Section 6.5.1.1, which states "Efficiencies of the HEPA filters and iodine adsorbers are in accordance with Table 9.4-4." Testing of the HEPA filters following significant painting, a fire or chemical hazard ensure compliance with the efficiencies in Table 9.4-4. FSAR Table 6.5-1 is revised where Regulatory Guide 1.52, Revision 2 is used by CPNPP rather than Revision 1.

LDCR-SA-2014-28, EV-CR-2014-005590-3 (JDS):

The results obtained from ANSYS version 14.0 for 24 of the 26 problems compared were found to have exact numerical matches to those obtained from version 13.0. The results from the 2 problems that did not match were further evaluated for the significance of their mismatches. The detailed evaluation of these 2 problems found that the results from one differed by less than 1-percent which is the ANSYS expected analytical tolerance. A reviewof the input script for the second problem discovered that the version 14.0 input script was different than what had been used in version 13.0. When the script used for version 13.0 was evaluated by ANSYS version 14.0, it was found to differ by less than 1-percent which is the expected ANSYS analytical tolerance. The input script is user provided input that describes the analytical problem to be solved by the program. A change to the input script is not a change to the program. A review of changes made by ANSYS did not find that any significant issues or problems had been corrected in version 14.0. It is therefore the conclusion of this Evaluation that the analysis results obtained from ANSYS version 14.0 are essentially the same as those obtained from ANSYS

LDCR-SA-2014-28, EV-CR-2014-005590-3 (JDS) (continued):

version 13.0 and ANSYS version 14.0 is not considered a departure from a method of evaluation described in the UFSAR.

LDCR-SA-2015-8, EV-CR-2015-000067-6 (JDS):

FSAR section 9.1.3.2 currently states that the SFP Boron concentration is "approximately the same" as the RWST. As described in EV-CR-2015-000067-1, it is desired to maintain the Spent Fuel Pool boron value between 2600-3000 ppm. The RWST is normally maintained 2400-2600 ppm, which is the TS limit applicable in MODES 1-4 of operation, during which SFP and RWST water do not mix. In Emergency Operating procedures, guidance exists to fill the RWST from the SFP during beyond-design-basis events. As described in EV-CR-2015-000067-1, the boron concentration of this emergency water source does not need to satisfy the normal RWST TS limits, but has its own Technical Specification requirement and SFP water at a boron concentration of up to 3000 ppm remains a valid source of water during this potential beyond-design-basis event.

LDCR-SA-2015-10, EV-CR-2012-011869-1 (JDS):

Revise Section 6.2.2.2 to reference a single table 6.2.1-9, as Tables 6.2.1-9A and 6.2.1-9B have been combined into a single table in Amendment 103 (LDCR-2008-013).

Revise 6.3.2.8 to remove obsolete information (references to Appendix 4A and 4B which were previously removed in LDCR-SA-2008-013) and provide an appropriate reference to Tables 6.2.1-9 and 6.2.1-12.

ReviseTable. 6.3-7 to remove obsolete information (references to Appendix 4A and 4B which were previously removed in LDCR-SA-2008-013) and provide an appropriate reference to Tables 6.2.1-9 and 6.2.1-12.

Delete the last sentence on the page since Cycle/Unit specific information for Units 1 and 2 is no longer provided in Appendices 4A and 4B as these Appendeces were previously removed in LDCR-SA-2008-013.

LDCR-SA-2015-12, EV-CR-2015-006885-2 (SCD):

6.3
In the PSAR (RESAR 3), passive failures were considered coincident with hot leg recirculation at 24 hours. The FSAR originally assumed hot leg recirculation at 24 hours; however, that has changed over time without addressing if the passive failure timing. FDA-2015-000095-01 clarifies the DBD based on the conclusion that the passive failure was considered at switchover to hot leg recirculation and that would be the current licensing basis. Therefore, the FSAR should be updated in accordance with 10CFR50.71(e).

LDCR-SA-2015-13, EV-CR-2015-002140-2 (GLM):

9.2-2
In the last paragraph, correct the CCW fouling factor from 0.0017 to 0.0020.

Justification
Errors were made in previous LDCRs (LDCR-SA-2001-021 and LDCR-SA-2010-001) as described in AI-CR-2015-002140-1. LDCR-SA-2001-021 defined the design fouling as 0.0020 with no plugging and 0.0015 with the plugging allowance. Plugging allowances are no longer used nor are they required. LDCR-SA-2010-001 changed the design fouling factor in two places (not all) and did not change the factor with plugging. The 10CFR50.59 basis for the 2010 LDCR was FDA-2006-003080-01 and -02. These FDAs discuss fouling; HOWEVER, they did discuss a change in the design fouling factor. The actual design fouling factor was not changed. Calculation RXE-LA-CPX/0-018 R8 dated 10/28/08 was performed at the design fouling of 0.002. Calc RXE-LA-CPX/0-018 R9 for power uprate did not change the design fouling; however, it noted it would exceed the 135F limit on the operating unit during a two train CCW outage on an outage unit. Per the attached email and RXE-LA-CPX/0-018 R9, the current design fouling remains 0.002. RXE-LA-CPX/0-020 Rev. 9 for power uprate used a fouling factor of 0.0017 for the single train forced cooldown. The reduction was made to maintain the normal operating temperature limit of 122 F used for the piping analysis. The subject cooldown would be an abnormal condition no subject to the 122F limit. The impact review CVC for this calc revision was not in conformance with ECE-5.03 or ECE-5.01. This revision was the basis for LDCR-SA-2010-001. This calculation was subsequently revised to make corrections. The current version of RXE-LA-CPX/0-020 is R12 dated 11/12/2013 and the design fouling of 0.0020 has been restored. STA-734, Service Water System Fouling Monitoring Program, includes the actual number of plugged tubes in the monitoring based on calculation ME-CA-0229-2188. Plugging limits are not used.

Therefore, correction of the design fouling factor and the deletion of the plugging allowance are required to update the FSAR to be current as required by 10CFR50.71€.

9.2-3
In the first paragraph, correct the CCW fouling factor from 0.0017 to 0.0020. Delete the first and third sentences. In the last sentence, insert the word "fouling" between "periodic" and "monitoring."

LDCR-SA-2015-13, EV-CR-2015-002140-2 (GLM) (continued):

Justification
Errors were made in previous LDCRs (LDCR-SA-2001-021 and LDCR-SA-2010-001) as described in AI-CR-2015-002140-1. LDCR-SA-2001-021 defined the design fouling as 0.0020 with no plugging and 0.0015 with the plugging allowance. Plugging allowances are no longer used nor are they required. LDCR-SA-2010-001 changed the design fouling factor in two places (not all) and did not change the factor with plugging. The 10CFR50.59 basis for the 2010 LDCR was FDA-2006-003080-01 and -02. These FDAs discuss fouling; HOWEVER, they did discuss a change in the design fouling factor. The actual design fouling factor was not changed. Calculation RXE-LA-CPX/0-018 R8 dated 10/28/08 was performed at the design fouling of 0.002. Calc RXE-LA-CPX/0-018 R9 for power uprate did not change the design fouling; however, it noted it would exceed the 135F limit on the operating unit during a two train CCW outage on an outage unit. Per the attached email and RXE-LA-CPX/0-018 R9, the current design fouling remains 0.002. RXE-LA-CPX/0-020 Rev. 9 for power uprate used a fouling factor of 0.0017 for the single train forced cooldown. The reduction was made to maintain the normal operating temperature limit of 122 F used for the piping analysis. The subject cooldown would be an abnormal condition no subject to the 122F limit. The 9.2-3 impact review CVC for this calc revision was not in conformance with ECE-5.03 or ECE-5.01. This revision was the basis for LDCR-SA-2010-001. This calculation was subsequently revised to make corrections. The current version of RXE-LA-CPX/0-020 is R12 dated 11/12/2013 and the design fouling of 0.0020 has been restored. STA-734, Service Water System Fouling Monitoring Program, includes the actual number of plugged tubes in the monitoring based on calculation ME-CA-0229-2188. Plugging limits are not used.

Therefore, correction of the design fouling factor and the deletion of the plugging allowance are required to update the FSAR to be current as required by 10CFR50.71€.

LDCR-SA-2015-15, EV-CR-2015-007540-5 (GLM):

9.2-3
After the last sentence in Section 9.2.1.2.2, add clarification that more restrictive limits are imposed on SSI temp and CCW Hx fouling on the operating unit during outages.

Technical Justification: CCW design fouling and fouling monitoring are described in the FSAR for all normal and accident conditions. However, during the abnormal condition where the CCW on an outage unit is unable to provided cooling to common shared loads, the operating unit is capable of cooling the essential loads. However, restrictions on valve alignments, SSI temperature and/or CCW heat exchanger fouling may be imposed to assure operability is not affected. It may be neccesary to limit the number of supplied components to protect the CCW pumps. CR-2014-007235 is an example of such precautions taken. FDA-2014-000175-01 clarified DBD-ME-229 for the alignment of both spent fuel pool heat exchangers to one unit.

FSAR Amendment 107

LDCR-SA-2015-15, EV-CR-2015-007540-5 (GLM) (continued):

9.2-7
In the last sentence on the page, add the word "normally" between "is" and "required." After the last sentence on the page, add clarification that during outages it may be necessary to take both safeguards trains and/or the non-safeguards loop of CCW out of service for maintenance. In this case, the common components are cooled by the operating unit. In this abnormal alignment, more restrictive limits may be imposed as described in Section 9.2.1.2.1.

Technical Justification: CCW design fouling and fouling monitoring are described in the FSAR for all normal and accident conditions. However, during the abnormal condition where the CCW on an outage unit is unable to provided cooling to common shared loads, the operating unit is capable of cooling the essential loads. However, restrictions on valve alignments, SSI temperature and/or CCW heat exchanger fouling may be imposed to assure operability is not affected. It may be neccesary to limit the number of supplied components to protect the CCW pumps. CR-2014-007235 is an example of such precautions taken. FDA-2014-000175-01 clarified DBD-ME-229 for the alignment of both spent fuel pool heat exchangers to one unit.

LDCR-SA-2015-18, EV-CR-2014-013507-2 (SCD):

In the FSAR Table 6.3-3 Sheet 2 of 3, in the "Valve Identification" column for the Charging pump miniflow isolation valves it lists the valve numbers as "8810 and 8111". This is incorrrect, it should be "8110 and 8111".

Technical Justification:
Administrative change to correct error in valve identification.

LDCR-SA-2015-16, EV-CR-2015-008796-1 (SCD):

Clarify QA review of procedures in SORC.This is to support removal of ODA's and MDA's from SORC approval IAW EV-CR-2013-001259-1.

LDCR-SA-2015-17, EV-CR-2015-000973-2 (GLM):

Description of Change: Delete reference to Figure 9.3-3 on List Of Figures (Page 9-xiv).

Technical Justification: Flow diagrams M1-0216-01 and M2-0216-B were changed from referencing FSAR Figure 9.3-3 to referencing FSAR Figure 9.3-1 in CR 2014-008461. This change updates the List Of Figures to reflect this.

FSAR Amendment 107

LDCR-SA-2014-4, EV-CR-2012-0002652-27 (CBC):

The FSAR is updated to reflect changes to the plant and plant site required by NRC Orders EA-12-049 and EA-12-051. These changes are for “Beyond-Design-Basis External Events” and are not used nor credited by the current plant design basis. Section 1.2 is updated to reflect a general description of NRC Orders EA-12-049 and EA-12-051. Figure 1.2-1 is updated to show the site contains a FLEX Storage Building. The FLEX Storage Building protects equipment credited for NRC Order EA-12-049. Sections 9.1.3.2 (System Description) and 9.1.3.5 (Instrument Requirements) are updated to reflect the addition of the Spent Fuel Pool Level Instrumentation. FSAR Tables 17A-1 and 17A-2 are updated to reflect the quality assurance attributes of the Spent Fuel Pool Level Instrumentation.

LDCR-SA-2014-27, EV-CR-2014-012821-1 (JDS):

Section 6.2-3: Add a sentence that reflects that the temperature and pressure profiles utilized for EQ evaluations as described in section 3.11B bounds the limiting temperature and pressure transients for postulated LOCA and MSLB events. The sentence describes the relationship between containment integrity and environmental qualification. This addition ensures that changes to the containment integrity analysis will consistently cascade to the EQ analysis.

FSAR Table 6.2.1-2 describes CPNPP’s compliance with GDC-16 and -50 that the peak calculated containment pressure should be less than the containment design pressure of 50 psig following a LOCA and is based on the double-ended hot leg (DEHL) and double-ended pump suction leg (DEPS) breaks assuming minimum and maximum ECCS performance (MINSI and MAXSI) cases analyzed by Westinghouse using the EPITOME code. NSAL 14-2 identified errors in the LOCA M&E release analyses input modification program database and the input preprocessor. The analyses are sensitive to energy stored in the RCS metal, including the SG tubes and the program was using the density for stainless steel in determining the mass of the SG tubes and the stored energy based on a stainless steel specific heat. CPNPP steam generators are Alloy 690 (U1) and Alloy 600 (U2) which have different specific heat values than stainless steel. RXE-LA-CPX/0-106 “Impact of M&E Analysis Errors on CPNPP Post LOCA Containment Pressures and Temperatures Meeting Acceptance Criteria” determined that the pressure penalty is 0.2 psi and the temperature penalty is 0.3°F. These penalties were applied to the peak pressure and temperature values in the attached markup of Table 6.2.1-2.

The note added to Tables 6.2.1-2 and 6.2.1-2A as well as Section 6.2.1.1.3.2 describes the relationship between containment integrity and environmental qualification. This addition ensures that changes to the containment integrity analysis will consistently cascade to the EQ analysis.

FSAR Amendment 107

LDCR-SA-2015-19, EV-CR-2015-011212-1 (SCD):

Changes to CPNPP organizational structure due to management changes and restructuring.

FSAR Amendment 108

LDCR-SA-2016-06, EV-CR-2015-011847-1 (SCD):

Editorial change removing date from RG 8.7 reference on page 12.5-10

LDCR-SA-2015-11, EV-CR-2015-000483-2 (CBC):

FSAR Section 5.4.1.2 Item 2 is updated to provide a functional description of the SHIELD Shutdown Seal (SSDS) component.

FSAR Section 5.4.1.3.1 is updated to describe the test program for the SHIELD Shutdown Seal (SSDS), and discuss the RCS and RCP design functions that have been demonstrated as not impacted by implementation of the SSDS.

FSAR Section 5.4.1.3.2 is updated to state that actuation of the SHIELD Shutdown Seal (SSDS) on a reactor coolant pump that is still rotating will not have any measurable effect on the reactor coolant pump coastdown.

FSAR Section 5.4.1.3.4 is updated to state that actuation of the SHIELD Shutdown Seal (SSDS) on a reactor coolant pump that is still rotating will not effect the cooling flow to the reactor core.

FSAR Section 5.4.1.3.10 is updated to provide a description of the timeline of changes within the RCP after a “loss of all seal cooling” that result in the actuation of the SHIELD Shutdown Seal (SSDS) and how the SSDS actuates.

FSAR Section 9.3.4.1.2.1 is updated to provide a description of SHIELD Shutdown Seal (SSDS) activation due to “loss of all seal cooling” to limit RCP seal leakoff and to describe that should the RCP continue to run, that the SSDS is assumed to fail to limit leakoff.

FSAR Section 9.3.4.1.3.1 is updated, similar to Section 9.3.4.1.2.1, to provide a description of SHIELD Shutdown Seal (SSDS) activation while the RCP continues to run, that the SSDS is assumed to fail to limit leakoff, which is a RCS letdown flowpath.

FSAR Table 17A-1 is updated to provide a quality classification for the SHIELD Shutdown Seal (SSDS) note within the description of the RCP No. 1 Seal Housing and a new note to FSAR Table 17A-1.

LDCR-SA-2016-4, EV-CR-2014-005127-1 (CBC):

References to FSAR Figure 6.2.2-1 and Table 17A-1 are added to the text discussion. FSAR Section 6.2.2.2.1(6) "piping and valves" is clarified. These changes are clarifications to provide consistency within the FSAR.

LDCR-SA-2017-1, EV-TR-2016-008360-22 (SCD):

Wording change to describe General Employee Training after implementation of NEI Bulletin 16-26b.

FSAR Amendment 108

LDCR-SA-2016-3, EV-CR-2015-007215-1 (GWS):

Update the outdated description of the PHOENIX-P cross-section library Change "...42 energy group library, which has been derived mainly from the ENDF/B-V files." to "...70 energy group library, which has been derived mainly from the ENDF/B-VI files."

Comanche Peak began using the PHOENIX-P methodology as part of the reload safety analysis transition to Westinghouse that was reviewed and approved by the NRC in License Amendment 144 which was implemented beginning with Unit 2 Cycle 11 in the Spring of 2008. The UFSAR changes made to implement License Amendment 144 were done in conjunction with those to implement the power uprate (License Amendment 146) (UFSAR Amendment 103, LDCR SA-2008-13, EV-CR-2006-003080-00-94) and incorrectly used the outdated description of PHOENIX-P as using the 42 energy group ENDF/B-V libraries. Note that the License Amendment Request for the power uprate (LAR 07-004) included the correct description of the 70 energy group library based on the ENDF/B-VI files (WCAP-16840/enclosure 1 of TXX-07106) which was reviewed and approved by the NRC in License Amendment 146. This LDCR simply corrects an error in originally incorporating the previously approved change (License Amendments 144 and 146).

LDCR-SA-2016-2, EV-TR-2016-000825-1 (GLM):

Update Section I.C.5 to reflect the current CPNPP OE program.

LDCR-SA-2016-019, EV-CR-2010-008411-28 (JCH):

Delete Vacuum Breakers CP1/2-SWVAVB-03/04 from Table 3.9B-10 (Sheet 14 of 22)

LDCR-SA-2016-014, EV-CR-2015-008517-18 (KJV):

3.5.1.4 - Update to Turbine Driven Aux Feedwater (TDAFW) exhaust stack tornado missile analysis. Changes previously made by LDCR-SA-2013-04 which credit the Motor Driven Auxillary Feedwater Pumps providing the auxiliary feedwater design function following a tornado missile strike are deleted. New information which addresses the impact of tornado missiles on the Main Steam System supply and exhaust for the Turbine Driven AFW pump and the effect on the entire AFW system is inserted in its place.

10.4.9.3 - Clarify missile protection and describe the CST vents consistent with Sections 3.5.1.4, 9.2.6 and 10.4.7.1. Add a description of the Turbine Driven AFW Pump steam supply and exhaust and cross reference Section 3.5.1.4.

LDCR-SA-2017-007, EV-TR-2016-010272-1 (CBC):

Revise Section 1A(B) discussion of RG 1.01, "Emergency Planning for Nuclear Power Plants," to document use of NEI 99.01 Revision 6 for Emergency Action Level (EAL) development. CPNPP adopted and implemented EALs based on the NRC-endorsed guidance in NEI 99-01-R6 (NRC License Amendment 166 - ML16137A056 and ML16168A002).

FSAR Amendment 108

LDCR-SA-2016-008, EV-CR-2015-007780-6 (SCD):

T 11.5-2 - This change is being made due to new information received from the vendor with design authority, General Atomics (GA). Documentation received from GA (Ref. VDRT-5243381) states that the detectors located downstream of the sample pumps are limited to an extreme maximum operational temperature of 140 °F. A note is being added in lieu of changing the actual temperature value in FSAR Table 11.5-2 because this VDRT is only applicable to the gas detectors, not the whole gaseous channel associated with each detector.

SA-2017-005 EV-CR-2017-007035-1 (GWS):

15.1-9 - Currently the FSAR sates, “No credit is taken for the proper of the non-Class 1E steam dump solenoid valves when the low-low T_{avg} (P-14) setpoint was exceeded.” The actual low-low T_{avg} signal is P-12. P-14 replaced with P-12.

SA-2013-025 EV-CR-2010-004331-95 (JCH):

Description: Added the following valves to Table 7.4-1 on Sheet 6 of 6:
- Identification: LCV-0112B; Function: (d) Motor-driven Charging Pump-Suction Pressure
- Identification: LCV-0112D; Function: (d) Motor-driven Charging Pump-Suction Pressure

Justification: Installed new control switches on the Hot Shutdown Panel (1-LV-01 and 2-LV-01) for LCV-0112B and LCV-0112D to allow control of these valves from the Hot Shutdown Panel. This will isolate the portions of the control circuit that is routed in the Control Room and the Cable Spread Room.

Description: Added the following valves to Table 7.4-3 on Sheet 3 of 3:
- Identification: LCV-0112B; Function: (b) Motor-driven Charging Pump-Suction Pressure
- Identification: LCV-0112D; Function: (b) Motor-driven Charging Pump-Suction Pressure

Justification: Installed new control switches on the Hot Shutdown Panel (1-LV-01 and 2-LV-01) for LCV-0112B and LCV-0112D to allow control of these valves from the Hot Shutdown Panel. This will isolate the portions of the control circuit that is routed in the Control Room and the Cable Spread Room.

SA-2016-016 EV-TR-2015-010416-33 (CBC):

Section 1, 1.1, 1.4, T1.4-1 (including Table of Contents and List of Tables) - This section is updated to be consistent with NRC License Amendments 167 and 169 (transfer of Operating Licenses to Comanche Peak Power Company LLC (owner) and Vistra Operations Company LLC (operator)). Section 1.4 is updated to remove historical information and level of detail not required for this section. Table 1.4-1 is below the level of detail for this section and is deleted.

SA-2016-016 EV-TR-2015-010416-33 (CBC) (continued):

Sections 1A(B), 2.1, 2.3, 3.7B, 3.11B, 3A, T4.1-1, 6.6, 7.1, 7.2, 8.3, 9.5, 11.3, 11.4, 11A, 12.1, 12.4, 13.1, 13.5, 14.2, 15.3, 15.6, 17.1, 17.2, T17.2-2, 17A, III.A - These sections are updated to be consistent with NRC License Amendments 167 and 169 (transfer of Operating Licenses to Comanche Peak Power Company LLC (CP PowerCo) (owner) and Vistra Operations Company LLC (Vistra OpCo) (operator)). Most of the FSAR sections will refer to Vistra OpCo. CP PowerCo is used within the context of financial responsibility (e.g., decommissioning costs) or property ownership (e.g., mineral rights).

SA-2017-012 EV-CR-2016-007216-2 (CBC):

Table 5.4-16 - “Pressurizer Valves Design Parameters,” indicates that each of the two pressurizer power operated relief valves (PORVs) has a steam relieving capacity of 210, 000 lb/hr at 2235 psig. The pressure is changed from “2235” to “2335” for consistency with CPNPP design basis and the background discussion of Technical Specification Bases 3.4.11 “Pressurizer PORVs”. This is an editorial change correcting a typographical error.

SA-2015-002 EV-TR-2014-003190-4 (GLM):

Revise section 9.2.3.1 to reflect current chemistry control methodology and delete Tables 9.2- 9 and 9.2-10

Information in Tables 9.2-9 and 9.2-10 is not current with industry and CPNPP practice. The details are not necessary in the FSAR, and are contained in the Chemistry Data Sheets, CHM- 140-507-1 and CHM-140-507-2. A discrepancy exists between the specific conductivity limit for the Demineralized Water Storage Tank on chemistry form CHM-140-507-1 and the requirement documented in DBD-ME-241 "Demineralized and Reactor Makeup Water System" and FSAR, Section 9.2. This is acceptable because the DBD chemistry parameters are the specifications that the equipment was originally designed to, while the values in chemistry procedures and the Primary Chemistry Strategic Plan are based on recommendations from EPRI and Westinghouse which evolve to improve plant performance. Early in plant life, chemistry control was conducted in accordance with the design values specified in the DBD. When chemistry control methodology changed neither the DBD nor the FSAR was updated. A review was performed of the chemistry restrictions encompassed in DBD-ME-241 and FSAR Section 9.2. It also included CHM-140-507-1 and CHM-140-507-2, the chemistry procedure forms corresponding to DBD-ME-241 Attachment 1 and Attachment 2, respectively. A review of FSAR Section 9.2 found that chemistry restrictions have not been updated to correspond with the plant practice of following EPRI and Westinghouse guidance.

SA-2015-002 EV-TR-2014-003190-4 (GLM) (continued):

FSAR Table 9.2-9 presents chemistry restrictions for Demineralized Water and FSAR Table 9.2-10 presents chemistry restrictions for Reactor Makeup Water. These restrictions are not in conformance with Westinghouse guidance on the location of sampling or requirements for monitoring. For example, the FSAR states that "the quality of water in the Demineralized Water Storage tank is consistent with the water chemistry listed in Table 9.2-9"; however, the Westinghouse guidance specifies that the monitored values should be measured at the outlet of the water treatment plant rather than the tank itself. Also, the guidance does not require plants to monitor this value if, like CPNPP, it has not been incorporated into Technical Specifications.

Removing the outdated tables will ensure that information discrepancies don't occur in the future as data sheets are updated to keep up with changing chemistry guidelines and water conditions.

SA-2016-018 EV-TR-2016-002219-1 (SCD):

Section 13 Table of Contents and List of Figures:
The TOC is updated to reflect deletion of Appendix 13.1A and the LOF is updated for consistency with NRC License Amendments 167 and 169.

Section 13.1:
This section is updated to align with the current CPNPP organizational structure.

Appendix 13.1A:
Appendix 13.1A is deleted. The resumes of current key personnel are available upon request.

Figures 13.1-1, 13.1-2 and 13.1-3:
Updated figures to show current reporting reporting relationships and titles. Figure 13.1-1 is updated to be consistent with the license transfer associated with NRC License Amendments 167 and 169

SA-2017-004 EV-CR-2016-006853-3 (KJV):

Appendix 5A:
FSAR Appendix 5A is clarified to document the full environmental qualification of the PORVs that bound the worst case BTP RSB 5-1 shutdown. Confusion regarding compliance with BTP RSB 5-1 as described TXX-89204 (dated 5/19/89) is reflected in SSER 22 (additional details in FDA-2017-000084-01). Subsequent to the SSER, the PORVs were environmentally qualified for a harsh environment. This new information is added to the FSAR Appendix 5A to effectively supersede TXX-89204 and SSER 22 in accordance with 10CFR50.71(e).

FSAR Amendment 108

SA-2017-014 EV-TR-2017-007340-1 (CBC):

Sections 10.2.2.7, 10.2.2.7.1:
FSAR Sections 10.2.2.7 and 10.2.2.7.1 are revised to remove frequency influence turbine control features which have never been used at CPNPP. Frequency Influence is a feature of the turbine controls which has never been turned on at CPNPP. Frequency influence is grid frequency control. If turned on, the CPNPP turbine-generator EHC turbine load control would regulate the turbine steam valves in an attempt to control grid frequency at 60 hz +/- 0.05 hz. This would constantly impact reactivity; therefore, CPNPP has always been a base load unit with the fossil plants controlling grid frequency. The EHC turbine control is speed/load control only with frequency influence turned OFF. Since Frequency Influence must always be turned off, and the existing operation and monitoring (OM) system has never had these functions (no need to have an Operator capability on the operation and monitoring (OM) system to turn it on or impact it in any way).

SA-2016-010 EV-CR-2016-003267-8 (KJV):

Section 5.4.12:
Clarification provided for unit difference for lower instrument taps on pressurizer level instruments lower taps. Specifically, 1RC-8054A, B, and C are upstream of the reducing orifice whereas on Unit 2 the valves are downstream of the orifices. This configuration has existed since initial construction. This change is supported by 10 CFR 50.59 evaluation EV-CR-2016-003267-10.

Tables 5.2-3 and 5.2-7:
Revised to reflect unit difference and associated valve qualifications.

2017-008 EV-TR-2017-007342-1 (SCD):

Chapter 17
Revise FSAR Chapter 17 to address Nuclear Oversight organization, titles, and qualification changes.

2017-009 EV-CR-2017-001654-1 (KJV):

Appendix 9.4A:
Section 9.4A.2.1, “Containment Recirculation and Cooling System,” is revised to reflect a new modification (i.e., FDA-2013-000133-03) allowing use of silencers in the Unit 2 Containment Recirculation Cooling System during Cold Shutdown and Refueling (or when the core is offloaded). The purpose of this modification was to alleviate heat stress and reduce noise during outages.

Table 17A-1:
Table 17A-1 is updated to reflect use of silencers for Unit 2 Containment Recirculation and Cooling System as described in Section 9.4A.2.1.

FSAR Amendment 108

2017-015 EV-TR-2017-007709-1 (SCD):

App. 1A:
Add Reg Guide 8.10 and exception to Appendix 1A(B).

SA-2017-006 EV-CR-2012-009889-5 (CBC):

Section 3.4.2:
FSAR Section 3.4.2 is updated to describe the historical change in design-basis hydrostatic water level used in the design of safety-related structures. The change in hydrostatic water level was reviewed and documented by the NRC in SSER 25. This is an acceptable editorial change required for consistency with FSAR section 2.4.13.5 and SSER section 2.4.6. Previous ground water levels were retained for historical purposes.

SA-2017-013 EV-TR-2012-007391-1 (GWS):

Update of Section 10.4.3 to Feedwater Pump Turbine Gland Seals following FDA-2005-004990-01 (Unit 1 modification) and FDA-2005-004990-02 (Unit 2 modification).

SA-2017-011 EV-TR-2015-002656-2 (KJV):

Section 5A:
Corrects description of BTP requirement I.2 and II.1 for Cold Shutdown in 36 hours. RHR operational conditions is HOT SHUTDOWN, not COLD SHUTDOWN. This is a correction. BTP RSB 5-1 requires cold shutdown conditions in a reasonable period of time which means cold shutdown be expected to be reached in 36 hours.

SA-2016-009 EV-TR-2016-001674-6 (KJV):

8.2-3 & 8.2-7:
Revision to reflect renaming of DeCordova 345 KV line to Mitchell Bend.

Figure 8.2-1:
Revision to reflect renaming of DeCordova 345 KV line to Mitchell Bend.

Figure 8.2-4:
Revision to reflect renaming of DeCordova 345 KV line to Mitchell Bend.

Figure 8.2-12:
Revision to reflect renaming of DeCordova 345 KV line to Mitchell Bend.

FSAR Amendment 108

SA-2017-003 EV-CR-2016-004078-7 (KJV):

Section 3.5.1.4:
Clarifies discussion in FSAR Section 3.5.1.4 that the portions of the SSW discharge piping is not protected from a design basis missile impact but has been evaluated to show the SSW would perform it's safety function during and after a design basis tornado.

Section 9.2.1.4:
Is updated to note that the impact of tornado missiles on the SSW intake trash racks, traveling screens, and a small portion of discharge piping are discussed in further detail in Section 3.5.1.4.

Section 9.2.2.1:
Clarifies the operation / alignment of CCW during planned maintenance in outages.

Section 9.2.2.2.1:
Clarifies the operation of CCW during and after LOCA by noting restrictive limits on the nonsafeguards loop from the accident unit.

SA-2012-003 EV-TR-2009-005301-19 (KJV):

Figure 1.2-1:
Existing layout drawing revised to delete excessive and out of date information regarding switchyard configuration. Configuration is described in FSAR Section 8.

Section 8.2:
Revision made to reflect installation of 8075 breaker.

FSAR Amendment 108

SA-2015-014 EV-TR-2014-009974-1 (KJV):

15.6-6,8:
Update FSAR Section 15.6.3 to incorporate impacts of re-analyis of SGTR margin to overfill in response to NSAL 07-11. The CPNPP Steam Generator Tube Rupture (SGTR) margin-tooverfill analysis was revised by Westinghouse to demonstrate that margin to overfill exists (WPT-17834). The analysis was performed by the RETRAN using conservative assumptions to demonstrate the ability of the operator to limit the system transient and establish parameters for providing a bounding radiological consequence assessment. Important operator actions in the CPNPP emergency operating procedures were explicitly modeled in the analysis. the design input for the delivery time of Auxiliary Feedwater (AFW) to the steam generators was revised to more accurately reflect actual plant response. In the initial SGTR margin-to-overill analysis, Auxiliary Feedwater was delivered instantaneously to the steam generators concurrent with reactor trip. However, on a loss of off-site power, the turbine-driven AFW pump start automatically on a blackout signal and the motor-driven AFW pumps are sequenced to their respective power supplies. The start of the TD AFWPs on a blackout signal may be considered instantaneous; however, there is a 40 second delay for the MD AFWPs as the blackout sequencer establishes loads. A review of surveillance data for the TD AFWPs along with the consideration of the power supply alignment for the MD AFWPs determined that a 30 second delay for delivery of AFW to the SGs was conservative. This was modeled in the analysis as a delay in the actuation of AFW. The operator action to terminate Safety Injection thus increased from the current FSAR value of 2 minutes to 3 minutes.

SA-2017-016 EV-TR-2014-009429-1 (GWS):

9.2-1:
Added that during a loss of all Station Service Water, the Fire Protection water system may be aligned to cool the emergency diesel generator jacket water heat exchangers and the safety injection and centrifugal charging pump lube oil coolers.

SA-2016-012 EV-TR-2016-007332-2 (CBC):

F1.2-1:
FSAR Figure 1.2-1, "Plot Plan," is revised to remove the "TEMP SECURITY" box outside of the Southeast corner of the RCA Yard fence inside the Protected Area. This "TEMP SECURITY" box is below the level of detail required in the FSAR.

FSAR Amendment 109

SA-2011-009 EV-CR-2010-004331-93 (JCH):

Sections 8.3.1.4, 8.3.1.4.5, 9.5.1.2.2, and 9.5.1.5.5:
Updates text to reflect use of three-hour Thermo-Lag. Thermo-Lag is an intumescent fireproofing system. It was designed to provide 1 to 3-hour fire protection for various applications. Previously, CPNPP utilized only 1-hour Thermo-Lag. In order to ensure safe reactor shutdown during a fire, CPNPP requires the use of three-hour Thermo-Lag for a fire scenario outside the Control Room. FDA-2010-000172-11-04 provides testing and specifications demonstrating 3-hour ThermoLag's ability to resist a three-hour fire.

SA-2013-016 EV-TR-2012-005259-78 (JCH):

Section 9.5.1.5.6:
Revised to add new startup transformer XST1A to the list of transformers that are separated from the Turbine Buildings by a three hour fire wall.

SA-2014-010 EV-TR-2014-005538-3 (KJV):

Table 8.3-3 and Section 8.3:
Addition of alternate startup transformers XST1A and XST2A for off-site power sources.

SA-2017-002 EV-TR-2016-009440-4 (JCH)

Update Table 10.4-10 Sheet 3 to reflect new TPCW Heat load from new H2 Gas Dryer in support of FDA-16-000081-01. Value changes from .0051 to .0055.

SA-2017-010 EV-TR-2017-009826-1 (GWS):

Section 9.1.4.2.3:
Update description of the Fuel Handling Bridge Crane (FHBC) and load cell to reflect design Modification FDA-2016-000014-03 which eliminates use of an in line load cell.

SA-2017-017 EV-TR-2017-008401-1 (GWS):

Add drawing M2-0211-02 to Title for Figure 10.4-3 on Page 10-viii.

SA-2017-019 EV-TR-2017-009826-2 (GWS):

Sections 3.11B, 3A, Tables 7.5-7A, 7.5-7B, and 7.5-7C:
Clarification of the equipment qualification program scope for harsh and for mild program equipment.

SA-2017-020 EV-CR-2015-009663-2 (KJV)

Table 15.1-3:
Incorporate changes to MSLB dose consequence analysis per WPT-17889.

FSAR Amendment 109

SA-2017-021 EV-TR-2017-009826-4 (GWS):

Table 1.6-2, Sections 3.5.1.3 and 10.2.2.7.6:
Remove the design and analyses information for turbine missiles and revise Testing and Trip Devices to Turbine Valve Testing.

SA-2017-023 EV-TR-2017-010561-1 (GLM):

Update FSAR Sections 9.3.3.2.3 and 9.3.3.2.5 to describe that Auxiliary Building Sump 3 receives drainage from the discharge of the SW tunnel sump pumps and to describe the SW tunnel sumps that will be present in the Fuel Building, respectively.

SA-2017-024 EV-TR-2017-009826-12 (GWS):

Remove jacket water information from lube oil Section 9.5 and replace data in Table 9.5-18.

SA-2017-025 EV-TR-2017-012492-1 (KJV):

Add text to Refueling Section 5.4.7.2.3 that describes alternate reactor core cooling via the safety injection pumps through residual heat removal system.

SA-2017-026 EV-TR-2017-012252-1 (CBC):

Revise Chapter 13, Section 13.1.1.24 to align with commitment 03620 (opportunity to have interview with SAFETEAM).

SA-2018-001 EV-CR-2017-013071-2 (KJV):

Section 8.3.1.1.i1:
Update to EDG voltage control description while on magnetics.

FSAR Amendment 109

SA-2018-003 EV-CR-2016-008855-3 (KJV):

FSAR Section 17A.3 is clarified by changing the title of system 33 from “Fuel Handling Equipment” to “Fuel Handling Equipment and Fuel Assemblies”.

FSAR Table 17A-1 is clarified by changing the title of system 33 from “Fuel Handling Equipment” to “Fuel Handling Equipment and Fuel Assemblies”. The Safety Classification for Fuel Assemblies is corrected from Safety Class 2 to 3. During resolution of CR-2016-008855 (Corrective Action Program document to resolve discrepancy between FSAR and equipment list), Westinghouse advised that Fuel Assemblies are Safety Class 3, not 2, based on ANSI 51.1 (ANSI/ANS 51.1 (1983)). Since Table 17A-1 is based on ANSI N18.2 (see Note 7 of FSAR Table 17A-1) which does not provide a classification for Fuel Assemblies, Note 99 is added to Table 17A-1 to clarify that ANSI 51.1 is used as the basis for Safety Class 3. Since the Fuel Assemblies are not subject to the ASME Code by any regulation, by ANSI N18.2, or by ANSI 51.1 and the assemblies are classified as Safety Related and Seismic Category I independent of this change, the change is merely an administrative correction. However, the change is included in the screening for FDA-2018-000015-01 which corrects the Master Equipment List in Maximo.

SA-2018-004 EV-TR-2017-001152-2 (CBC):

Update (revise) the UFSAR Section 17.2 regarding ORC requirements. Specifically, added NDE and administrative controls to designated review activities, decreased ORC composition from six to five members, specified requirements for ORC meetings being conducted twice per year rather that once per six months, removed two outside member minimum for quorum requirement, and removed redundant requirement to forward audit program reviews to SVP & CNO.

SA-2018-006 EV-CR-2013-008394-74 (KJV):

Section 8.3.2.1:
Remove statement “Non-Class IE loads are not connected to these systems.” This was removed as a clarification to remove the inconsistency with FSAR Section 8.3.2.1 Item (7) (i.e., FSAR Figure 8.3-14 Sheet 6 circuit 10)

Section 8.3.2.1 Item 2.a “Capacity / Batteries”:
The battery capacity for BT1ED2 and BT1ED2 is changed from “1950” to “1944.” The amp-hour rating is revised per manufacture data.

Section 8.3.2.1 Item 2.b “Capacity / Battery Chargers”:
Added “+/-” in front of the tolerance range for float and equalize voltage values. This is an editorial clarification.

FSAR Amendment 109

SA-2018-006 EV-CR-2013-008394-74 (KJV) (continued):

Section 8.3.2.1 Item 7 “Identification of Safety Loads”:
Changes the reference to figures from “Figures 8.3-14 (Sheets 1 & 2) and 8.3-15B (Sheets 1 & 2)” to “Figures 8.3-14 and 8.3-15B”. This is an editorial correction since are no designated “Sheets 1 & 2”. Figures 8.3-14 and 8.3-15B are a compilation of several plant drawings as noted in Table 3.2-4.

Section 8.3.2.1 Item 7 “Identification of Safety Loads”:
Revised the sentence referencing the maximum length of operating time by changing “DC bus” to “battery”. This is an editorial clarification, Table 8.3-4 refers to battery load.

Table 8.3-4, “125-Vdc CLASS IE BATTERY LOAD REQUIREMENTS”:
The table is revised by updating the amperes, clarifying Note 1, and removing Note 2 to reflect approved engineering calculations.

SA-2018-008 EV-TR-2018-002691-1 (CBC):

Revise the Figure 1.2-1 to show the addition of the Stator Assembly Building, X-YD-3K34, south of Warehouse E.

SA-2018-009 EV-TR-2017-009826-3 (GWS):

Sections 9.5.4.2 and 9.5.6.2:
Add clarifying information for fuel oil transfer pumps and starting air systems with regard to emergency diesel generator operability for Technical Specifications 3.8.1, 3.8.2, and 3.8.3.

SA-2018-010 EV-TR-2018-001537-8 (KJV)

Table 1.6-1, Sections 1A(B) and 9.1.4, and Table 17A-1:
Add Wonderhoist to Miscellaneous Handling Equipment.

SA-2018-012 EV-TR-2018-004370-1 (GWS):

Section 7.7.1.3.1:
Add BEACON Axial Offset as a method to measure core power distribution in addition to flux maps made using the movable incore system.

SA-2018-017 EV-CR-2017-010633-29 (KJV)

Revise the discussion regarding ASME Code Case N-31-1 in FSAR Section 1A(B) Regulatory Guide 1.84.

FSAR Amendment 109

SA-2019-001 EV-TR-2017-012914-1 (GWS):

Remove Post Accident Sampling System from FSAR Table 17A-1, List of Quality Assured Structures, Systems, and Components.

SA-2019-003 EV-TR-2017-009826-16 (CBC):

Sections 1A(N), 1A(B), and 17.2.17:
The guidance for electronic storage requirements for Quality Assurance records is updated to reflect the best practices, evolved technology, improvements in electronic record keeping, and more specific details.

FSAR Amendment 110

SA-2016-015 EV-CR-2013-000105-3 (KJV):

Section 8.3.1.1.11.2:
Update FSAR Section 8.3.1.1.11.2 to add additional EDG trip functions described in other design documents. This is an administrative change to the facility documents and the FSAR. This activity will ensure consistency throughout design documents.

SA-2018-007 EV-CR-2017-011125-2 (KJV):

Section 8B:
Revise to allow a two train EDG outage when Technical Specifications allow.

SA-2018-011 EV-TR-2017-001993-5 (GLM):

Update section 3.8.3.1.2 to reflect that 2 keys, instead of 1, are used to satisfy the crane anti-collision interlock function.

SA-2018-014 EV-TR-2016-005840-53 (KJV):

Section 8.2.1:
The text discussion is updated to reflect the open phase condition equipment. This change is consistent with design documentation Final Design Authorization (FDA) numbers 2016-000005-02, 2016-00005-04, 2016-000005-05, and 2016-000005-06.

SA-2018-015 EV-TR-2018-004664-10 (CBC):

Figure 1.2-1:
"Plot Plan," is revised to show the addition of the crane column supports in both Turbine Building crane bay. The crane column supports added to the Turbine Building crane bays for both units were installed solely to support an engineering temporary lift assembly used to replace the main generator stators. They are located within the Protected Area but do not adversely affect any plant SSCs and serve no UFSAR-described function.

SA-2019-002 EV-TR-2017-004085-5 (GWS):

Figures 8.2-1 and 8.2-4:
Multiple new breakers added to switchyard for reliability.

SA-2019-006 EV-CR-2016-009517-2 (GLM):

Section 9.4E.2.1.b:
Clarifies the operation of the NNS chillers during a LOOP. The four NNS chillers are loaded on each of the four diesels by the blackout sequencer and are available to cool both containments, both PDP pumps and the secondary plant sampling package. There is no requirement for all four chillers to operate during a LOOP. This change is consistent with statements FSAR 9.4E.1.

FSAR Amendment 110

SA-2019-007 EV-CR-2019-003268-1 (KJV):

Section 9.5.5.2:
Adds specific reference to pre-licensing Question and Response (Q&R) regarding post-accident leakage from Emergency Diesel Generator jacket water. For consistency, this is an administrative change which adds explicit reference in FSAR section 9.5.5.2 to the questions and responses (Q&R) between the NRC and CPNPP with regard to allowable leakage from the EDG jacket water standpipe.

SA-2019-008 EV-TR-2018-009176-2 (GLM):

FSAR Section 9.2.1.1:
(Station Service Water System / Design Basis) and Section 9.2.5.3(1) (Ultimate Heat Sink / Safety Evaluation) are updated to reflect the results of the revised hydrothermal analysis of the Safe Shutdown Impoundment to include the most current heat loads from engineering calculations.

SA-2019-009 EV-CR-2019-002068-4 (GWS):

Tables 8.3-1 and 8.3-2:
Replace "AUTO SEQUENCER START" with "AUTO SEQUENCER SIGNAL" to be consistent with Technical Specification Bases for SR 3.8.1.11.

SA-2019-010 EV-TR-2018-007152-4 (CBC):

Section 1A(B) RG 1.33 Rev 2:
Removes biennial reviews for Emergency Response Guidelines (ERGs), Functional Restoration Guidelines (FRGs), and Abnormal Plant Operating Procedures (ABNs). The requirement for biennial reviews is replaced with reliance on current programs and processes. The changes are consistent with NRC RG 1.33 Revision 2. This change was approved by the NRC (i.e., CP-201900476 / ML19228A086, CP-202000024 / ML20016A318, and ML20054A276).

Sections 13.5.1, 17.2.1.6, and 17.2.2:
Updates programmatic discussion of procedures. The discussion of procedures is clarified by removing prescriptive, unnecessary, and inconsistent information. The changes are consistent with NRC RG 1.33 Revision 2. The change to the SORC meeting frequency (from once per month to periodically as determined by the SORC chairman or the designated alternate) was approved by the NRC (i.e., CP-201900476 / ML19228A086, CP-202000024 / ML20016A318, and ML20054A276).

SA-2019-015 EV-TR-2019-006425-1 (GWS):

Section 9.1.4.2.3.17:
Added component description for new mechanical (Framatome) RCCA tool to existing component description of the mechanical with an electro-pneumatic winch RCCA tool.

FSAR Amendment 110

SA-2019-017 EV-CR-2019-005757-1 (CBC):

FSAR Sections 12.5, 13.1, 13.3B, and 17.2 and FSAR Figures 13.1-2 and 13.1-3 are updated to reflect the current CPNPP organization relationships and functional responsibility descriptions. This an administrative update.

In accordance with Operating License paragraph 2.G, the changes to CPNPP Fire Protection Program (i.e., FSAR Section 13.3B) do not adversely affect the ability to achieve and maintain safe shutdown in the event of a fire.

In accordance with 10 CFR 50.54, the changes to the Quality Assurance Program (i.e., FSAR Section 17.2) do not reduce the commitments in the QA Program previously accepted by the NRC.

SA-2019-018 EV-CR-2019-005757-9 (CBC):

FSAR Table 13.1-1 is updated to be consistent with approved LDCR-SA-2019-017 / EV-CR-2019-005757-1. This is an administrative update.

SA-2019-020 EV-TR-2019-001318-1 (GLM):

Add note to page 1-vii to state that the Chapter 1 Figure title blocks will not be updated to change “Comanche Peak S.E.S.” to CPNPP. Change CPSES to CPNPP in Section 1.2.4. This is an administrative update.

SA-2019-021 EV-CR-2019-008333-1 (CBC):

Section 13.3B:
(CPNPP Fire Protection Program) included a reference to periodic audits as discussed in FSAR Section 17.2.1.3.2. This reference is incorrect and is changed from "17.2.1.3.2" to "17.2.18". This is an editorial update and does not adversely affect the ability to achieve and maintain safe shutdown in the event of a fire.

SA-2019-022 EV-TR-2019-007125-1 (GWS):

Sections 1A(B), 9.5.4.4:
Update FSAR Appendix 1A(B) to add exception to C.2.f of RG 1.137. Remove detailed description of fuel oil sampling and refer to sampling programs.

SA-2019-023 EV-TR-2020-001500-1 (JEB):

Revise FSAR TMI III.D.3.3 to remove description of EOF-NOSF laboratory facilities.

The description of the EOF-NOSF laboratory facilities in Section 6.7 of the Emergency Plan was deleted. The EOF-NOSF laboratory facilities are no longer maintained as a back-up for iodine analysis. The available back-up lab facilities are described in Section 6.8 of the Emergency Plan.

FSAR Amendment 110

SA-2020-001 EV-TR-2020-001413-1 (CBC):

Figure 7.1-3 (sh 05 of 36):
Figure 7.1-3 (sheet 5 of 33) shows 1-LT-0501, SG Loop 1 Wide Range level transmitter twice and does not show 1-LT-0502, SG Loop 2 Wide Range. The depiction of 1-LT-0501 at the approximate one-o'clock position on the drawing is in error and is changed to 1-LT-0502. The depiction of 1-LT-0501 slightly below the three-o'clock position is correct. This is an editorial correction.

SA-2020-002 EV-CR-2019-004086-2 (CBC):

Table 17A-1:
The seismic classification of Item 41 / Instrumentation & Controls / Seismic Instrumentation of Table 17A-1 is changed from “NONE” to “II” and “Note 100” is added in the Remarks column. Note 100 states “The portion of seismic instrumentation installed in the control room is seismic category II (i.e., seismic monitoring system cabinet).” This change is a clarification and is consistent with the CPNPP design basis.

SA-2020-004 EV-TR-2020-002116-1 (CBC):

Sections 1A(B) (RG 1.33 and RG 1.144), 17.2.7, 17.2.18:
This change updates interval periods for certain QA audits as discussed in Sections 1A(B) (RG 1.33 and RB 1.144), 17.2.7, and 17.2.18. The change adds details regarding grace periods based on conditions (e.g., plant operational considerations, to accommodate supplier activities). This change conforms to the requirements of 10 CFR 50 Appendix B and is consistent with the Section 17.2 of NUREG-0800. This change has been reviewed per 10 CFR 50.54 and does not reduce the commitments or effectiveness of the QA Program (FSAR Chap 17) previously accepted by the NRC.

SA-2020-006 EV-CR-2020-003010-1 (GWS):

Section 7.2.2.3.3:
Correct Pressurizer Pressure coincidence from 2 of 3 to 2 of 4.

SA-2020-007 EV-CR-2017-004389-1 (CBC):

Section 2.4.1.1:
This change updates the discussion in Section 2.4.1.1 which refers to Figures 2.4-4, 2.4-40, and 2.4-41. Site plan drainage configuration changes (placement of new or modified design features, buildings, Security related features and other structures) have been implemented and the design basis updated to reflect these changes and impacts. This change clarifies that although this level of detail is not shown on Figures 2.4-4, 2.4-40, and 2.4-41, the drainage system requirements have been addressed.

FSAR Amendment 110

SA-2020-008 EV-TR-2017-006309-5 (CBC):

Section 2.4.13.2.2:
Updates text discussion to describe the plugging and capping of four production wells (two of which were specifically listed in the FSAR). Also described operational pumpage while the two listed productions wells were used. Four production wells were plugged and capped in 2013 as documented in CR-2012-011569 (LDCR-SA-2013-007). Since 2012 Somervell County Water District became the sole supplier of potable water for CPNPP.

SA-2020-009 EV-TR-2020-005363-1 (CBC):

Sections: 1.1, 1.4.1, 13.1, 17 and Figure 13.1-1
Vistra Operations Company LLC (Vistra OpCo) (operator) and Comanche Peak Power Company LLC (CP PowerCo) (owner) are subsidiaries of Vistra Energy Corp. As part of corporate re-branding, "Vistra Energy Corp." has been changed to "Vistra Corp." This is an editorial change only and has no impact to Comanche Peak Nuclear Power Plant.

SA-2020-010 EV-TR-2019-009288-1 (GWS):

Table 8.3-1:
Revise Note 7 last sentence to read; “See DBD-ME-011, Diesel Generator Sets, Attachment 3 for other DBAs where loss of offsite power is mitigated by the BOS.”

SA-2020-011 EV-TR-2017-004708-6 (CBC):

Updates Table 1.6-1 to be consistent with Reference 17 of Section 9.1.

This change is an administrative update to clarify that only the specific response to heavy loads (TXX-3659 / ML20072A945) is considered part of the FSAR and that future revisions to Design Basis Document DBD-ME-006 "Control of Heavy Loads at Nuclear Plants" are not considered part of the FSAR.

FSAR Amendment 110

SA-2020-012 EV-TR-2019-000901-4 (KJV):

Section 9.5.6.2:
This change reflects the ongoing staged replacement of the non-safety-related EDG starting air compressors - one compressor for each of the redundant starting air subsystems provided each of the two EDGs per Unit (total of eight). It is anticipated the overall installation period will be several years. Critical characteristics of the safety-related starting air receivers are unaffected by this modification. Each starting air receiver will continue to maintain the ability to support five (5) diesel starts and the minimum allowable receiver pressure Technical Specification limit remain unchanged throughout the installation period. The replacement air compressor design allows for the elimination of existing motor-driven air aftercoolers, unloader solenoid valves and associated circuitry and tubing, and the existing condensate drip traps. The FSAR will be updated in full upon completion of the modification when all EDG starting subsystems will have been modified. This activity is being done per Final Design Authorization Number 2017-000092-01.

SA-2017-022 EV-TR-2009-002875-40 (NWB):

Sections 7.5, 7.7, 11.5, TMI III.A, and Figures 7.7-14, 11.5-1, and III.A.1.2-2:
Update plant computer description following Plant computer replacement project.

SA-2019-004 EV-TR-2019-000901-1 (NWB):

Sections 8.3 and 9.5 and Tables 3.9B-10, 8.3-1, 8.3-2, 8.3-11, and 9.5-13:
UFSAR revisions to reflect the replacement of the Diesel Generator Starting Air Compressors, and also removal of the Starting Air Aftercoolers, Drip Trips, and Starting Air 3-Way Solenoid Valves.

SA-2019-012 EV-CR-2015-011094-7 (CBC):

Section 6.3.2.2.9.2:
The text is updated to reflect that the Safety Injection (ECCS to Cold Legs) check valves 2 inches and smaller are either spring loaded, lift piston types or nozzle check valve types. This change is supported by FDA-2019-000080-01. Both types of valve perform the design function and are subject to the same testing requirements.

SA-2020-003 EV-CR-2019-009290-8 (CBC):

Table 5.1-1B (Unit 2) Sheet 1 of 2:
The Unit 2 Pressurizer heater capacity (kW), has changed from 1731 to 1662 as heater #61 is defective and has been abandoned. This activity is being done per Final Design Authorization Number 2020-000040-01. This activity has no impact on the pressurizer design function as the minimum heater requirements are not affected.

SA-2020-013 EV-TR-2020-008801-1 (CBC):

Sections 9.2.1.10, 9.4B.2 and Table 8.3-11:
Removing obsolete information and designating two of three fire pumps as abandoned in place in the SWIS.

SA-2021-002 EV-CR-2018-002388-10 (CBC):

Sections 6.2.1.1.3.2, 6.2.1.1.3.11, and Tables 6.2.1-2, 6.2.1-3, 6.2.1-3A, 6.2.1-3B, 6.2.1-4, 6.2.1-9, 6.2.1-11, 6.2.1-12, 6.2.1-39, 6.2.1-41, 6.2.1-42, 6.2.1-43, 6.2.1-50, 6.2.1-51, 6.2.1-54:
The FSAR is updated to reflect the results of the re-analysis of the LOCA containment Pressure and Temperature in order to address Westinghouse NSALs (NSAL-06-6-R6, NSAL-11-5-R0, NSAL-14-2-R0) and concerns identified in CR-2018-002388 and CR-2019-002407. This change is supported by FDA-2021-000003-01. No physical changes to the plant resulted from updated analysis. This update does not adversely affect the design function of containment since the revised values do not violate the containment GDCs or equipment qualification requirements.

FSAR Amendment 111

SA-2021-003 EV-TR-2020-007054-1 (CBC):

Sections: 8.2, 8.3, F8.2-4, F8.2-5, F8.2-7
The description of the alternate startup transformers (XST1A and XST2A) and the switchyards in FSAR Section 8.2.1 is updated for consistency with FSAR Figure 8.2-1. FSAR Figure 8.2-4 is updated to correct an editorial error (change switch "17441" to "14741"). FSAR Figures 8.2-5 and 8.2-7 are deleted. A Text reference to the deleted figures is replaced with a reference to FSAR Figures 8.2-1 and 8.2-4. A reference to FSAR Figure 8.2-2 in FSAR Section 8.3.1 is replace with a reference to FSAR Figure 8.2-1 (Figure 8.2-2 was deleted in a previous FSAR Amendment).
These changes are clarifications and provide consistency within the FSAR. The deleted Figures are below the level of detail required by NRC RG 1.70-R2 (FSAR format and content)

SA-2021-005 EV-TR-2021-001647-2 (NWB):

Sections 3.2.2.2.d, 3.7B.2.8:
The UFSAR is updated to include the approval for the use of LOKRING fittings for Class 5 piping.

SA-2021-006 EV-TR-2021-002266-2 (CBC):

Section 5.4.1.4:
FSAR Section 5.4.1.4, "Tests and Inspections," is updated and simplified by removing excessive detail regarding reactor coolant pump casings. This detail is not required by NRC RG 1.70-R2 (FSAR format and content).

SA-2021-007 EV-TR-2018-005809-2 (NWB):

Sections 3.9N, 3B and 5.4:
Incorporate description of Unit 1 MSIP application to Reactor Vessel Nozzles performed in 1RF20.

SA-2021-010 EV-CR-2018-003408-2 (NWB):

Section 15.7.4.2 and Table 15.7.6:
Administrative removal of excessively detailed statements which are inconsistent with the Safety Analysis description of the fuel handling accident.

SA-2021-011 EV-TR-2020-002570-2 (NWB):

Sections 4.3.3 and 15.4.3.2 and Tables 1.6-1 and 4.1-2:
Update the UFSAR for the transition to the NEXUS/PARAGON/ANC9 nuclear design software.

FSAR Amendment 111

SA-2022-001 EV-TR-2019-000901-7 (NWB):

Section 9.5:
Removal of temporary tracking information statement after completion of EDG starting air compressor changes.
